Judges are few, and how very grateful exhibitors should be to those gentlemen who week after week go long journeys to out-of-the-way places to officiate. More judges are wanted, all will agree in thinking, and, what is more, more judges must be had. But we often pause to consider whether exhibitors go the right way to obtain them. Unfortunately men capable for the work do not abound. If a new hand does venture to make a trial every mistake he makes is made ten times more of in and out of print than if it had been made by a well-known hand. We must remember Rome was not built in a day, and a man must have practice before he can become a Teebay or a Hewitt. We have had two or three fresh hands this year, and they have done well, and we hope to see them in the like office again, and be as distinguished for their honesty in their awards as their power of picking out the best birds. Then, again, we are always glad to see a large staff of judges. We believe the awards would give more satisfaction if the judges had a practicable amount of work allotted to them. No man can satisfactorily make awards when he knows that he must hurry through the work to get it over by a given time.—W.

NORTHAMPTON SHOW OF POULTRY, &c.

We always look upon this Show as the Lenten one: it comes in mid-Lent, when other shows are over and the birds are all at home resting thankfully after many victories or doing penance for defeat. In the midst of this gloomy season Mr. Humphreys issues his schedule and prepares the great hall in the Corn Exchange for his poultry tournament, which comes like a feast day in the Lenten-tide. Just the very good and best birds which have won many prizes and generally acquitted themselves well are sent to Northampton for the gala day. The catalogue is numbered up to 1390, but we gather from a note at the "finis" that the total number of entries at this capital Show was 1514, taking which number from the former we may reckon that close on 130 entries were made and received late. We do not approve of this plan. It is not fair to those who enter early, and in this matter Oxford may set an example, who, in one year in particular, sent back close on two hundred entries to keep faith with exhibitors. We notice here at Northampton one lady's numbers were all A's and B's right through, and we were sorry to learn that her manager made a mistake in the day, and so was *hors de combat*.

Before commencing to criticise we must say one word on the excellency of the catalogues—well got up, and awards printed against the names. We wish all committees where it is possible would follow suit and print the awards in the catalogue. We were sorry to find some mistake had arisen with Mr. Turner about the Pigeon pens, and they were consequently not erected in time for Mr. Tegetmeier to finish his awards by daylight, which must account, we suppose, for a few alterations we should like to have made in the Pigeon awards. He had to judge alone, too, for Mr. Gresham did not arrive till he had finished his labours, which were very considerable. Many extra prizes were awarded, and we were glad to see it; but this Show could afford to be liberal from the great patronage it received.

Dorkings were all grouped together. The non-division of Dorkings and absence of Polish classes were the blots on the schedule, and we shall hope to see it remedied next year. Dorkings were as a whole disappointing. The winners were good, but nothing out of the common. The first and second hens were fine deep hens. 14 (Cheesman), also good. 11 (Lord Massy), a splendid hen, and cheap at catalogue price of 30*s*.

Cochins we called a good lot. They had six classes. Buffs were capital. The first cock good all round. Third we preferred to second, he was better in colour. 29 (Winwood), good, and so was 31 (Feast). In Buff hens, if the first-prize hen were honestly shown, and we almost think she was, she was a bargain at £5 5*s*., being a first-class bird. 48 (Leno) was, we believe, the cup hen at Oakham. She looks well. 43 (Sherwood), a capital pullet. In Black or Partridge cocks, the first was an old friend looking well. 55 (Whitworth), a nice Black. In hens, first, second, and third went to Blacks, and all good birds.

White cocks were ten in number. The first was a coarse bird, but soon claimed at £4 4s. The second and third were two fine cocks of spotless colour and good shape. White hens were good. The first-prize hen the same bird as we noticed at Kendal; second good; third poor. We preferred either of Mr. Woodgate's two highly commended hens infinitely. 86 (Feast), good.

In *Brahmas*, Lights came before the Darks. All the winners were well placed, the second running first close. In hens the first was a beauty; the second down behind, we fear. She has been a grand one. Third very pretty. 130a (Dean), a good bird. 110 (Boissier), a very grand hen. Dark Brahmas did not like being classed behind their Light brethren perhaps, for they did not muster so strongly. We liked the second cock immensely, but he was very heavily feathered. Third a good bird. In hens the winning Dark was an old friend looking as well as ever. Her colour is not good, but she is splendid in size and fluff. The second was a well-marked hen, but bad in colour also. We have missed Mr. Lingwood's name of late in Dark Brahmas, and are sorry to learn, from a letter from him recently, that he is laid-up and has been for some time with one of those bad throats which have been so prevalent.

Malays were good. The third in cocks went to a new exhibitor, we fancy. We rejoice as much as Mr. Hinton does to see fresh names in the "abused" weeds. Malay hens were good too, especially the winners.

French mustered very well. Houdans are quite rivalling the Brahmas in popularity. The winning cocks were good, but we liked 177 (Dring) as well as any one of them, but his comb we conclude was objected to. The winning hens were capital, the first, if we mistake not, the grand hen that was passed over at Dorchester. 190 (Boissier), a capital hen. In French of any other variety good Crêves were first and second, and a capital La Flèche third. 208 (Dring), a grand cock of fine shape. In hens Crêves won all the prizes. The winners were good. In looking over the French classes it would seem to us as if the wrong heads had got on the wrong bodies, so many Crêves having Houdan combs, and *vice versâ*.

Spanish were wonderfully good. They made as two good classes as we have seen this season. The first cockerel was a beauty. 240 (Whitworth), good. Hens were a splendid lot, and all the birds well shown.

Game had six classes, and surely Mr. Matthews must almost have surpassed himself. He won the six firsts with his six pens. "That is the way to do the trick," as the portly man said who had got near twenty pens at the Show and only won a hatful of useless "highly commendeds." We will say all his winners were absolutely perfect, and so speak of all the firsts once and for all this time. 267 (Fitz-Herbert), a capital Black Red cockerel. Good, too, was this gentleman's hen which won second, and only in at 42s. The third Brown Red cock was a little too deep in colour, or else of grand shape. 322 (Whitworth), disqualified for pulled hackles. We wish "Elijah" had left him at home. The second and third Duckwing hens were very nice. We liked the latter especially.

Hamburghs were a good lot, well judged and mostly well shown. The Gold-spangles very good, the first cock being perfection, as, too, was the first hen. What a grand pair they would make! Gold-pencilled were very fine. We are not sure, though, that we did not prefer Mr. Beldon's third to his second cock. Then hens which won seemed well placed, the first hen especially well marked. In Silver-spangles all the winners were good and well chosen, and Silver-pencils made two of the best classes we have seen of the breed for a long time. The first was superb in tail—quite a Goitstock model. 424 (Long), a nice cock. 431 (Norton), a very good bird. The markings of all the prize hens were very good. 439 (Feast), a very pretty bird. Black Hamburghs also mustered well, and the quality was really first-class. The first pullet was a beauty to all appearance, and a bargain to someone at 30s.

The two Variety classes were very large and wonderfully good. In cocks Poles won all the prizes. Gold, Silver and Gold, and all good. 473 (Norwood), the best White-crested Black Poland cockerel we have seen for many a long day, and we should have liked it to have had an extra prize. 474, a nice Silver Poland cock. In hens, Golden Poles were first and second, and a miserable Cuckoo Cochin third, and extra third a nice Sultan. 486, a nice Minorca. 495 (Beldon), a very beautiful Silver Poland hen.

The Sale classes were large, and the prizes seemed judiciously distributed. Many of the birds changed hands.

The *Ducks* did not make large classes. The first Ayleaburys were only 60s., and the third 30s., and both from Aylesbury. Rouens were good, and we were glad to see new names in the list. In Variety Duck class Mandarins were first and second and Carolinas third, all nice specimens. Writing of Fancy Ducks, we are sorry to have to record the death of the cup Japanese Teal drake at Bristol. It was one of the very few specimens of the breed in England, and we had hoped they would have got more general, being such a charming little breed for ornamental waters.

Game *Bantams* were very good, Black Reds the best; Mr. Hall winning first in both classes. In variety Game Bantam cocks Duckwings were first, second, and third; and in hens Piles first and third, with a Duckwing between them. Black and White Bantams made two fair classes, the first-prize cockerel being very lustrous and good. In Variety Bantams Mr. Leno walked his Laced in without much opposition, Silvers, Gold, and Silvers winning in the order named.

The Pigeons were very good. The White Pouters were nicely shown and well selected. 778 (Baker), a very nice cock. In the next Pouter classes were some good Blues and Blacks; the first Blue cock especially struck our fancy. In Pouters Any other colour, Reds won all the prizes, but they were not an Al lot. Old Carriers were disappointing. Mr. Yardley's winners were, however, good. In Carriers hatched last year we preferred Col. Hassard's two cocks to either second or third-prize birds. The hens seemed well placed. Barbs were good; a nice old Yellow first. Third, a good Black, which we preferred to second. Short-faced Tumblers were a charming lot; the second-prize Almond a sweet little bird. In Variety class of Tumblers were one or two good clean-cut Balds. A very pretty silver Muff won an extra second. Foreign and English Owls were two large classes. A lovely White was first in the Foreign class, and a good Blue in the English, while a truly exquisite Silver was second, and third again a nice Blue. Turbits were also splendid, but we did not much care for the judging. We thought 927 (Jones) should have been higher. In the next Turbit class the winners were good, but Mr. Cresswell's Shell-crested Black which won third was not nearly so good as his unnoticed pen 938, which we thought should have been at least second. Dragoons made two very large classes, and the quality was admirable. How popular they do seem! Jacobins were good. 990 (Nottage), a good Red. Fantails were lovely, Whites winning all the prizes. 1026 (Yardley), a fine Blue. 1027 (Cresswell), a wonderfully good young White. 1031 (Loversidge), a nice White. Antwerps were numerous, and Mr. Tegetmeier seemed at home among them. Nuns a large class. We thought they would have observed the season too closely to have come out so strongly. Magpies wonderfully good, and the whole lot were commended. In the Variety class a neat Red Swallow was first, in at 40s.; third a good Trumpeter. 1129, a cheap Archangel (Wingfield), for 35s. 1131, a good Blue Swallow. An interesting local class finished-off this department.

We can only congratulate this hard-working Committee on their general success, and the admirable selection of days, avoiding the objectionable plan of the Show being held over a Sunday. We give full awards below.

Dorkings.—*Cock.*—1, H. Feast, Swansea. 2, S. W. Hallam, Whitwick. 3, W Roe, jun., Newark. *hc*, T. Potter, jun., Trowell. *c*, J. Hedges. *Hen.*—1, W. H. Crabtree, Levenshulme. 2, W. Roe, jun. 3, H. Feast. *hc*, Lord Massy, Daventry; R. Cheesman, Westwell; S. Brierley, Ending.

Cochin-China.—*Cinnamon or Buff.—Cock.*—1, G. H. Procter, Durham. 2, Mrs. E. Allsopp, Worcester. 3, W. A. Burnell, Southwell. *hc*, D. Young, Lesmington; Mrs. Bentley, Teddington; C. Taylor; E. Winwood, Worcester; H. Feast; H. Piper, Oxford; Mrs Nicholson, Machon Bank. *Hen.*—1, H. Robinson, Sheffield. 2, T. Sherwood, Crowfield. 3, G. F. Umpleby, Boroughbridge. *hc*, R. Fowler, Birmingham; T. Sherwood; Mrs. E. Allsopp; M. Leno, Markyate Street, Dunstable; T. H. Turner, Sheffield.

Cochin-China.—*Partridge or Black.—Cock.*—1, W. H. Crabtree. 2, F. C. Bentinck, Cambridge. 3, J. Franklyn, Terrington, King's Lynn. *hc*, W. Whitworth, jun; F. C. Bentinck; W. & T. Holt. *c*, Hon. & Rev. C. T. Vernon. *Hen.*—1 and 2, W. & T. Holt, Accrington. 3, W. Whitworth, jun., Longsight, Manchester. *hc*, H. Feast.

Cochin-China.—*White.—Cock.*—1, J. H. Nichols. 2 and 3, R. S. S. Woodgate, Pembury, Tunbridge Wells *Hen.*—1, G. H. Procter. 2 and 3, Rev. A. Warde, Little Horsted Rectory, Uckfield. *hc*, H Feast; R. S. S. Woodgate (2).

Brahma Pootra.—*Light.—Cock.*—1, P. Haines, Palgrave. 2, W. H. Crabtree. 3, R. E. Horsfall, Liverpool. Extra 3, Mrs. Peet, Sharnbrook. *hc*, S. Lucas, Hitchin; J. H. Butler, Birmingham; W. T. Bromley, Daventry; E. Scammell, Trowbridge. *c*, E. Mannooch, Pinner. *Hen.*—1, Mrs Peet 2, W. H. Crabtree, Extra 2 and 3, P. Haines. *hc*, R. A. Boissier; S. Lucas; R. Bird, Fulham; J. H. Butler; T. A. Dean, Marsden, Hereford.

Brahma Pootra.—*Dark.—Cock.*—1, Rev. G. W. Joyce, Tavistock. 2, J. F. Smith, Sheffield. 3, W. H. Crabtree. *hc*, Miss Jacques, Richmond; A. Bamford, Middleton; C. Taylor; H. Robinson. *Hen.*—1, W. H. Crabtree. 2, J. W. Peake. 3, J. F. Smith. *hc*, W. Prentice, jun., Thrapstone; T. Stretch, Ormskirk. *c*, J. S. Clarke, Ounsdle.

Malays.—*Cock.*—1, R. Hawkins, Sunderland. 2, G Burnell. 3, Lady D. Yeoman, Whitby. *Hen.*—1, R. Hawkins. 2, G. Burnell. 3, J. Richardson, Longbborough.

Houdans.—*Cock.*—1, W. Whitworth, jun. 2, Mrs. Vallance, Sittingbourne. 3, J. L. Hawkins. *hc*, R. A. Boissier, Penshurst; W. Dring, Faversham; Miss Jacques; S. W. Thomas, Sketby (2). *Hen.*—1, Mrs. Vallance. 2, S. W. Thomas. 3, W. Whitworth, jun. *hc*, R. A. Boissier; W. Dring; A. Ogden, Ashton-under-Lyne; H. Feast.

French.—*Any other variety.—Cock.*—1, W. H. Crabtree. 2 and *c*, C. H. Smith, Parkfields, Derby. 3, Rev. N. J. Ridley, Newbury. *hc*, W. Dring; W. Cutlack, jun., Littleport; E. Clarabut, Peterborough; Mrs. Cross, Brigg. *Hen.*—1, W. Cutlack, jun. 2, W. H. Crabtree. 3, H. Beldon, Goitstock. *hc*, Mrs. M. Wicks, Appleby, Brigg; Rev. T. C. Beasley, Dallington; E. Brown, Sheffield; J. H. Nichols.

Spanish.—*Cock.*—1, D. M. Mills, Newport Pagnell. 2, H. Beldon. 3, Mrs. E. Allsopp. *hc*, W. Cropley, Stratford; W. Whitworth, jun.; H. Goddard, London; Mrs E. Allsopp. *Hen.*—1 and 2, Mrs E. Allsopp. 3, E. Brown. *vhc*, J. Pitt, Wolverhampton. *hc*, J. T. Parker, Northampton; C. W. Brierley, Middleton; H. Beldon. *c*, W. G. Henry, Dublin.

Game.—*Black-breasted Red.—Cock.*—1, S. Matthew, Stowmarket. 2, J. Mason, Worcester. 3, R. H. Tyte, Minchinhampton. *hc*, G. H. Fitz-Herbert, Sevenoaks; H. Butler, Heanor; A. C. Swain, Radclive. *Hen.*—1, S. Matthew. 2, G. H. Fitz-Herbert. 3, R. J. Pratt, Charlbury. *vhc*, J. Mason. *c*, R. H. Tyte; H. Feast

Game.—*Brown-breasted Red.—Cock.*—1, S. Matthew. 2, H. E. Martin, Fakenham. 3, J. Cook, Worcester. *hc*, G. F. Ward, Wrenbury; C. W. Brierley. *Hen.*—1, S. Matthew. 2, J. Cock. 3, G. F. Ward. *hc*, A. Peake, Oakham; C. W. Brierley; J. Richardson. *c*, F. Glanville, St. Austell.

Game.—*Any other colour.—Cock.*—1, S. Matthew. 2, J. Mason. 3, E. Winwood. *hc*, G. F. Ward; E. Bell, Burton-on-Trent; C. W. Brierley. *Hen.*—1, S.

Matthew. 2, T. Whittaker, Melton Mowbray. 3, E. Winwood. *hc*, B. Mollett, Balham.

HAMBURGHS.—*Golden-spangled —Cock.*—1, Duke of Sutherland, Stoke-on-Trent. 2, H. Pickles, Earby, Skipton. 3, H. Beldon. *hc*, T. Blakeman, Wolverhampton; J. Long, Bromley Common. *c*, S. W. Evans, Sutton Coldfield; D. Simons; T. Love, Northampton. *Hen.*—1, H. Beldon. 2, S. W. Hallam. 3, Mrs. T. Blakeman. *hc*, H. Pickles; T. Love.

HAMBURGHS.—*Golden-pencilled.—Cock.*—1, H. Pickles 2 and 3, H. Beldon. *hc*, W. Speakman, Nantwich; T. Dixon, Selkirk. *c*, T. Wild, jun. *Hen.*—1, C. Judson, Southwark Street, London. 2, W. Clayton, Keighley. 3, H. Beldon. Extra 3, W. E. Snell, Barrodes. *hc*, W. Speakman; H. Beldon; W. Linton, Selkirk; Duke of Sutherland.

HAMBURGHS.—*Silver-spangled.—Cock.*—1, H. Beldon. 2, Duke of Sutherland, 3, H. Pickles. *hc*, J. Carr, Swansea; J. Long; H. Beldon. *Hen.*—1, H. Pickles. 2 and *vhc*, H. Beldon. 3, W. T. Lindsey, Great Yarmouth.

HAMBURGHS.—*Silver-pencilled.—Cock.*—1, H. Beldon. 2, H. Pickles. 3, H. Feast. *hc*, J. Long; Duke of Sutherland; H. Beldoo; B. Nortoo, Town Malling. *c*, R. W. Bracewell, Skipton. *Hen.*—1, H. Pickles. 2, H. Beldon. 3, Duke of Sutherland. *vhc*, H. Feast. *hc*, J. Long; R. W. Bracewell; H. Beldon.

HAMBURGHS.—*Black.—Cock.*—1, H. Beldon. 2, H. Pickles. 3, Duke of Sutherland. Extra 3, H A Clarke, Aspatria. *hc*, T. A. Wright, Great Yarmouth; O. Thompson, Kettering; T. Bush, Bristol; J. Foster, Kettering. *c*, J. Long. *Hen.*—1, W. H. Shackleton, Bradford. 2, T. Bush. 3, H. Pickles. *hc*, J. Long; H. Beldon; Stott & Booth, Bury.

ANY OTHER VARIETY.—*Cock.*—1 and 2, H Beldon (Polaud). 3, A. & W. H. Silvester, Sheffield. *hc*, J. Croote, jun., Bridgewater (Minorca); T. Norwood, Salisbury (White-crested Black Poland); G Lias, Par Station (Silver Poland); Mrs. C. Gray, Northampton; Mrs. G. W. Boothby, Louth; J. Long; A. & W. H. Silvester; H. Feast.

ANY OTHER VARIETY.—*Hen.*—1, A. & W. H. Silvester. 2, G. W. Boothby (Golden Poland). 3, H. Feast; J. Watkin, Northampton (Cochin-China). *vhc*, H. Beldon (Poland) (2); J. J. Watkin (Cuckoo Cochin). *hc*, J. Croote, jun. (Minorca); Miss E. Vernon, Kettering (Golden Poland); T. C. Newbit (White-crested Black Poland).

SPECIAL SELLING CLASS.—*Any variety except Bantams and Ducks —Price not to exceed 30s.—Cocks.*—1, R. Fowler (Buff Cochin). 2, P. Ogilvie, Hambledon (Dark Brahma). 3, Lord Massy (Light Brahma). Extra 3, A. C. Swain (Black Red); S. Sambrooke, Chipping Campden. *vhc*, M. Leno (Brahma) *hc*, R. Cheesman (Coloured Dorking); W. A. Burnell (White Cochin); T. J. Harrison, Kendal (Buff Cochin); J. T. Parker (Spanish); P. Ogilvie (Buff Cochin); J. Holme, Kettering; T. A. Dean; H. Yardley, Birmingham.

SPECIAL SELLING CLASS.—*Any variety except Bantams and Ducks.—Price not to exceed 40s.—Hens.*—1, J. T. Parker (Spanish). 2, J. H. Nichols, Lostwithiel (White Cochin). 3, J. Holme. Extra 3, W. A Burnell (Buff Cochin); J. T. Parker (Spanish). *hc*, Lord Massy (Light Brahma); R. Cheesman (Colonred Dorking); Miss A. Binney, Wallingford (Light Brahma); J. Honey, St. Austell (Brown Red Game); T. Love (Golden-spangled Hamburgh); J. H. Butler (Brahma); E. G. Keay, Birmingham; R. Newbit; J. Pitt (Spanish); W. Roe, jun. (Dorking); H. Yardley; Mrs. E. Allsopp (Spanish); M. Leno (Brahma); J. Richardson (Duckwing); T. Hancock, Northampton; T. H. Turner; Mrs. Nicholson.

SPECIAL SELLING CLASS.—*Any variety except Bantams or Ducks —Price not to exceed 60s.*—1, H. Pickles. 2, M. Leno (Brahma). 3, W. F. Addie, Preston Extra 3, Rev. R. Fielding, Muggington Rectory, Derby (Partridge Cochin); R. Newbit. *hc*, R. Cheesman (Colonred Dorking); Mrs. Cross (Crève-Cœur); J. T. Parker (Spanish); E. G. Keay; W. Bentley, Holmfirth; J. Bassett, Lostwithiel (Spanish); J. Nelson, Hexham; Mrs. E. Allsopp (Buff Cochin); C. Bloodworth, Cheltenham (Buff Cochin); J. Holme; Furness & Sudall, Rawtenstall.

SPECIAL SELLING CLASS.—*Any variety of Duck.—Price not to exceed 30s.*—1, T. Kingsley (Aylesbury). 2 and 3, J. Hedges (Aylesbury). *hc*, J. Long (White Call).

SPECIAL SELLING CLASS.—*Any variety of Bantams.—Price not to exceed 30s.*—1, R. H. Ashton (Black). 2, Shumach & Daft. 3, R Wingfield. Extra 3, G. F. Ward. *hc*, T. E Thirtle, Lowestoft (White); R. Newbit; M. Leno (Laced). *c*, T. E. Thirtle (Black).

LOCAL CLASS.—1, W. Nottage, Northampton. 2, J. T. Parker (Spanish). 3, T. Wright, Northampton. *hc*, C. T. Higgins, Northampton.

DUCKS.—*Aylesbury.*—1, J. Rodwell, Msidsmorton. 2, T Kingsley, Tring. 3, J. Hedges, Aylesbury. *hc*, T. Kingsley; T. Plumb, Northampton.

DUCKS.—*Rouen.*—1, Lady G. Gordon, Peterborough. 2 and 3, Hon. Mrs. Vernon. *hc*, Mrs. Bayard, Gwernydd Berriew.

DUCKS.—*Any other variety.*—1, A. & W. H. Silvester. 2 and 3, M. Leno. *hc*, T. Walton, Northampton; E. W. Southwood, Fakenham.

GAME BANTAMS.—*Black-breasted Red.—Cock.*—1, G. Hall, Kendal. 2, J. Mayo, Gloucester. 3, S. Beighton, Southwell. Extra 3, Shumach & Daft, Southwell. *vhc*, W. Griffin, Ashby-de-la-Zouch. *hc*, T. W. Anus, Clapham; Capt. T. Wetherall, Kettering; T. Dawson, Epworth. *c*, A. Newton. *Hen* —1, G. Hall. 2, S. Beighton. 3, J. Calladine, Heanor. *hc*, Shumach & Daft; J Randall, juo.,

GAME BANTAMS.—*Brown-breasted Red.—Cock.*—1 and 2, T. Barker, Burnley. 3, G. Hall. *hc*, A. Cameron, Rotherham. *Hen.*—1 and 2, S. Beighton. 3, W. S. Marsh, Deal. *hc*, T. Barker; J. Mayo; G F. Ward. *c*, H. A. Clark.

GAME BANTAMS.—*Any other colour.—Cock.*—1, T. Dawson. 2, G. Hall. 3, Shumach & Daft. *hc*, T. Barker; G F. Ward; S. Beighton. *Hen.*—1 and 3, T. Barker. 2, Master A. Frew, Sinclairtowo, Kirkcaldy. *hc*, E. W. Southwood.

BANTAMS.—*Black or White.—Cock.*—1, H. Beldon. 2, Milner & Beanland. 3, R. H. Ashton, Mottram, Maochester. *hc*, W. H. Shackleton; J. Mayo; A. Smith, Halifax. *Hen.*—1, Milner & Beanland. 2, H. Beldon. 3, Wells and Sherwin, Ripon. *hc*, W. H. Shackleton; Wells & Sherwin; A. A. Vander Meersch, Tooting, London; A. Smith; J. H. Law, Birmingham.

BANTAMS.—*Any other variety.—Cock.*—1 and 2, M. Leno. 3, Miss B. B. Frew, Kirkcaldy. *Hen.*—1 and 2, M. Leno. 3, Miss R. C. Frew. *hc*, J. T. Hincks.

PIGEONS.

POUTERS.—*White.—Cock.*—1, Mrs. Ladd, Calne. 2, W. Nottage. 3, R. Ashton. *hc*, J. Baker, Kew Bridge. *c*, G Foster, Northampton. *Hen.*—1, Mrs. Ladd. 2, R Ashton. 3, J. Baker. *c*, W. Nottage.

POUTERS.—*Black or Blue.—Cock.*—1 and 3, W. Nottage. 2, J. Baker. *hc*, H. Yardley. *Hen.*—1, W. Nottage. 2, J. Hairsine, Hull. 3, J. Baker. *hc*, J. Baker; W. Nottage.

POUTERS.—*Any other colour.—Cock.*—1 and 3, W. Nottage. 2, J. Baker. *Hen.*—1, 2, and 3, W. Nottage.

CARRIERS.—*Cock.*—1, H. Yardley. 2 and 3, J. Baker. *c*, J. Stiles, jun., Kettering. *Hen* —1, H. Yardley. 2, J. Baker. 3 J Stanley, Blackburn.

CARRIERS.—*Young Cock.*—1, H. Cartwright, Edghaston. 2, J. Stanley. 3, J. Baker. *hc*, Col. F. C. Hassard, Sheerness (2); J Baker. *c*, W. Massey, Spalding. *Young Hen.*—1, J. Baker. 2, H. Cartwright. 3, J. Gardner, Preston. *hc*, C. E. Chavasse, Sutton Coldfield; H. Cartwright; J. Baker; J. Stanley; J. Walker, Burslem. *c*, Mrs. Ladd.

BARBS.—*Cock or Hen.*—1 and *c*, J. Baker. 3 and *vhc*, H. Yardley. 2, W. Massey.

TUMBLERS.—*Short-faced.—Cock or Hen.*—1, H. Yardley. 2, A. & W. H. Silvester. 3, J. Baker *hc*, A. & W. H. Silvester; J. Gardner. *c*, J. F. While, Birmingham; H. Yardley (2); W. R. Pratt, Oxford

TUMBLERS.—*Any other variety.—Cock or Hen.*—1, R. Woods, Mansfield. 2, W. Tedd, Birmingham. Extra 2, C. E. Chavasse. 3, R. Woods. *hc*, A. & W. H. Silvester (2); R. Woods; W. Tedd (2). *c*, J. Kendrick, jun., Redditch; J. Barker.

OWLS.—*Foreign.—Cock or Hen.*—1, 2, and 3, J. Baker. *hc*, T G. Sprnot, Boundary Road, London; S. Lawson, Preston; P. H. Jones, Fulham, London.

OWLS.—*English.—Cock or Hen.*—1, J. Gardner. 2, P. H. Jones. 3, S. Lawson. Extra 3, E. Lee, Nantwich. *hc* T. Sprnut; F. P. Bulley, Oxford; R. Shillitoe, Hitchin; H. W. Weaving; W. G. Henry; S. Lawson. *c*, F. Steel, Halifax.

TURBITS.—*Blue or Silver.—Cock or Hen.*—1, W. G. Henry. 2, E. A. Seale, Kilpohhin, Dublin. 3, J. Baker. *hc*, C. W. Washbourne, Gloucester; T. S. Stephenson, Beverley; T. Homes, Lower Sydenham; P. H. Jones.

TURBITS.—*Any other colour.—Cock or Hen.*—1, E. A. Seale. 2, T. S. Stephenson. 3, O. E. Cresswell, Early Wood, Bagshot. *hc*, C. A. Crafer, Wallington; A. & W. H. Silvester; E. A. Seale; J. Baker (2); W. Tedd. *c*, E. A. Seale; F. Steel.

DRAGOONS.—*Blue.—Cock or Hen.*—1, J. Baker. 2 and 3, R. Woods. *hc*, R. Woods (2); Powell & Crane, Oxford (2); W. Bolshaw, Northampton. *c*, R. Woods; H. Yardley.

DRAGOONS —*Any other colour.—Cock or Hen.*—1, J. Atkins. 2, J. Gardner. 3 and Extra 3, R. Woods. *hc*, Wells & Sherwin; J. Atkins, Bedford. *c*, A. McKenzie; S. Cliff, Nantwich.

JACOBINS.—*Red.—Cock or Hen.*—1, J. Baker. 2, T. Holt, Bradford. 3, E. North, Leeds. *hc*, W. Nottage; T. Holt; J. Gardner.

JACOBINS.—*Any other colour —Cock or Hen.*—1, T. Holt. 2, E. A. Seale. 3, S. Lawson *hc*, E. A. Seale; R. Woods.

FANTAILS.—*Cock or Hen.*—1 and 2, E. A. Seale. 3, J. Walker, Newark. *hc*, H. Yardley; O. E. Cresswell; J. F. Loversidge, Newark. *c*, O. E. Cresswell.

ANTWERPS.—*Short-faced —Cock or Hen.*—1, F. Woodhouse. 2, J. Gardner. 3, J. F. While *hc*, A. Carruthers, Luton; H. W. Weaving, Oxford; C. E. Chavasse; H. Yardley.

ANTWERPS.—*Long-faced or Homing.—Cock or Hen.*—1, Scragg & Valters, Oxford. 2, Miss Perrin, Northampton. 3, W. R. Pratt.

NUNS.—*Cock or Hen.*—1, E. A. Seale. 2 and 3, W. Brown, Northampton. *hc*, J. Baker; W. Tedd.

MAGPIES.—*Cock or Hen.*—1, W. Nottage. 2, H. W. Webb, Lower Sydenham. 3, P. H. Jones.

ANY OTHER VARIETY.—*Cock or Hen.*—1, H. Draycott, Leicester. 2, A. & W. H. Silvester. 3, A. A. Vander Meersch. Extra 3, W. Tedd. *hc*, A. & W. H. Silvester; H. W. Webb; H. Yardley; R. Wingfield; F. Steel (2). *c*, A. & W. H. Silvester.

SPECIAL SELLING CLASS.—*Cock or Hen —Price not to exceed 3's.*—1, J. Barker. 2, Mrs. Ladd 3, W. G. Henry. *hc*, H. Lionet, Northampton; F. P. Bulley; H. W. Weaving; Mrs. Ladd; A. Perry, Hardingstone; E. North; H. Yardley; W. Massey; W. Tedd. *c*, W. Nottage.

SPECIAL SELLING CLASS.—*Cock or Hen.—Price not to exceed £5* —1 and 3, H. Yardley. 2, W. Nottage. *hc*, Mrs. Ladd; E. North; J. Stiles, jun.; J. Baker. *c*, J. Currie, Worcester.

SPECIAL SELLING CLASS.—*Price not to exceed 40s.*—1, Mrs. Ladd. 2, W. Nottage. 3, H. Draycott. Extra 3, W. Massey. *hc*, C. H. Buckland, Reading; W. G. Henry; H. Draycott.

LOCAL CLASS.—*Any variety.—Cock or Hen.*—1, W. Nottage. 2, G. Foster. 3, W. Brown. *hc*, W. Nottage; C. Hillier. *c*, W. Nottage.

RABBITS.

LOP-EAR.—*Self-colour.—Buck or Doe.*—1, H. Kendrick, Walsall. 2, Dr. Boden, West Hartlepool. 3, F. & E. J. Fell, Blackburn.

LOP-EAR.—*Broken Colour.—Buck or Doe.*—1, J. Irving, Blackburn. 2, Dr. Bodeo. 3, F. Lovehand, North Street, London, N.W. *vhc*, J. Hodson, Northampton; B. Greaves, Cleethorpes; F. Lovehand. *hc*, T H. Jones.

ANGORA.—*Buck or Doe.*—1 and 3, H Swetman, Fulford. 2, T. Garner, Northampton. *vhc*, O. Thompson. *hc*, M. Kew, Market Overton.

HIMALAYAN.—*Buck or Doe.*—1, C. G. Mason, Rochdale. 2, F. Sabbage, Northampton. 3, J. Pickworth, Spalding. *vhc*, Dr. J. D. Eames, Great Driffield. *hc*, Dr. J. D. Eames; J. Garner. *c*, J. Milverston, Northampton; J. Hallas.

DUTCH.—*Buck or Doe.*—1, H. Sabbage. 2, B. Greaves. 3, T. Garner. *vhc*, H. E. Gilbert, Rugby; W. Donkin, Driffield. *c*, Mrs. H. Pickworth; A. Budson, Hull.

SILVER-GREYS.—*Buck or Doe.*—1, A. Hudson. 2, J. Firth, Bramley. Extra 2, Miss Mortimer, Rudhall, Ross. 3, J. Hallas. Extra 3, H. W. Wright, Shepherd's Bush, London. *vhc*, E. Ames, Ash Grove, London, E.; Miss Mortimer; E. Robinson, Kettering; T. Schofield, Manchester. *hc*, R. A. Boissier; W. Clappen, Cirencester; G. Farrar, Bedford. *c*, J. Pickworth; A. W. Whitehouse, Northampton.

ANY OTHER VARIETY.—*Buck or Doe.*—1, P. Ogilvie. 2, J E. Pilgrim, Hinckley. 3, Rev. T. C. Beaseley, Dallington. *vhc*, S. Ball, Bradford; T. H. Dows, Boston. *hc*, Mrs. H. Pickworth; J. T. Billet, jun., Richmond; G. C. Levett, Soham; J. Tebbutt, Northampton; J. Hallas; B Greaves. *c*, R. Bowes.

SPECIAL SELLING CLASS.—*Buck or Doe.—Lops excepted* —1, P. Ogilvie. 2, C. Bryant, Bedford. 3, G. Johnson, Kettering. *vhc*, M. A. Hudson; T. Garner. *hc*, D. Craike.

SPECIAL SELLING CLASS.—*Lop-ear.—Buck or Doe.*—1, H. Kendrick. 2, A. McKenzie. 3, F. Loveband. *hc*, G. Adams, Northampton; F. Loveband.

LOCAL CLASS.—*Buck or Doe.*—1, A. W. Whitehouse. 2, J. Tebbutt. 3 and *hc*, F. Sabbage.

CATS.

LONG HAIR.—*Male.*—1, H. N. Wetherall, Kettering. 2, W. Prentice, jun., Aldwinkle, Thrapstone. 3, Miss Pell, Northampton. *c*, W. Bradshaw, Northampton; B. Cox, Northampton. *Female.*—1, Miss M. Wetherall, Kettering. 2, — Faulkner, Northampton. 3, J. W. Howard, Northampton. *hc*, B. Cox. *c*, H. N. Wetherall.

TABBIES.—*Male or Female.*—1, F. Coles, Northampton. 2, F. Baxter, Bath Place, London. 3, J. J. Phipps, Earl's Barton. *hc*, C. F. Smith, Tabernacle Row, London; Mrs. Roberts, Spratton Vicarage, Northampton.

ANY OTHER VARIETY.—*Male or Female.*—1, F. Longland, Northampton. 2, Mrs. C. Gray. 3, Mrs. Slater, Northampton. Extra 3, F. Coles. *hc*, Mrs. H. L. Cocksedge, Bury St. Edmunds. *c*, S. Parberry, Kingsthorpe.

JUDGES.—*Poultry:* Mr. R. Teehay and Mr. J. Dixon. *Pigeons:* Mr. W. B. Tegetmeier and Mr. F. Gresham. *Rabbits:* Mr. E. Hutton. *Cats:* Mrs. A. Pell and Miss Beasley.

THE MEALY POUTER.

I HAVE seen in the columns of a contemporary Mr. Wallace's letter under the above heading. He starts with the conclusion that I am both questioner and answerer referred to in the "Letter Box" of this Journal. To make use of Mr. Wallace's own words, I give his conclusion the most "unqualified contradiction." I know neither one nor other, but in common with many others was very much amused at the pithy style of the reply. The letter referred to shows once more how a drowning man will catch at a straw, the complaint from beginning to end is, that I was never a member of the North British Columbarian. Neither Mr. Ure nor myself ever was or ever had anything to do with its affairs, but I was one of the originators of the Society of which the North British is only the remains—in fact, it is the change of name alone upon which Mr. Wallace builds his "unqualified contradiction." The original name of this Society was the "Scottish Ornithological;" after Mr. Ure and myself retired along with others the name of this Society was altered to the "North British;" therefore anyone can at once see how by forgetting the change of name the mistake has occurred.

As to the last paragraph of Mr. Wallace's letter, "Why was there not a class for this bird at Edinburgh?" There was a class there, though not a separate one (see catalogue) at that time. The editor of the contemporary I refer to must put in his word, right or wrong. However, his friend Mr. Wallace unfortunately lets out that a Mr. McLean was the means of the class for Mealies being in the Glasgow Show in 1866 and 1867, thus showing that the claim of the editor is quite absurd. Now has the matter come out! Years before these two Exhibitions did Mr. Ure and myself debate the question and had it settled; and yet the suggestion came from "ourselves," says the editor in question! Further, he charges me with false representations, and he goes on to lead his readers to believe that I have been excluded from the columns of his journal, which is simply not true.

I do not wish to occupy space needlessly, therefore just a few words and then I have done. Along with Mr. Ure I sent a letter to this new contemporary in reply to a letter which appeared there, but they were such as hurt the feelings of the editor, and were likely, he thought, to do the same to the feelings of his friends to whom we were replying. We were told unless our replies were altered to suit they could not be put in print. Our replies were, "No alteration; please return our manuscripts." We had them returned, and forthwith, along with several others, have excluded ourselves from his columns and have left him.

In concluding this, to me, rather painful letter, allow me to say that I have always advocated a position for the Mealy Pouter, and some of those now loud in its praise at one time opposed me; but experience in breeding by it will more and more assure fanciers of its sterling value. Now, some of our readers may forget and others wonder what was the origin of all this correspondence. Let them, then, satisfy themselves by referring to No. 666, January 1st, 1874, of this Journal.—James Huie.

[We have another letter sustaining Mr. Huié's statement, which we are obliged to omit until next week.—Eds.]

NEGLECT AT THE OXFORD SHOW.

I exhibited some Jacobins there, and they contrived to lose a very nice hen from my hamper by neglecting to tie the lid. I received a telegram from the Secretary stating the bird had escaped on its way to the station. I wrote back to say that I should expect compensation for the loss of the bird, and that I considered it worth £3, but I have not been favoured with any other communication on the subject. The hamper had four compartments, three were tied; the one was not tied from which the bird escaped.—Alfred Heath.

[The Committee ought at once to pay for the bird. If you sue in the County Court they would be compelled to do so and to pay all costs.—Eds.]

LIGURIAN BEES.

I am glad to see that Mr. Pettigrew has thrown out a challenge (if I may use the term), whereby the merits of the Ligurian and the English bees may be tested and compared, but at the same time I would suggest that the merits of the wood and straw hives may at the same time be put side by side.

I also think the idea a good one for both parent hive and swarm to be put to the test, and then take notes of the weight either in bulk or run honey, or any other way that may be decided upon, the supers to be taken as run honey.

Now, the difficulty will be, To where are the bees to be sent? It will never do for the bee-keeper in the south to send his bees to the north, or the reverse. I would suggest that several places should be fixed upon; for instance, Rowsley near Chatsworth, the seat of the Duke of Devonshire, would be a good place for the bee-keepers thirty miles around Rowsley, and it is easy of access from all parts. The midland county apiarians might fix their own place, also those of the south country theirs; but we in the north, near Manchester, must get away from the smoke to compete with Worcester or Devon.

I intend sending some of my bees to Rowsley this spring to try for a good glass super of pure honey, which I have never yet obtained to exceed 20 lbs. upon my nine-bar Woodbury hive, but think I can do so from my Pettigrew 18-inch straw hive.—South Lancashire Bee-keeper.

OUR LETTER BOX.

Aylesbury Ducks (*An Ignoramus*).—If you do not intend to show till the end of the year, Ducks hatched next month will be early enough. Oatmeal is an excellent thing to give them when young. Small pieces of raw meat are also good for them when a fortnight or three weeks old. They should not be much in the water. It is most essential that Aylesbury Ducks should have pale flesh-coloured bills, and for that reason they should not be allowed to use ponds of stagnant water; such is often dark-coloured, and has an effect on the colour of the bill. When the ducklings are six weeks or two months old they may have whole oats, ship biscuits, or any other food; but if you mean to exhibit you will do well to give occasional feeds of raw meat. It gives growth and makes weight.

Books (*F. Hart*).—Brent's "Canary and other Song Birds." You can have it free by post from our office if you enclose 1s. 7*d*. in postage stamps with your address.

Piping Bullfinch (*Dora*).—You may vary the food of your Bullfinch by occasionally adding hemp seed to the canary and rape seed; not too much hemp, for instances are known of blindness and a change of plumage having been brought about when too freely fed upon hemp seed. Now and then give Bully some crushed plain biscuit, and watercress and small salad. The green food will tend to cleanse its stomach. Millet and grass seeds and a little piece of apple may likewise be given. Rape seed, prepared by being soaked a whole night in water, then the water strained off, and the seed partly dried by being rubbed in a cloth or towel, is a good diet for Bullfinches when they appear dull; and it would suit "Dora's" bird when in its melancholic fit. As to the quantity of food a Bullfinch should eat in one day, is a matter we cannot attempt to regulate. Much depends upon the appetite. Some birds waste more than they eat. Wastefulness is often caused through a want of discretion in too freely supplying the seed drawer or fountain with food, much of which is found mixed with the dirt or sand on the bottom of the cage. Were we to suggest the idea of only a certain portion of food being supplied some half-dozen times during each day, we are fearful we should be entailing too much trouble upon "Dora," and after all Master Bully would not eat much less daily than his 1½ oz. We do not consider the bird to be a glutton. Bullfinches in their wild and natural life seek for their food when they require it, and our advice is, Let the bird have its daily supply, with access to it at any time during the day when the appetite requires appeasing. Do not pamper the bird with delicacies such as pastry or sugar (we have no cause for supposing you do), and let it have a supply of grit-sand on the cage-bottom. Probably the bird has been kept too warm, and its system brought into a poor state through artificial heat. This may be the cause of its ruffled feathers. Let Bully have access occasionally to a good-sized cage, and if the bird will take a cold bath now and then so much the better. Cleanliness, exercise, pure water, and fresh air will do more for its health than the physician. Bullfinches are very fond of most kinds of berries and buds of trees. Examine the crevices and haunts of your Bullfinch's habitation, and see that there are no tormentors lurking about until the bird retires to roost—we will not say rest, for there is no rest when so plagued. Possibly this may be another cause of your bird appearing dull. Our Bullfinch is full of vigour, bright in the eyes, and close in feather. It has never been in artificial heat, and feeds daily upon hemp, rape, canary, millet, flax, groats, and broken biscuit, the same as our three sprightly Goldfinches. One cannot make themselves too familiar with a piping Bullfinch, for a chatty tongue will much speedier gain the good graces of Bully.

Feeding Stocks (*W. E. M.*).—The weather has been very trying for weak hives, many of which will have perished during the last three weeks' cold. We would advise you to watch carefully the operations of your bees in the different hives as soon as the weather becomes warm again. If you find pollen-gathering going on with tolerable vigour we should say, Let them alone, but continue to stimulate them with a little food given continuously. If the weak hives you speak of are not likely to maintain a separate existence, then you might join the survivors to one of the other stocks. Sometimes, however, the weak hives of one year become the strong hives of next year. We hardly think your weak hive lost life owing to your feeding, but we cannot speak positively, not knowing the full circumstances.

Belgian Hare Rabbit Eating Her Young (*G. A. R.*). — We do not think age has anything to do with the unnatural trick. It is the result of fever and internal derangement. The safeguard is always to keep a doe, especially when near kindling, liberally supplied with green food, and if with water so much the better. In rabbits, as in many other animals, no mistake is so fatal as high feeding for a time before parturition. We do not believe this would have happened had she had access to water and been well supplied with green food.

REMARKS.

3rd.—A dull grey day, but beautiful starlit night.

4th.—Rather misty in early morning, but very bright for two or three hours in the middle of the day, frosty and bright at night.

5th.—White frost in the morning, followed by a most beautifully bright day throughout. [day.

6th.—Rainy and dark, a few gleams of sunshine, but as a whole a dull damp

7th.—Fine morning; very bright about noon; but rain commenced about 3 P.M., and continued at intervals all day.

8th.—Very fine rain and very warm; fair from 1 P.M., when it was very bright; wind very high all night.

9th.—Rainy and windy in the early morning; but very bright before 10 A.M., and so continued; wind going down soon after noon.

The northerly winds gave way on Saturday the 6th, and the temperature rose rapidly, even the soil 1 foot deep rising nearly 10° during the week. The effect upon vegetation has been very marked.—G. J. Symons.

COVENT GARDEN MARKET.—March 10.

The supply has somewhat improved during the last few days, and that is the only alteration worth notice. The latest cargo of St. Michael's Pines was scarcely so good as those previously received, and the rates generally were lower. The ordinary Oranges from thence have been very unsatisfactory this season. Some samples of Tangerines, however, are very good.

From observations taken near London during forty-three years, the average day temperature of the week is 50.3°; and its night temperature 33.5°.

HARDY ANNUALS FOR ANY GARDEN.

THESE flowers afford delight to many by their graceful forms, quiet yet varied colours, and their simplicity of culture. They are specially adapted to the many who possess neither greenhouse nor frames, and whose circumstances preclude them making large purchases for their gardens of popular bedding plants. The owners of small unpretending gardens who have to plan and contrive to make this part gay, that bright, and the other sweet, often derive more actual enjoyment from their home plots than do those whose larger enclosures have the superintendence of professional care, the owners of which know nothing of the pleasure of preparing.

It is indeed true that there is more pleasure in working than the indolent dream of—more enjoyment in making our own homes attractive by our own hands than those trained in luxury can be made to understand. This is especially so in regard to gardening and the cultivation of flowers.

Look at the rosarian. He may have at his command sufficient assistance to produce the blooms ready for enjoyment; but that would not be enjoyment to him—he must have a share in the producing, or his choicest flowers will be deprived of a measure of their beauty, and be robbed of a portion of their delightful breath. No; he must himself labour to make his enjoyment full—he must be up with the sun of summer, pick out the worm from the buds, and sweep the green fly from the trusses, and then, when the perfect blooms unfold their beauty, is true enjoyment felt. But it is not even then complete. He must first call his friends to rejoice with him, or cut a dainty flower to cheer some cherished relative or imprisoned invalid before he can feel a fuller magnitude of the pleasures his garden gives. Or he must—as he has often done—hasten breakfastless away to some murky town and spread his work before the multitude, and if the fame of a "first prize" is awarded to his products then is the triumph complete; but if he fails, what disappointment! No; if the true lover of flowers sees others have flowers better than his own he will rejoice in their success, and buckle on his armour more firmly, will be up earlier and work harder, and the more persistent his application the greater his daily pleasure, and the more pleasant his dreams of hope and of future success.

The wife of a clergyman has written these lines—"I am an invalid, and my means are limited, but my simple garden is my solace; it is small—to you insignificant—but is a paradise on earth to me: tell me of some simple flowers that will grow at my bidding, and which will, with such trifling care as I am able to bestow with my own hands, make my home-walks pleasant."

That was a charming, a pathetic appeal from a delicate lady to a sunburnt son of toil. That lady enjoys her little garden with as great a relish as that bestowed on his by any noble in the land.

"Simple flowers," "come at my bidding," "grow with my own hands," "small garden," "limited means." What could be done under those conditions than to recommend hardy annuals? They were suggested, tried, and answered. Are there others in some degree similarly circumstanced? Possibly, and we pity them for nothing but their failing health. To these, therefore, the same advice may be given, and in the same way; thus—

Annuals are the flowers for you; but if your garden is overshadowed with trees, if the soil is poor and shallow and has not been well and deeply dug and manure added, or cannot be made good by digging at once, do not grow them. If when you receive this advice you keep it in hand and seek that of others, and defer to procure seed until late in April or in May, do not sow then. If you cannot find time when the plants are above ground to dress them round with lime and soot, or guano or sharp sand, to prevent the snails from devouring them, do not waste money in purchasing seed; and if you cannot find in your heart to thin-out the plants where too thick, you will not do justice to the plants or credit to my judgment, and therefore you had better let annuals alone.

As to the first condition, annuals will not flourish under trees or in poor shallow soil: it must be deep, good, and the site open. As to the second, if sowing is deferred until the weather becomes hot the plants cannot take firm and deep hold of the soil to procure the moisture they need, and their flowers are in consequence poor and their beauty transient. As to the third, if they are left to sustain unaided the attacks of slugs and snails very few will survive, and the molluscs will assuredly be the victors; and as to the fourth condition, if the plants are not thinned sufficiently or in time, we have no right to expect a vigorous and prolonged bloom any more than we should reckon that Turnips, Cabbages, or any other crop could attain perfection if left to struggle to maturity in the dense thick seed bed.

Now, bearing in mind these cardinal yet oft-neglected points of culture, we advise first of all to sow during the first fine weather of March Mignonette freely. Most gardens are too scarce of this sweet old plant. If sown early in good soil, and the plants eventually thinned to 5 or 6 inches apart, and it be cut freely and have the bulk of the seed pods clipped off, it will continue fresh all through the summer. The seed is best sown in shallow drills. Next, where a floral hedge is desired to act as a dividing line between one part of the garden and another, sow as soon as possible Sweet Peas. For this purpose they have no equal, and for cut bloom they are indispensable. They are frequently sown a month too late, and do what small garden Peas do under the same conditions—produce weak rows, small flowers, and poor crops. If in May a term of hot weather is foreseen, or whether it is or not, a row of tall Nasturtium seeds may be planted 3 inches apart at the foot of the row, and they will produce plants to run up the sticks, and form a hedge over the Peas and commence blooming just when the Pea flowers fail in July. These Nasturtiums will continue until the frost.

But perhaps a dividing row of lower growth may be preferred, and this may be provided by Larkspurs. A mixed row of the dwarf varieties has an effect all its own, and, if not of long duration, it is worth space for its attractive beauty during the month of July. A row of the branching varieties is taller and less dense, but will continue in bloom much longer than the former—indeed, if the seed spikes are clipped off, which is nice employment for a lady, the plants will grow and flower throughout the season. Early sowing and deep good ground are essentials of success, while late sowing and poor soil will lead to certain disappointment. Sow the seed in drills precisely as Onion seed is sown, and expect a reward.

Now for a few bed and border annuals. It must be conceded that if masses of bloom are required from June to October very few annuals will give them; but, what is sometimes forgotten, neither will all the bedding plants, as they are not established until July. But even for filling beds, a few annuals can be found which possess lasting qualities and a decision of colour which bedding plants cannot surpass.

Do you ask for a scarlet annual suitable for a bed which in colour is equal to a Geranium and nearly or quite as lasting, and we name Nasturtium Tom Thumb Scarlet; and one of which the flowers are more brilliant still by contrast with the bluish-green foliage, is King of Tom Thumbs. The seed should be sown to 2 to 3 inches deep about the middle or towards the end of March. Snails or slugs will not eat Nasturtiums, which is a great advantage. Severe spring frost will sometimes injure them, but if sown deeply the young plants will be safe by not appearing above ground until the weather is genial.

The scarlet being duly provided, what shall we have for a bed of rich blue? For this Convolvulus minor is named, selecting for the variety C. tricolor splendens. That is surpassingly rich in colour when had true, and makes a glorious bed, which will continue in beauty until destroyed by frost—that is, having deep soil and soakings—not sprinklings—of water if needed. It is beautiful for cut bloom, and the flowers last well in water. This is also a plant which slugs will not eat or a few degrees of frost injure. Sow the seed fully an inch deep, and thin-out the plants by degrees to a foot apart. As a long list of names commonly perplexes and bewilders more than benefits those requiring only a few distinct flowers, the aim is to be concise in selection; but we may name one other blue annual for bedding as adapted to wet localities, and that is the lovely Nemophila insignis. Where the summer rainfall is heavy there is no better bedding plant than this well-known annual. It is a rainy-season plant *par excellence*, and the deluge of 1872 in the wettest localities in Britain proved its worth. In hot seasons and dry localities it is short-lived, but in rainy districts it will grow and bloom for five or six months—a fact perhaps not generally known.

Passing on to a pink bedding annual, Saponaria calabrica has no rival. This plant possesses every quality of a good bedding plant—viz., dense habit, distinct colour, and continuous and free-flowering properties. With good soil-preparation and reasonable cultural attention this simple flower makes a perfect and charming bed.

We must now look for a white bed, which is not so easy to find amongst the hardy annuals. White-flowering annuals are to be found in plenty, but as a rule they are not lasting. The white variety of the foregoing and the old Sweet Alyssum, A. maritimum, are amongst the most suitable, and with high culture will last nearly all through the season. Clarkia and Candytuft may be, perhaps, more telling, but they are also more transient.

Of yellow bedding annuals there is no lack. The best are the Yellow Tom Thumb Nasturtium and Sanvitalia procumbens; there is a double variety of Sanvitalia, but the seed is much less certain to germinate freely than the single form, and for a bed the latter is recommended. A yellow annual with bolder flowers, also lasting if thinned and proper attention given, is the old Eschscholtzia.

The above are the principal colours which are required for bedding, but a crimson may be required. Linum grandiflorum makes a glowing bed, and is more lasting when the seed is sown in the bed at the end of March than when it is sown, as is frequently the case, on a prepared bed, and the seedlings are transplanted. To that is added the old Malope grandiflora. Seed of this sown in rich soil in March, the plants duly thinned out and eventually pegged down, culminates in a mass of extreme richness.

We have now found annuals suitable for bedding comprising white, scarlet, blue, pink, yellow, and crimson. They are all hardy, or may be treated as such, and are of free and easy growth. As to their lasting qualities this depends on the cultivator carrying out the hints of guidance above narrated. Annuals for mixed borders are set aside by the exigencies of space. Half-hardy annuals, as Stocks, Asters, &c., can all be grown admirably by the "glassless amateur," especially if seed is not sown until something more is heard from—A Surrey Gardener.

THE ROSE GARDEN IN WINTER.

"There's never anything about Roses now," I sighed this morning as with eager fingers I cut open the pages of our Journal. "I wonder why no one says a word about them week after week?" "Well, dear, you should write something yourself," said the lady who usually stands expectant at my elbow as the welcome pages are hastily run through in search of articles of interest, and inquires, "Anything in the Journal to-day?" The lady's "anything" has reference chiefly to Roses and fowls.

I remember that when first I began to ride my two hobby-horses I had great difficulty in inducing a certain person who shall be nameless to mount behind me. But now—— Well, I'm not quite sure that I haven't to ride behind myself! On one of the hobbies, at all events, my proper place appears to be the seat nearest the tail. How times do change! But how happy am I even in that position compared with those the comfort of whose ride is being continually spoiled by feminine attempts to drag them from the saddle. However, being mounted and incited (from behind on this occasion) to "go 'long," let us see where our "Rosinante" will carry us.

First of all let us congratulate ourselves and all growers of Roses on the glorious weather we are having at present. For nearly fourteen days frost and snow, and hail and sleet, easters and north-easters, with occasionally the pure breath of the northern king, have been doing their best to keep our too bumptious pets in their proper places. There is a proper time for everything, as the wise man remarks; and certainly with Roses there's a time to grow and a time to refrain from growing. Having had their early ardour quenched, let us hope that this season they will choose the latter better and more appropriate part for the next six weeks to come. Our prospects here are good; for though the too warm February sun in the early part of the month coaxed out a few little tender leaves on the points of the shoots, the latter half of the month has effectually compensated for this mistaken indulgence. Oh, north-east wind! I love you in February and March, but I dread you in May.

Certainly the rosery affords one great pleasure even in winter. How nice it is to walk round and "take stock"—to count over this row of Marie Baumann, to reckon up that line of Madame Rothschild! How often in imagination one clothes the leafless plants with glorious summer foliage and still more glorious flowers! How tenderly one bends over that puny representative of a new, and possibly a famous, name in time to come! Here is the batch of dwarfs on Manetti transplanted last November put-in in capital time, just before the heavy rain set in. How comfortable they look, carefully staked and liberally mulched. Observe, too, that the wood, which shrivelled slightly at first, is now fresh and plump to the very tips. Walk down the rows, how well they have moved! There is not a dead or sickly one among them. Now we come to the batch of dwarfs on seedling Briar stocks, strangers from Oxford; and well indeed they look, everyone apparently a man (or Rose) of might, ready to do, but I hope not to die.

Here are the standards: these have not been moved this season, and consequently look a little leafy at the end of the shoots, but nothing to hurt. Boreas has put that all to rights for us. Dr. Andry, Charles Lefebvre, Abel Grand, Alfred Colomb, La France—oh! as I read your names what visions rise before me! But now we will have a look at the stocks budded last summer.

The Briars, I grieve to say, did not take well, and display several blanks in the rows. The weather was very scorching when the buds were put in, and the ground dry. Seedling Briars better than I expected, but still not quite even. The buds remain quite dormant as yet. Dwarfs on Manetti a good take, hardly a bud failed. But—and there is a "but"—look down the rows, how many of the buds have begun already to shoo! Well, one cannot have everything. It is a good stock, easy to propagate, easy to bud, easy to cultivate when budded,

for it throws up hardly any suckers, but it certainly is a trifle too excitable.

Now for the Teas. Maréchal Niel, you are as usual too forward. Here is one climbing over the warm side of a poultry house covered with bloom buds already. Nice havoc there would have been had it not been sheltered with a few yards of unbleached calico. As it is there is no damage done, and we may look for some early blooms. Four or five plants of the same variety against a wooden fence facing south-east left unprotected are all cut. Climbing Devoniensis not quite so forward against walls and houses, very slightly frostbitten. Strong-growing Teas in open border look well. Madame Berard, where not moved last autumn, a little too forward. This is a good Rose. Moderate-growing Teas all alive and doing well. Now we will bid farewell to the garden.

But what is that little glass house in the corner there? Can we induce our steed to enter, or is his head too high? "That, sir, is our forcing house—small, it is true, for we are not rich, nor can we measure our glass by the thousand feet, neither have we a dozen gardeners at command; but, sir, we love Roses, and Roses we must have summer and winter if possible. Enter, and you shall enjoy vernal—yea, summer pleasures, though the paths outside are white with snow, and icicles dangle from the shoots. Behold the Maréchal clothing the back wall, and one of the sides laden with some two hundred buds, many of them just about to expand. See there pale Rubens smiling with modest joy in this haven of rest where no rude blast can enter. Here, too, is Catherine Mermet just unfolding its shelly petals; and here are Princess Mary of Cambridge, gentlest and most tractable of all Roses for forcing; Comtesse d'Oxford, Marie Baumann, Madame Rothschild, Achille Goned, Marguerite de St. Amand, Madame A. de Rougemont, and many others clothed in summer dress, and well set with buds."

Did you ever read what the veteran Rivers wrote with reference to the grafting of Roses? "What can be done," says he, "in the way of propagation in so small a house (12 feet by 8) with method is quite astonishing." And I may echo his words and say, "What can be done in the way of forcing both Roses and other flowering plants with a very small house is truly astonishing. You may, at all events, keep your greenhouse, or conservatory if you have one, always full of flowers, and cut a Rose if you are so minded every day of the year." —R. W. Beachey.

STRAWBERRY FORCING.

Strong healthy plants are necessary to success, and the way I have found to produce them may be acceptable. I do not concur in the plan of layering the runners on the ground where the plants are growing, for if it is a wet season they are apt to be choked by weeds and other runners, and must suffer root-mutilation by removal. If layered in their fruiting pots it is difficult to make the pots stand level, besides bruising the fruit in watering. Some prefer the plan of layering in small pots, using a peg or stone to keep the runners down, and urge that they derive support from the parent plant, which is about all the support they do get, for what moisture can such pots retain in a midsummer sun?

The best plan, in my opinion, is to procure in the latter part of June strong healthy runners free from red spider, cut them with about an inch of stalk before and after the runner, pot in thumb pots in light soil, place in a frame, giving them a good watering; shade with mats whenever the sun shines on them, syringe morning and evening, and keep them close, and with good management they will be ready to pot in a month. I use 6-inch pots and a compost of turfy loam with one-third rotten manure, no leaf soil being required. As soon as potted they are placed on ashes close together (as if a distance apart they only dry more) in a position partly shaded from the mid-day sun by distant trees. In the beginning of September they become too thick, and are removed to a more sunny position along the sides of walks running east and west. If worms are troublesome we use lime water. The pots are turned on their sides during heavy rains, but not put in frames till frosts occur, then the lights are always drawn off, excepting frost and rain.

The varieties are Keens' Seedling, which I find is still the best early kind; Viscomtesse Héricart de Thury, this is a good grower, very prolific, and of excellent flavour; and Sir Joseph Paxton, a variety that produces fruit of better shape in pots than outdoors, is very solid and of excellent flavour. Victoria (Trollope) is discarded, for it is of poor flavour, keeping but very little time after gathering, and a pale colour; the only point in its favour is heavy cropping, and is suitable for those who prefer quantity to quality. Keens' Seedling is grown in 48's. These are large enough for the earliest gatherings, the rest in 6-inch pots, which I consider are not too large. I never water with liquid manure until after the fruit is set. A moist atmosphere prevents red spider. Turf placed on shelves may be all very well for 48's, but with careful watering I think it is not required for larger pots.

Now a word or two as to outdoor cultivation. If the ground is trenched and manured heavily plants ought to remain in good condition for at least five years. The first season or two the crop may be heavier than subsequently, but they are not exhausted. Plant in September, so as to obtain a good start before winter, 2 feet 6 inches from row to row, and 2 feet in the rows. Old forced plants, as they are a season in advance, are preferable to young plants. Give a good coating of rotten manure in November after having given the ground a good Dutch hoeing to cleanse it of all weeds. Do not attempt to dig the manure in, for the heavy rains during winter will wash-in all the goodness, and digging would only destroy the roots. Before flowering give the ground a covering of clean litter. I do not use hay, as it may turn mouldy and destroy the fruit.—G. P., jun.

CALANTHES AT DRUMLANRIG.

Calanthes are grown to greater perfection at Drumlanrig than at any other place at which I have seen them tried. The principal varieties are C. vestita rubra, C. Veitchii, C. vestita lutea oculata, and C. vestita lutea flava. The second last named produces large pure white blooms, which are exquisitely pretty and afford a nice contrast with C. Veitchii. When I saw them last autumn they were nearly in full bloom; some were growing in 6-inch pots, and others were growing in those 4 inches larger. The bulbs in some of these were as large as a 3-inch pot, consequently a 10-inch pot did not contain a great number of them.

In pots of the last-named size I counted as many as sixteen and eighteen flower spikes, some of them being a yard long, and carrying from thirty to forty-five blooms each. The greater number of the flowers were open, a few only at the end of each spike not being fully expanded.

Your readers can form some idea of this marvellous sight when I say there were upwards of seven hundred open Calanthe blooms in a 10-inch pot; dozens of potfuls were in the same splendid order. Armfuls of them were used as cut flowers when the family were staying in the Castle, and when they went to Bowhill a large boxful was sent once a-week to them, and many decayed without ever being cut.

They are very valuable for vase and room decoration, as they keep fresh a long time in such a position. The mixture they are grown in at Drumlanrig consists of rough peat, silver sand, a sprinkling of loam, and a little sphagnum. When in full growth they are occasionally watered with manure water. They are rested after flowering, but not allowed to dry-off or starve at any season.—J. Muir.

LINUM TRIGYNUM AS A WINTER-BLOOMING PLANT.

This beautiful evergreen shrub is usually described as having been introduced from India in 1799 and as flowering in June. Don describes it as a greenhouse shrub which flowers in July. There is no doubt that this is the period of its blooming in its native habitat—the Adwaanee Mountains, and also as cultivated in the gardens around Cawnpore and Lucknow. Dr. Smith has, however, published a figure of it in his "Exotic Botany" for February, 1785, and informs us that it flowered in the stove of Mr. Greville at Paddington in the preceding December. It has therefore been known as a winter-blooming plant for nearly a century.

It is not often we see justice done to this fine old plant, it being generally found in a half-starved state in greenhouses, and producing a few straggling flowers towards the end of summer. That was evidently the case in the time of Don, and it is the case now; but it is worthy of better treatment, and, if this be accorded, it will give a reward by a profusion of its clean bright yellow flowers in the depth of winter. When in bloom the lower temperature of the conservatory or greenhouse appears to be in no way prejudicial to the plant, but during

the period of its growth it must have a more congenial atmosphere to bring it to perfection.

The plan I adopt with a fair amount of success is to secure healthy cuttings and strike them towards the end of March or in April. With a brisk heat they take root quickly and are potted in 3-inch pots, using a compost of good strong loam, manure, and sharp sand. The plants are pinched as soon as they become established, and the pinching is continued at every second or third joint: by this means a compact plant of agreeable shape is secured. They are shifted-on as required, and are eventually bloomed in 7 and 8-inch pots. They are grown on shelves in the stove or other position where they can have light and air, and are duly attended to by syringing and watering. Indeed they have just the same treatment in regard to temperature as the Poinsettias, and are grown with them all through the summer as the best scarlet and the best yellow winter-blooming plants we possess.

The pinching is continued until the end of September, and by this time they are compact bushy plants a foot in diameter and about the same in height. They literally cover themselves with their bright yellow flowers, and are dense balls of bloom for three or four months when the colour is particularly telling. They contrast admirably with Primulas and the usual flowering plants of the period, and are recommended to be more generally cultivated.

The main points of culture are to secure young plants every year, to grow in a warm genial temperature, to pinch frequently, syringe copiously, and give them strong rich soil. When the cultivator has done his duty the plants will do theirs, and will add a brightness to the houses which few, if any, plants of the period can surpass.

As the time is near for commencing preparations to secure a stock of this excellent winter plant, this short narrative of practice may not be inopportune to some of the many readers of the Journal, who, it is hoped, will no longer neglect to cultivate this too-much-neglected plant.—J. Christie.

ROYAL HORTICULTURAL SOCIETY.

March 17th.

The strength of the Exhibition undoubtedly lay in the groups of plants staged by nurserymen, of which the most prominent were the Camellias from Mr. Wm. Paul; the Hyacinths, and Cyclamens, and miscellaneous groups of Messrs. Veitch; and the mixed collections of Mr. B. S. Williams and Mr. Wills. Mr. Aldous also exhibited a small yet healthy collection of decorative plants. A group of Cyclamens from Mr. Goddard, gardener to H. Little, Esq., were very good, but of course not equal to the splendid plants in Classes 14 and 16 which received the first prizes for thirty and twelve plants respectively.

Class 3, Hyacinths. There were only two competitors, Mr. Douglas being first with bold spikes and good foliage; Mr. G. Toms, gardener to H. Wetenhall, Esq., The Poplars, Stoke Newington, being placed second. Amongst the best of Mr. Douglas's group were L'Innocence, pure white; King of the Blues, very intense; Von Schiller, red; Koh-i-noor, pink, General Havelock, dark blue, and Ada, buff; Grandeur à Merveille, waxy white; Laurens Koster, blue; Macaulay, Mimosa, Grand Lilas, and De Candolle. Mr. Douglas was the only exhibitor in class 5 for six new Hyacinths, and had the first prize for Diana, fine blue; Prince Imperial, blue, white eye; Alice, mauve; Oxford, very dark blue; Helen, pink; and Starlight, blue with white eye.

Class 7, for twelve pots of Tulips, there were also two entries, Mr. Douglas being more decidedly ahead of Mr. Toms than in the Hyacinths. Mr. Douglas's twelve comprised massive blooms of the following—Chrysolora, bright yellow; Vermillion Brilliant, Van der Neer, Proserpine (fine), Pottebakker, and Fabiola, all in duplicate.

Class 10, for six Orchids (nurserymen), Mr. Williams was the only exhibitor, and had Odontoglossum Alexandræ with a magnificent spike of sixteen perfect blooms; Cypripedium villosum, Cymbidium eburneum, Vanda suavis, Lycaste Skinneri, and the distinct Masdevallia Lindeni.

In Class 22, for eighteen hardy spring flowers in pots, the first prize was awarded to Mr. Dean, Ealing (the only exhibitor). They comprised well-bloomed pots of the following:—Lithospermum prostratum, Iris reticulata, Arabis albida var. præcox, Viola Victoria Regina, new bedding Pansy White Swan (a promising variety), Myosotis dissitiflora, Grape Hyacinths, double Daisy, white, red, and mauve Hepaticas, Aubrietia purpurea, Scilla bifolia alba, Saxifraga oppositifolia rosea, and Primroses Sulphurata, Single Mauve, and Crimson Queen.

Class 23, six hardy Primroses (acaulis type) double. Mr. Dean was again alone with Double Rose (bright), Double Crimson, very rich, and doubles Lilac, Sulphur, Primrose, and White. He was in the same position in Class 24, six single Primroses of the same type, and had excellently bloomed pots of Fairy Queen, Mauve Queen, Crimson Banner, Violacea, Rosy Morn, and Charmer; also in Class 25 for six plants of the Polyanthus type. The whole of these hardy flowers were very attractive, especially the single Primroses in Class 24.

Silver medals were awarded to the following collections:—Mr. Williams's group comprised a good plant of Adiantum gracillimum, Phalænopsis Schillerians, Abutilon Selowianum marmoratum, Amaryllis Mendeli (a grand variety), Æchmæa Mariæ-Reginæ, &c. Messrs. Veitch had small but beautifully-bloomed plants of Clematis in variety, chastely marked and telling Amaryllis, a basket of Rhododendron (præcox) Early Gem, lifted from the open ground the day previous, and full of flower; fine pots of Crocus, a glorious bank of Hyacinths, &c. Mr. Wills had highly attractive examples of Abutilon Selowianum marmoratum, Phyllanthus nivosus, and P. mimosæfolia, Ficus Parcelli, Crotons Weismani and majesticum, Terminalia elegans, Phyllarthron commorense, Panax excelsa, the distinct and interesting Xylophylla latifolia, Cupania undulata, &c. These plants were very clean and healthy. Mr. W. Paul's Camellias were medium-sized plants in perfect health, and exceedingly floriferous. Compacta alba, Alba plena, Jenny Lind, La Reine, Montironi vera, and Innocenza were amongst the best of the white varieties. Conspicuous amongst the reds were Leeana superba, Mathotiana, and Beali; and of the pinks Comtesse Woronzoff, Reine des Fleurs, Madame Lebois, Augustine superba, and Storyi were the best.

Bronze medals were awarded to Mr. Aldous for his miscellaneous group and to Mr. Goddard for his collection of Cyclamens.

Fruits.—In Class 28, for two bunches of late black Grapes, Mr. Ridout, gardener to W. S. Brown, Esq., Woodhatch Lodge, Reigate, was first with splendid Alicantes; Mr. Wildsmith, gardener to Viscount Eversley, second with excellently-finished Lady Downes'; and Mr. Donaldson, gardener to Lord Chesham, third with Alicante. (Four entries).

In Class 30, for three kinds of dessert Apples, Mr. Parsons, gardener to R. Attenborough, Esq., Fairlawn, was first with fine dishes of Blenheim Orange, Scarlet Nonpariel, and Ribston Pippin; the second prize going to Mr. Clark, gardener to Rev. A. D. Stacpoole, Writtle, Chelmsford. (Three entries).

In Class 31, for three kinds of kitchen Apples, Mr. Parsons, gardener to R. Attenborough, Esq., was first with fine specimens of Alfriston, Blenheim Orange, and Wellington (Dumelow's Seedling). Mr. Woodbridge, gardener to the Duke of Northumberland, having the second prize. (Four entries.)

In Class 32, for dessert Pears, Mr. Clarke was first with Ne Plus Meuria, Beurré Rance, and Knight's Monarch, also in the next class for kitchen Pears.

Vegetables.—In Class 35, for twelve crowns of Seakale, the first prize was awarded to Mr. Clarke, gardener to the Rev. A. D. Stacpoole. (One entry.)

Class 36, for twenty-four Mushrooms, Mr. Record had it all to himself with really splendid examples of high culture.

Class 38, for one brace of Cucumbers, the only entry was by Mr. Douglas with a beautiful brace of his Tender and True, which is evidently a variety of the highest excellence.

Fruit Committee.—Henry Webb, Esq., in the chair. Mr. Clark, gardener, The Vicarage, Writtle, Essex, sent fruit of an Apple said to be Gravenstein, but which proved to be Reinette Bauman. Mr. Bennett, the Gardens, Hatfield, sent a dish of Lowndes' Pippin, a tender-fleshed brisk Apple. He also sent a dish of Uvedale's St. Germain Pears, to which a letter of thanks was awarded. Mr. Monro of Potter's Bar sent a box of Duke of Edinburgh Cucumber containing a dozen fruit, which were much admired, and to which a cultural commendation was awarded, it having already received a first-class certificate. The plants were planted on the 9th of January, and the first fruit cut on the 8th of February. They were grown without bottom heat.

Floral Committee.—R. B. Postans, Esq., in the chair. A first-class certificate was awarded to Mr. H. Bennett, Salisbury, for Rose Hippolyte Jamain. Votes of thanks were given to Mr. R. Dean for a basket of Primroses; to Messrs. Paul & Son, Cheshunt, for two boxes of cut Roses; and to Mr. E. Bennett, gardener to the Marquis of Salisbury, for a spike of Hedychium Gardnerianum; and cultural certificates to Mr. W. Wilson, gardener to — Adams, Esq., for Cattleya Amethystiglossa, and to Mr. W. Shorten for four Cyclamens.

Lily of the Valley—Fly Orchis.—In a wood at Roudsea near to Holker Hall, Lancashire, the seat of his Grace the Duke of Devonshire, the Lily of the Valley grows most luxuriantly, and year by year many thousand roots and hundreds of large bunches of the flowers are brought away by the neigh-

bouring inhabitants, who make the wood a favourite day's resort at the season when the Lily is in bloom. The supply seems to be endless, and if growers would only study the nature of the Lily no fear need be entertained of reproducing the plant year after year.

I find that by placing a number of roots in any useless corner of the garden under trees I can have an unlimited supply. At the present time I have a vast bed in a place where no other flower will grow, and which bed has been there for fifteen years.

In the wood above mentioned we come occasionally upon what is locally known as the Fly Orchid (Ophrys muscifera or Twayblade). It more closely resembles a fly having alighted on a green blade than anything I have ever seen under house cultivation; but despite all efforts I have made, I have been unable to grow them. Can any of your readers assist me with this information?—Beta, *Ulverston.*

OUR BORDER FLOWERS—MASTERWORTS.

This is a small family of border plants of no very striking character, yet interesting as affording variety. I am not aware that we have a native species in this group, yet I believe that Astrantia major is considered by some to be naturalised in our climate. Most of the kinds we have in cultivation are from the Caucasus. They require no particular treatment, but will flourish in moderately good garden soil. They are moisture-loving plants, but should not be saturated with water.

Astrantia maxima and A. major are well adapted for shady places in what is termed a wilderness or open spaces in the shade of trees. Astrantia pauciflora and A. minor are worthy of a place in the herbaceous border. A. carniolica is the most interesting of the family, and is worthy of careful attention; it thrives well in a soil composed of good sound loam, leaf mould, with a little sand all mixed well together, and to be attended to with water. Their star-like flowers make them desirable where cut flowers are in request. They continue in bloom for a length of time, and are easily increased by division either in spring or autumn.

DONDIA EPIPACTIS.

Many of our early spring flowers are now appearing above ground, and will soon reward us for our care of them with their cheerful presence and varied forms. A little diminutive plant seldom met with is beginning to put in an appearance—viz., Dondia Epipactis. It is sometimes called Astrantia Epipactis and Hacquetia Epipactis, and these synonymes are often not a little puzzling to the uninitiated.

To see this little gem to perfection it should be grown in pots in a compost of sandy loam, peat, leaf mould, a little sand, with some broken sandstone in a rough state all mixed together. It requires good drainage, and a rather shaded situation will suit it exactly. It should on no account be suffered to become dry when well established. When grown in a 6-inch pot the surface of the soil should be covered with pebbles or spar, and when the little disk-like flowers and leaves appear through them they have a very pleasing effect.

I have seen plants do well in a peat border and on a rockery, and they may also be kept plunged among alpines or placed in a cool fernery. This plant is increased by division after it has completed its growth. Time, patience and care are required to work up a stock. When well established they last for a considerable time. Being of diminutive stature and unable to endure rough handling, I fear that its cultivation will still continue to be neglected.—Veritas.

MRS. PINCE'S GRAPE.

I can endorse the opinion of your correspondent Mr. Harrison Weir (see page 158) as regards the quality of this fine Grape, which we find here to be the best flavoured of all the late-keeping sorts. The last bunches are now being used, although to all appearance they would keep good for at least another month, as not a single berry is decayed. In some instances, however, the jet-black colour of the fruit has given place to a foxy red, but without the slightest deterioration of flavour.

I should, however, be sorry to follow the example of your correspondent in pulling up all the Lady Downes' variety. We have here a house devoted to the two varieties above named planted rod for rod, and for late keeping both are found to be excellent. Another house of like dimensions is planted with West's Black St. Peter's and Black Alicante, and these sorts, although they are doing as well as could be desired, the fruit is nevertheless greatly inferior to that of Lady Downes' and Mrs. Pince. I should not recommend the extensive planting of either West's Black St. Peter's or Alicante; the former, although a very good variety, is too thin-skinned to hang late in the season, while the skin of the Alicante becomes of a very tough leathery texture, and is very deficient in flavour. Lady Downes' seldom shrivels, and retains its pleasantly piquant flavour to the last; but Mrs. Pince is certainly the best flavoured of all the late-keeping sorts that I am acquainted with.—P. Grieve, *Culford.*

NOTES FROM MY GARDEN IN 1874.

GREENHOUSE.

In my small way I have not—indeed, cannot have—much to record that will interest others; but as I have oftentimes found that I was glad of hints which others might have hardly thought worth giving, it may be that even these trifling matters may help some amateur who keeps his little boat close to shore, as I am obliged to do.

Camellias, then, were, let me say, a failure with me, save in the case of one or two plants, and this I attribute to my having placed them out of doors in summer—a plan, I am aware, often recommended, but one which requires great caution; for if either the pots are so placed that worms can get into them, or watering is neglected, it is fatal to the blossoming: the buds are developed to a certain size, and then they gradually become brown and drop off, and this latter is often the case when there is dripping weather in the autumn. The surface of the pots looks moist and the foliage fresh and green, and one is deceived as to the real state of the balls and roots. My general plan is to leave the few I have in the lower house under the shade of the Vines during the summer, and then move them into the upper house for the winter and spring; but last year I did not do so, and hence to a great extent the cause of my failure. There are some kinds, such as Duchesse de Berri and Mrs. Abby Wilder, which I find drop the buds more readily than others; while some of the most satisfactory I find to be Sarah Frost, Mathotiana, Jubilee, Mrs. Cope, Elegans, Chandleri, and Imbricata. The old Alba plena, one of the very best whites, I find also very liable to drop its buds.

Azaleas, on the other hand, were quite a success; indeed they are, with a little care, the easiest grown of all plants, and for a stage of bloom there is nothing to equal them.

Strawberries were also a great success, and I find nothing better than Dr. Hogg suit my purpose. A friend has told me that, instead of top-dressing the pots when they are placed on the shelf with old hotbed stuff, I should do better to use nearly fresh cow manure, and I am going to try it this season.

I have discarded Primula japonica from the house, and given it a place in the open border. It is doubtless very showy, but to grow it well it takes up a great deal of room and does not afford blooms for cutting, and I therefore prefer giving the room to other things.

I have introduced a few good-sized plants of Arum, for I am very fond of their large white blooms. One of them placed in a tall vase, with a sprig or two of scarlet Geranium and a bit of foliage, looks exceedingly well.

Of show Pelargoniums, thanks to my friend Mr. Turner, I had a capital display filling one side of my house; and the following is my judgment of the new varieties sent out by him in 1874, at least such of them as I have grown.

Blue Boy.—A purplish flower; the top petals of deep colour with a narrow margin, and with a good deal of novelty about it.

Countess.—A very grand flower of fine substance; lower petals salmon pink; maroon spot on upper petals, white centre. Very good.

Chieftain.—A nice, but not first-class flower.

Duke of Cambridge.—I think the finest variety of the season; bright scarlet, medium black blotch on top petals; free-flowering, smooth bright variety. Very brilliant and fine flower, and quite an acquisition.

Duchess.—Rich crimson flower; black top petals, narrow edge, white centre. Somewhat delicate in growth.

Druid.—Lower petals rosy lilac, maroon spot on top petals. Very dwarf habit.

Flora.—Lower petals rosy purple. Dwarf and free-flowering, but not a first-rate flower.

Giant.—Lower petals bright pink, maroon spot on top petals. Very large, but in form not equal to some others.

Protector.—A fine flower; top petals maroon, with lilac margin; fine shape.

Prince of Wales.—Large flower, habit good; lower petals rosy purple; top petals maroon, white centre.

Ruth.—Cherry rose, new in colour; small spot on top petals, white centre. A nice pleasing flower.

Senator.—A mottled purple flower of medium quality.

Statesman.—Lower petals rich crimson, richly shaded; top petals black with crimson edge.

Scottish Chieftain.—Lower petals richly painted crimson; top petals dark maroon, with a narrow fiery margin. A good flower.

Topsy.—Dark flower, of medium quality.

The few Roses that I had in pots bloomed nicely and are looking fairly well again this season; and amongst the plants I had for my later blooming were some very nice Lilies. L. Humboldti is a very pleasing and fine-looking flower, and L. Leichtlini is exceedingly pretty. I did not succeed in blooming Washingtonianum, but I saw it very fine with Mr. Backhouse of York, and am hoping to bloom it and others this season.

I have said my say about my little house, and I think that, although I cannot pretend to any great cultural skill, I manage to have as much enjoyment out of my small house as most people do; and some of my friends are fain to confess that they wonder how I manage it. It is but another illustration of the old adage, "Where there's a will there's a way."—D., *Deal.*

NOVELTIES IN THE ROYAL GARDENS, KEW

In the temperate house a magnificent tree of Acacia dealbata is beautifully in flower. Though it cannot well come under the above title, it is still worth mention. It is more than 30 feet high, and laden on every branch; the leaves are glaucous and very Fern-like, forming with the inflorescence of delicate small yellow balls of flowers a very elegant object. These are produced in long racemes or in panicles with a few racemose branches, all bending in the most graceful manner. In addition to the decorative value as a specimen its branches are useful for cutting, either to stand alone in a small vase or to form the basis of an arrangement in which it stands the chief object. The leaves unfortunately fold in sleep at night.

For high conservatories the best of the strong-growing Acacias should be considered indispensable. After giving form to the specimen by cutting back, the aim of the cultivator should be to promote free growth, when flowers will be produced in proportion, provided of course that the tree has reached a sufficient maturity. Cuttings may be rooted, but perhaps the best way is to raise from seed, sowing about this time. The young plants will soon become vigorous, and so long as sufficiently small will be of value for the foliage to arrange with flowering plants, and may also be used in the same way as A. lophantha for subtropical combinations. A. dealbata and a few other species are cut down largely in the Australian colonies for the sake of the bark, which contains tannin. So far has this been carried that the trees have nearly disappeared.

Toxicophlæa Thunbergi is flowering in the Palm house. It is a beautiful shrub with opposite dark green coriaceous leaves and pure white sweetly-scented flowers. They are produced in Ixora-like clusters in the axils of nearly all the leaves of the young growth. The branches are slender, with foliage and flowers closely arranged, ready at once to form a wreath. It is rare, and plants elsewhere have probably been had from the Royal Gardens. At the Cape it is known to colonists as the Gift Boom or Poison Tree, and a decoction was formerly used by the natives for poisoning their arrows.

A plant very closely allied was sent out by Mr. B. S. Williams about three years ago; it has been called T. spectabilis. Another species is cultivated under that name, but is apparently quite distinct, and of less horticultural value.

Culford.—Mr. Douglas has made a slight mistake at page 165 in his notes of Culford, as he says, "Of bedding Pelargoniums the best white-flowered variety is a hybrid raised at Culford named Dolly Varden; it is a cross between a bronze Zonal and P. peltatum elegans." Now, the flowers of this variety are not white, but are of a dark magenta colour; and what we consider as our best white bedding sort is Bridal Wreath, a hybrid Ivy-leaved sort, but which was not raised here. Fig. 43 is represented as the "Conservatory and Flower Garden," it should be the "Garden Cottage, with Flower Garden in Front." The conservatory, with small garden and fountain in front of it, is near to the Hall.—P. Grieve.

CHIMONANTHUS FRAGRANS.

This is a most valuable winter-flowering deciduous shrub or wall plant. It comes into flower just at a time when every sprig of bloom is welcome, and especially those which possess a delicious fragrance. In this respect this plant is invaluable, for its odour is delightful. We have had a supply of bloom twice a-week from the first week in December until the present time. The blossoms should be plucked off and placed in glass or other small dishes; small sprigs of evergreen shrubs mixed with them add to the appearance. Being so hardy and so easy of cultivation one is surprised at not meeting with it more generally in our gardens. It should be invariably planted in villa gardens, many of which have not the convenience of glass to force other fragrant flowers which require protection from frost and snow. It can be had of any nurserymen. If planted in a south aspect, no matter whether against a wall or rustic summer house, in the month of April in good garden soil it will make rapid growth. At the end of June the leading shoots should be carefully trained, the remaining shoots should be pinched back, leaving six or eight eyes; by leaving them long a much longer supply of bloom is secured. Nothing more is required to be done until after the blossoms are all taken off, when the leading shoots should be secured and the remaining laterals pruned back to one eye.—Joseph Peirce.

GLASNEVIN GARDENS, DUBLIN.

The following is a list of shrubs and flowers in bloom in the open air at Glasnevin Botanic Gardens:—

Anemone stellata
Arbutus tomentosa
  Unedo
Arabis alpina
  auriculata
Armeria cephalotes
Aubrietia albida
  caucasica
  græca
  grandiflora
  hesperidifolia
Bulbocodium vernum
Camomile
Cardamine rotondifolia
Clematis calycina
Coronilla glauca
Crocus susiana and others
Cytisus Alshingeri
Doronicum Columnæ
Draba altaica
  rupestris
Epimedium colchicum
Erica arborea
  herbacea
  mediterranea
Erythronium dens-canis
Forsythia suspensa
  viridissima
Gorse
Hepatica angulosa and others
Helleborus atrorubens
  angustifolius
  abchasicus
  cyclophyllus
  guttatus
Helleborus graveolens
  intermedius
  niger
  odorus
  olympicus
  orientalis
  purpureus
  kamtschaticus
Iris reticulata
  stylosa
Laurustinus in varieties
Leucojum vernum
Polyanthus
Primula macrocalyx
  marginata
  Palinuri
  Double Yellow
  Double Purple
  Double White
Pyrus japonica
Pulmonaria sibirica
Saxifraga cæspitosa
  crassifolia
  hispida
  oppositifolia alba
  retusa
Scilla bifolia
  bifolia alba
  sibirica
Sisyrinchium album
Triteleia uniflora
Viola reniformo
  Double Purple
Wallflower

—P. N. W., *Glasnevin, Dublin.*

NOTES RELATIVE TO THE POTATO.

"Beta's" argument is evidently based upon a misconception, and the point at issue just hinges upon the uncertain opinion of what is a poor soil and what is a rich one. He evidently agrees with me that mere opinion is of very little value, and if any good is to be gained from a discussion, general results—not of a single season, but of several—must form our basis. In proof of this we have only to refer to "Beta's" statement that in a district on the north-west coast, where "the rainfall is the greatest in England," and the disease is usually so virulent that the Fluke is "wore out" by it, yet the Potato crop of last year was "the soundest in the United Kingdom." The fact is interesting, but is of no particular value, and only serves to prove the truth of another well-known fact—that a hot dry season is favourable to Potato culture in a wet district.

There is a great difference in a poor soil enriched by heavy dressings of fat manure and an alluvial deposit requiring none

at all. Alluvial soils are the most fertile of all natural deposits. They contain portions of everything that is washed by the waters by which they are formed. Clay, silica, lime, humus, and a variety of fine gritty substances are intimately blended together, abounding in nutriment, and admirably adapted for Potato culture. If the disease was really caused by the use of rich farmyard manure, surely those grown in such a soil as the above would be perfectly sound. The fact that they are not so affords conclusive evidence that "Beta's" deductions are worthless. It is true that rich manure induces a rank plethoric habit in the haulm, and it is then liable to suffer from disease in a much greater degree than in its normal state. The farmers hereabouts manure their land for Potatoes at the rate of forty cartloads per acre. I have used double the quantity, and had no blight till the August rain set in. Let "Beta" keep to his poor soil and small Potatoes if they content him. I, too, have to deal with a poor soil—so poor that the very weeds will hardly grow upon some portions of it; but I will use all the manure I can, and care nothing for the blight if I can have the crop housed before the late summer rains begin.

Your correspondent is by no means singular in his impression that manure is the cause of disease. It is an old idea to which some persons cling with surprising persistency. It was only a few months ago that I received a copy of an essay, the special object of which was to prove this, and the writer's remedy was actually to burn the manure and apply the ashes to the land!

Three or four years ago some land was taken in hand for Potato culture, which for many years had been so neglected that it was quite innocent of manure. It was a light sandy soil, and so miserably poor that there were very few weeds upon it, although it had been stirred by a plough a few months previously. I was unable to manure the whole of it, and so by way of experiment a few perches of the unmanured portion was trenched and planted with Potatoes. The stock was procured from a leading wholesale firm, who stated that the seed was not only untainted, but that it was absolutely blightproof. Now mark the result. The crop from these Potatoes was very much diseased, while those in the land which was manured at the rate of half a cartload to the perch were almost free from blight!—Edward Luckhurst.

MEALY BUG.

I can confirm what Mr. Pearson says on the impossibility of thoroughly eradicating this king of pests. I have recently attempted to clean two plants much infested with it. Gishurst was applied 2 ozs. to the gallon, then 4, and lastly 6 ozs.; but though apparently got rid of, the pest appeared again, of course from the eggs in the wood, which the compound did not destroy. The injury done to the foliage of one Ixora by so strong a dose is most apparent, and the appearance of the specimen is bad and unpleasant.

I am glad, of course, to say that I have very little mealy bug, though in a large collection of plants like mine I believe it would be impossible to be absolutely without it, and the rapidity with which it increases makes it a most formidable foe. I hate the sight of it. I am equally careful with Mr. Pearson in examining plants from nurseries, but it not unfrequently happens that they are superficially cleaned before being sent away, and thus the eye is deceived. In a few days—almost hours I might say—out comes the pest, and you wonder where it could possibly have lurked. I daily pick all off with the hand that I can see, using a fine but blunt instrument; and one of my gardeners used to say he believed I could smell them, as they never escaped my notice. If I received a plant badly infested I should either destroy it immediately or return it to the sender. To keep the insect down daily vigilance is absolutely necessary; no occasional measures will suffice, and now is the time to be specially active and watchful.—T. M. Shuttleworth, F.R.H.S.

A very cheap and effective remedy for the destruction of the mealy bug is petroleum. I have used it with success on Gardenias, Stephanotis, and other softwooded plants, and have found it instantaneous in its effect, producing sudden death. It has the advantages of being cheap, easy of application, and clean, for being almost colourless and of a volatile nature no traces remain of its application. I have never found any plant on which it has been used any the worse for its application.

Will you let me know if it is an unusual circumstance for a pink Primula to have a white flower on the same stem as the pink ones? I have one now in bloom in my greenhouse. Charles Hart.

[The diverse colours of the flowers on your Primula are unusual. You will have seen our note on the flower you exhibited at the Royal Horticultural Society's Floral Committee.—Eds.]

TRADESCANTIA VIRGINICA.

This is one of the Spiderwort family of plants, and belongs to the natural order of Commelynaceæ. The genus was named in honour of Tradescant, who was gardener to Charles I. The variety figured belongs to the hardy herbaceous section, and was introduced from North America in 1629. It is not only one of the best of its class, but in colour is one of the richest of all flowers. The colour is a bright intense blue, worthy to be compared to that of the beautiful stove plant Tillandsia Lindeni, and is set off to advantage by its small bright yellow stamens. The plant grows to a height of 1½ foot, and is compact and dense, requiring no sticks to support it. It delights in a deep rich soil, and enjoys copious supplies of water in the growing season, but a stagnant soil is injurious to the root during winter. It is an excellent border flower, and should have a place in all collections of hardy plants. It commences to bloom in July, and continues until late in the autumn. In mild winters it is evergreen, but severe frost kills the foliage. This, however, does no harm, as it is certain to push up as vigorously as ever in the early days of spring. It is admirable for cutting from the blooms lasting well in water, and its charming colour is always admired. It is increased by root-division, and than the present month no time is more suitable for increasing the stock or procuring a supply of roots. These must be kept moist during the process of removal.—W.

Fig. 53.—Tradescantia virginica.

HEALING WOUNDED LEAVES.

The following facts may be interesting to some of your readers. I have a fine plant of Amaryllis, some of the leaves of which were accidentally split nearly across the whole width. Knowing the importance of leaves to the development of the bulb I was unwilling to cut the wounded leaves off, and I applied some Friar's balsam on both sides of them, held the broken edges firmly together by means of little bits of cotton wool and slips of paper, and supported the leaves with sticks

and list. In the course of a fortnight the fractures were entirely healed, the leaves self-supporting, and there are now only slight scars remaining not the eighth of the length of the original wounds.—E. E. P., *Richmond, Surrey.*

[Our readers will smile when they first read of applying Friar's balsam to a wounded leaf, but the application is justified by frequent practice. There is not, probably, any more healing power in the Friar's balsam than in gum water; any such application excluding the air and preventing the lips of the wound drying would be effectual. The sooner the wound is closed the more certain the healing.—Eds.]

ROYAL HORTICULTURAL SOCIETY.

To those who attended the adjourned meeting on Tuesday the 9th inst. it must be well known that at an early stage of the proceedings I was about to make a few observations, but the Chairman ruled that a gentleman rising at the same time as I did had the precedence. The remarks I desired to make had no reference to the report, and therefore after the amendment was proposed and seconded thought I should be out of place in intruding my general remarks on the meeting: hence my now writing.

It has been observed, both outside the Royal Horticultural Society and in, that the professional horticulturists take but little prominent part in the Society's annual meetings, that their voices are seldom heard in the discussions, and therefore they have been treated as nonentities and as unworthy of any consideration: I judged, therefore, it was necessary for some one of them to explain their position and set the case right to the Fellows generally.

There are various reasons for the reticence and seeming apathy of the professional horticulturists at the Royal Horticultural Society's meetings. They as a body, from their studious avocation, are somewhat diffident; their opinions are seldom or never asked except in a secondary way, and hence the small action they have prominently taken; and some of them feel—I among the number—that they could not spare the time to always take an active part in the Society's affairs, but those that could not do so would zealously support their colleagues.

When alluded to, however, it must be apparent that horticulturists cannot possibly take any zealous interest in the Royal Horticultural Society constructed as it is at present, for it is a Society formed for a technical object, but with a Council elected for carrying on its work with few exceptions composed of gentlemen almost entirely devoid of the necessary technical knowledge for that purpose. But what would be thought of the Royal Medical Society if it had no doctor on its Council? Would the Linnean Society of London be looked up to with the respect it is by scientific men throughout the world if its managing members had not a profound knowledge of botany and zoology? Would the Architects' Association carry on its work for any good purpose if no architects were on its board? In what an anomalous position, then, is the Council of the Royal Horticultural Society without a single professional horticulturist belonging to it?

I know all the objections that can be urged against this. It has been said that the Council of the Society could not be composed of gardeners. Possibly not: but there are gardeners and gardeners, and I am afraid the professional horticulturists would be found lacking much of the technical knowledge that a gardener requires. However that may be, there have been eminent men who have not been ashamed to be called gardeners. The professional horticulturist, however, is only a gardener somewhat in the sense that an architect is a carpenter or mason.

Again, it has been urged that if professional men were on the Council of the Royal Horticultural Society it would be swayed by trade influences. But has anyone ever heard such an argument against the Chemical Society because chemists direct its affairs? or, indeed, can such be alleged against other societies because professional and business men take an active part in their administration? It has also been stated that it is of the utmost importance, considering the state of the Society's affairs, that good financiers should be on the Council rather than horticulturists; but I have yet to learn that the latter are wanting in this respect. The yearly expenditure or monetary transactions of the Royal Horticultural Society are as nothing compared to those of the best horticulturists, which are generally guided to a successful issue.

The many failures in the Society's affairs are owing in a great measure to one great fundamental cause, and that is that the Society has never, since I can remember, had a thoroughly practical horticultural council—a council in which the horticulturists throughout the United Kingdom, both professional and amateur, could have perfect confidence. If it had I have little hesitation in saying that instead of four thousand it would have nearer forty thousand Fellows, and not by reducing the subscription, as a member of the late Council has proposed, for now there is a two-guinea fellowship.

Alluding to a member of the late Council reminds me that it did good horticultural work by establishing the provincial exhibitions. These, however, have fallen through, as I believe they also would if they had been carried on by the late Council, for the simple reason that if the Royal Horticultural Society of London is desired in the provinces it is not because of its name, it is not in consequence of men of great social influence being on its Council—for in any district there are county families; but what is desired is to hold communion with, to make the personal acquaintance of, and to fraternise with men whose names are known, not alone at Kensington but throughout the horticultural world, for their technical knowledge and their practical experience, and there were only one or two such on the late Council.

With fair management and with such a Council as I have suggested I have no doubt an annual profit of from £1000 to £2000 would be made from the provincial exhibition, and this besides doing legitimate horticultural work, enlisting the sympathy, and making a large number of Fellows in the districts which were visited. But I venture to say, and I do so with some regret—still it is necessary to be candid, although I should be sorry to wound the feelings of the Council—that beyond a few their names would not be known in connection with horticulture outside the Horticultural Society. What an anomalous position, then, horticulture in London is in. If it were necessary for the Society to send a deputation on any horticultural matter abroad, beyond one or two their names would not even be known.

Fortunately, however, horticulture does not depend on any society, the love of it increases with the higher development of civilisation; still professional horticulturists cannot but deplore the present state of what should be the first horticultural society, not in England alone, but in the world. And this brings me to the consideration of the Horticultural Gardens, for about these I differ somewhat from my colleagues.

They are leased on such easy terms that I am not one of those who advocate giving them up; for whatever may be said against these gardens, I consider them a monument of horticultural skill as a town garden, and from what I have seen I much doubt if they are to be equalled in any capital in Europe. The rent need only be paid once in five years—something, therefore, under £500 a-year for those magnificent ornamental grounds. I know it is stated that £500 a-year cannot be set aside to defray the rent; that £2400 must be paid in one year, and that every fifth year; and here again crops-up the want of a truly practical horticultural council, for various ways would then suggest themselves of easily providing the rent. A plan occurs to me at this moment—viz., to hold a grand international horticultural exhibition every five years. I doubt not the horticultural Fellows would provide a guarantee fund, and if not, I believe the professional horticulturists would subscribe it themselves. But work such as this would involve could scarcely be expected from amateurs, much less from those who are not horticulturists. Amateurs may render good advice and service, but in practical work and technical knowledge they can seldom be expected to take the place of the professional man. If any one had a sick child they would scarcely send for their amateur friend who has always a favourite pill to prescribe or some essence to recommend, but would rather send for the man of professional skill, in whose practical knowledge the utmost reliance could be placed. The Horticultural Society is now that sick child, and the inference is obvious.

If the primary object of the Horticultural Society is to be merely the keeping of the gardens at Kensington as a London square, then good horticultural work is not of paramount importance, and it matters but little how the Council is constructed; but if the legitimate objects for which the Society was founded are to be carried out, it behoves the Fellows to take action and see that a good Council of the best professional and amateur horticulturists are guiding it.

As an instance of what practical horticulturists can do, I may mention that previous to 1865 we at different times had been receiving invitations from our foreign friends to international entertainments, we had accepted of their hospitality

which was given with no ungrudging hand. The English horticulturists felt they must do something in return, and like Britons they were determined it should be well done, so they projected an International Horticultural Exhibition. They applied to the Royal Horticultural Society, but then, as now, their Council was too technically weak to do anything in the matter. The horticulturists, not to be beaten, then did it themselves at an expense of something like £20,000 (that magnificent Exhibition will still be in the recollection of many of your readers). As the time neared for closing that Exhibition it was found there would be a deficit of some thousands of pounds. Here, again, the practical element rose to the surface; the Committee held a conference, and decided they would not call on the guarantors that had given it their confidence, but that they would continue the Exhibition a few days longer. This was an easy matter, for several on the Council were large exhibitors, and the other exhibitors were their friends. In the end, instead of a financial failure it was a success, so much so that the Committee actually had a surplus of £2000, which they scarcely knew what to do with. They gave £1000 to the Gardeners' Benevolent Institution, and bought the Lindley Library, which they presented to the Royal Horticultural Society, otherwise to this day there would not be so much as a library belonging to the Society.

I cannot pass from this subject without paying a tribute to the excellent generalship of Lord Bury. I have sat at the anniversary meetings of many societies, but I have never seen a president who could meet great difficulties and smooth over extremely perplexing circumstances as easily as his lordship.

At the last meeting of the Horticultural Society one or two gentlemen incidentally mentioned that they belonged to three or four learned societies. When the observation was made (for I also belong to eight or ten) it occurred to me how different they must consider the annual meetings of the Royal Horticultural Society to those of other societies, when it is usual for the president or some member of the council to give a short retrospect of the important events of the year, with glimpses of what are likely to occur in the future, and some of the Fellows of the Royal Horticultural Society would have been glad to have heard from the President what part the Society took in that great assemblage of botanists and horticulturists at Florence last year; what they intend to do this year at the International Exhibitions at Cologne and Antwerp; as also what they purpose to do next year in Philadelphia.

What can be thought of the arrangements for the flower shows at Kensington this season? The Committee issued a schedule announcing what shows would be held, detailing the objects for which prizes would be offered. They then advertised that four of those shows would not take place; but at the last meeting announced that they would all be held, but that exhibitors would be asked to take 50 per cent. less than the prize money that had been offered. Can vacillation go further than this?—William Bull.

[We have received from Mr. Cuthush, just at the eve of going to press, a letter controverting a somewhat generally accepted idea—that the principal exhibitors had been consulted in the matter of the postponement of shows. His firm had not been consulted, but received a special communication that the spring show was abandoned, and as a consequence his Hyacinths were retarded to form a show at Highgate in Easter week.]

THE PREPARATION OF FORCED FLOWERS.

We have many beautiful hardy flowering shrubs which are gratifying to the eye and grateful by their fragrance. We have the Kalmias, hardy Azaleas, Lilacs, Rhododendrons, and a host of things too numerous for me to think of at this moment; but I suppose the prevailing idea with too many people is, that because a plant or shrub is hardy it will stand any amount of rough treatment with impunity.

With respect to hardy shrubs I can give convincing proofs of the good results of the treatment I so strongly recommend, and facts, being stubborn things, will speak for themselves. I have now (February 18th) two nice bushy plants of Rhododendrons in full bloom. They are in 10-inch pots, and would be no disgrace to an exhibition tent. One plant has over thirty well-developed trusses of bloom on it, the other not quite so many, but still good. Now, in making this statement, it is not with an idea to cause a sensation and advance something unheard of; that is not my motive, as there are many equally good plants in the country at this moment. In mentioning these plants my main object is to remark that they are not forced, but their early blooming is simply the result of last year's treatment; neither are they early-forcing kinds, but such as would in an ordinary way bloom in April and May. Last year they were moved to a late vinery after blooming; there they made their growth and set their bloom buds. After this they were turned out of doors, and plunged up to their rims in the borders, so as to save watering, and when the winter frosts set in they were packed closely together with other things, and the pots covered with Brakes (Fern). There they stood the ordeal of 30° of frost, yet, notwithstanding, they were in January actually bursting their bloom buds and showing colour. They were then placed, not in the forcing house but in a cool vinery, to open their blooms.

The line I have marked out for one or two things is equally applicable to many others. Deutzias come under the same treatment as the foregoing; and in reading Mr. Dodgson's cultural remarks I made a pause when I read the words "when they have done blooming turn them out of doors to make their growth." It is the turning-out question from which I must dissent. Yet I would not be dogmatic and say that they will not bloom under such treatment; but I feel that it is against the natural order of things to enforce that mode of culture. I am fully convinced that growing them, and, to a certain extent, ripening their wood under glass, is the royal road to success. By that treatment they will give us quick returns the following season with a minimum amount of fire heat, and will pay us back with interest for the reasonable care bestowed on them after blooming.

This is simply an outline of practice and experience on a detail in the culture of forced shrubs, which I sometimes think is not so generally adopted as it should be. On this point, however, there may be a divergence of opinion; but on this I have only to say that a kindly-expressed difference with the sole object of eliciting truth is what we should all aim at, and at all times endeavour to make the person subservient to the subject. Now that the blooming period of forced shrubs will soon be over I ask that the plants have reasonable care, and by making their growth and forming their buds early under glass they will unfold their blooms proportionately early another year, and this with the least amount of forcing. Does not this suggest, that by simple and proper preparation of the plants, many who do not possess highly heated structures may yet have hardy shrubs blooming in their vineries or greenhouses during the earliest months of the year?—G. R. Allis.

BOILER FOR HORTICULTURAL USES.

About two years ago I had a cast-iron saddle boiler, which was a good boiler of that class, but, like all other common saddle boilers, there was great waste of fuel. As I was erecting more houses and adding more piping I required a larger boiler, and fixed upon one on the coil principle. In fact I bought two, and had them fixed so as to work jointly or separately at will, which with me proved a failure; and last November I had them removed and replaced with one on the saddle principle, having a water-way back with two intermediate flues. The hot air is made to pass underneath these flues to the back of the boiler, up the back, and over the top as in the common saddle.

I have a boiler now heating 1400 feet of piping—viz., hard forcing with about two-thirds the amount of fuel, and instead of having to remove every other day a barrowful of ashes to be used by other boilers (which in the coil boilers could not be used up), this is all consumed. This boiler is quite capable of heating 2000 feet of 4-inch piping. If my memory serve me right this was about the second boiler cast and offered to the public on this principle. It is cast in sections and bolted together by strong iron rods, so that if in case more piping is required one or more sections can be added with little trouble. It is made by Boulton & Paul, Norwich. I like it so much that I intend removing another saddle boiler to make room for one like it. Anyone in want of a boiler would do well to see this in full use.—T. Harwood, *Market Gardens, Attleborough.*

THE BEECH (Fagus sylvatica).

There is no reasonable doubt of the Beech being the Fagus of the Romans. Pliny says that this bore the sweetest of mast, that it was a nut enclosed in a three-angled rind, that hogs delighted in the mast, and that the pork they formed was especially wholesome. The fruit of no other European tree than that of our Beech agrees with those particulars. It

has been concluded that the Beech is not a native of England, because Cæsar in his "Commentaries" states that "timber of every kind, the same as in Gaul, except the Beech and Fir," are in Britain. If he had prefixed to that sentence "I saw," he would have truly recorded the extent of his knowledge; but he was not justified in writing so comprehensively, inasmuch as that he never penetrated into what are now our midland counties, and only into a very small portion of our seabord. He never advanced as far as that district which the Romans' successors—the Anglo-Saxons—named Buckingham, which, using Camden's words, "is given to bring forth Beech trees plentifully, which the English Saxons in elder times called Bucken." As early as the times of Edward the Confessor, more than eight hundred years ago, the woods of Burnham in that county afforded pannage for six hundred hogs. Pannage was the old legal term for the right to the food afforded to swine by the mast of the Beech and Oak. I believe that the still-celebrated Burnham Beeches, a few of which are portraited in the annexed illustration, were then in existence. There is a tradition that they were pollarded in the time of Canute, eight and a half centuries since. The Beech has a peculiar mode of revivification. Its trunk may be hollow—the wood entirely decayed—but one branch remaining vigorous thrusts down to the earth, along one side within the hollow, a slender stem, which roots and becomes another trunk.

The poet Gray observed that "There is a character about the Burnham Beeches distinct from all others. They are not lofty, for they appear to have been headed-down at some time or other, but they are of enormous size, and the pruning of the heads seems to have thrown a superfluous amount of vigour into the trunks. Nowhere else do the trunks of Beeches, as a rule, burst into such strange forms, or so wreath their old fantastic roots on high. Every second Beech trunk here is a study for a painter." They are still all that Gray described nearly a century and a half ago.

I consider the Beech one of the most beautiful of our forest trees; and although the most fault-finding of critics, Gilpin, is adverse, I will quote his admissions in support of my estimate: "Its trunks are often highly picturesque. It is studded with bold knobs and projections, and has sometimes a sort of irregular fluting about it, which is very characteristic. It has another peculiarity also, which is sometimes pleasing, that of

Fig. 54.—Burnham beeches.

a number of stems arising from the root. The bark, too, wears often a pleasant hue. It is naturally of a dingy olive; but it is always overspread in patches with a variety of Mosses and Lichens, which are commonly of a lighter tint in the upper parts and of a deep velvet green towards the roots. Its smoothness also contrasts agreeably with these rougher appendages. No bark tempts the lover so much to make it the depository of his mistress's name. It conveys a happy emblem—

'—— crescent illæ; crescetis amores.'
(As they increase; the loves increase.)

"Virgil was right in choosing the Beech for its shade. No tree forms so complete a roof. If you wish either for shade or shelter you will find it best

'—— patulæ sub tegmine Fagi.'
(Under the cover of a spreading Beech.)

"Sometimes we see in Beeches of happy composition the foliage falling in large flakes or layers, between which the shadows have a forcible effect when the tree is strongly illumined.

"Contrary to the general nature of trees, the Beech is most pleasing in its juvenile state, as it has not yet acquired that heaviness which is its most faulty distinction. A light, airy, young Beech, with its spiry branches hanging, as I have just described them, in easy forms, is often beautiful. I have seen also the forest Beech in a dry hungry soil preserve the lightness of youth in the maturity of age."

The surface of the soil beneath that shade is bare. The Lesser Periwinkle (Vinca minor), and a few Orchidaceous plants, such as Gymnadenia bifolia, sometimes live in the shadow, and the Morel and Truffle are fostered by it.

The Beech is one of the most useful of trees. In Switzerland mattresses are stuffed with its leaves. Its nuts yield an oil useful either as olive or lamp oil; and the cake which remains after the expression is a good food for fowls and pigs. The wooden shoes, *sabots*, worn by the French peasants are made of the wood; it is excellent for fuel, and vinegar (pyroligneous acid) is distilled from it. Turners form of it trenchers, bowls, and other utensils. Joiners and cabinet-makers employ it for furniture. If kept constantly under water it is as durable there as the wood of the Elm. The exterior rings of the wood are used for forming band-boxes. The millwright uses it for the cogs of wheels, and the wheelwright for spokes. In the coal mines it is used under the name of "Newcastle railing." Like the wood of the Lime it is used for piano sounding-boards. Tool-makers employ it for handles, and cask staves for dry goods are made of it.—G.

Arbor Day in Nebraska.—The project of tree-planting in Nebraska, and the idea of devoting one day in the year exclusively, known as Arbor Day, for the entire population to indulge in planting, originated with J. Sterling Morton of Nebraska city. The first Arbor Day was held in the spring of 1871, when 2,000,000 trees were planted. In 1872 and 1873 Arbor Day was not celebrated, but it was recommended to the farmers to choose for themselves a day in April, and set it apart for tree-planting. This year, however, the State Board of Agriculture has determined to go back to the original plan. It has been resolved that Arbor Day shall be the second Wednesday in April, and the State Legislature is to be asked to make the day a legal holiday. Each owner of land is

recommended to plant at least one tree, and the State Board will award a premium to the person who plants the largest number. It is now the custom of the Board to give a premium to the landowner who has planted the most trees on any given day in April, and at a recent meeting of the Board the prize was awarded to a farmer who set out 27,800 trees on the 28th of April, 1873.—(*American Horticultural Journal.*)

PRIMULA CORTUSOIDES AMŒNA.

Notices of this very beautiful Primrose have from time to time been made in this Journal. Its great beauty and easy culture ought to make its presence welcome in every greenhouse, where it cannot fail to be appreciated. The much-vaunted Primula japonica is not to be compared to it in beauty, though it, too, is a fine Primrose; and although both come to us from Japan, I have no hesitation in claiming for P. amœna priority and extended culture.

I have no experience of it planted outdoors, though the Messrs. Veitch who introduced it state it to be perfectly hardy. As a pot plant it is quite charming for the greenhouse, and is admirable for window culture, it blooms so freely and requires little care or attention.

In an ordinary greenhouse—one having a temperature of 40° to 45° at night, and 45° to 50° by day from fire heat—it commences to grow in February or early in March, and is in flower at the close of that month or in April. It continues a considerable time in flower, the colour a rich rosy purple. In a cold pit or frame it flowers later; but it is as a greenhouse plant that I wish to note it.

Being herbaceous, or losing its leaves some time after flowering, it ought up to that time to be kept watered, so that the leaves do not flag, and when they begin to turn yellow water should be withheld, removing the leaves as they decay. It is the best of slight shade, as all the Primulas are. I place the pots amongst those of Heaths and other hardwooded plants, whose heads afford the Primula plants an agreeable shade. The pots remain in such a position from the decay of the foliage without water, or only a little occasionally to keep the soil with a certain amount of moisture in it, though to all appearance dry.

When they begin to grow (as they will however dry the soil), at their proper season the plants are potted, turning them out of the pots, and removing any soil not occupied by roots. The smallest size of pot used is 4-inch, and the largest 6-inch. The former size will suit plants of one, two, or three crowns, which are produced at the end of short creeping stems just below the surface, lower than which they should never be potted. Keep the crowns as much in the centre of the pots as practicable. In the smaller size of pot I put one large or two and three smaller crowns; and these are a very useful size of pot and plant for working-in between larger-sized pots and plants, and for margins of stages, &c. The larger size of pots takes the plants entire which were grown in 4-inch pots the year previously, and these give plants with a profusion of bloom as large as I care to have them. They of course may be shifted annually into pots 2 inches larger in diameter, and in a few years magnificent clumps will result, luxuriating all the better for the increased depth of soil. When potting from the 6-inch pots I divide the plants into as many divisions as the plants have crowns at greater distance than 2 inches apart.

The pots are well drained, with a little of the rough of the compost placed over the drainage. The compost used is three parts turfy loam, one part leaf soil, and a half part sandy peat with a half part of silver sand, well mixed. I pot moderately firm. Water is given in proportion to the growth, always keeping moist after growth commences, and liberally when in flower. If at a distance from the glass the foliage and flower stems are liable to be drawn, but on the front shelf of a greenhouse they are all that could be wished.

There are now three varieties besides the one named—viz., alba, in habit and style of flowering the same as the original, only the flowers are white and rather more drooping; grandiflora, which has much larger flowers than amœna, concave or cup-shaped, slightly drooping, the exterior of the flower deep rose, inside white, forming a very pleasing contrast; and lilacina, which is similar to the type in habit, the ground colour of the flowers is greyish white, beautifully marked and streaked with lilac.

I have tried to cross the beautiful amœna with the Abyssinian Primrose (P. verticillata) with a view to scent, but failed; but the Japanese Primrose does not resist the pollen of that variety, and I am in hope of obtaining a break, and securing perfume for both amœna and japonica.—G. Abbey.

NOTES AND GLEANINGS.

A Fruit Show on the same extensive scale as before is to be held again at Edinburgh on the 15th and 16th of September next. The premier prize of £10 for Grapes is for eight varieties, one bunch of each. There is a second class, for which those who show in the first class shall not enter. In the collections of fruits the number of dishes is reduced to sixteen, and the collection of sixteen to twelve. There are several presentation prizes offered: Messrs. Sutton & Sons of Reading offer three prizes of five, three, and two guineas for four varieties of Melons and the same of Cucumbers; Messrs. Boyd, the horticultural builders, Paisley, offer a silver cup for stand of six varieties of Grapes; Mr. Munro of London, three prizes of three, two, and one guinea for the best brace of his new Cucumber Duke of Edinburgh.

—— We record, as most worthy of imitation, that on the evening of the 2nd inst. G. S. Boulger, Esq., gave the first of a series of Educational Lectures on Window-gardening in St. James's School-room, Norland Square, on behalf of the Notting Hill Flower Show Society. Mr. Boulger entitled his lecture "Window-gardening and Floral Culture," and gave a practical exposition of the domestic arrangement of plants adapted to the capacity of the non-botanical, of whom, as may be imagined, the Society consists.

—— The Commission for the regulating of National and International Horticultural Exhibitions in the Palace of Industry at Amsterdam has resolved, in conjunction with the horticultural establishments and similar societies and associations in Holland, to hold in 1876 in Amsterdam an International Horticultural Exhibition and Congress on an extensive scale in the Palace of Industry.

—— A correspondent writing from Chicago informs us that on February 8th the thermometer was 6° below zero, and had during the winter been as low as 29° below zero. Nurserymen have suffered severely, some losing all their plants. Let us hope by this contrast we may not speak too hardly of the severe English winter from which we are just emerging.

NOTES ON VILLA AND SUBURBAN GARDENING.

Propagating Bedding Plants.—Having last week made some remarks on the raising of seedlings, I this week take up the kindred subject of raising plants from cuttings. This mode of propagation ought now to be in full activity, and where good stocky plants of young and free growth are in request for the flower garden means should be provided to give them every encouragement to that end.

It is much more satisfactory to put out a well-grown plant which will under ordinary circumstances give a good effect at once than to plant one that has been badly grown, and perhaps in a starved condition, and which requires considerable time to recover itself. I advocate spring propagation as much as possible, ensuring as it does plants with good health and vigour to withstand successfully the ordeal of a summer's sun alternately with the smoky atmosphere so prevalent in and around large towns.

I do not advocate the growing-on of autumn-struck stock plants for summer bedding of such things as Verbenas, Petunias, and several other softwooded plants (the Geranium class excepted), which have been for months cramped thickly into pots till their roots are matted together, and the wood has become hard and the plants altogether out of character. Rather would I advise that all such things be placed where a young growth can be made from which to raise the stock of plants, throwing the others away when that is done; and it is surprising how soon a stock of plants can be raised from such growth if proper attention be devoted to them.

The conditions are very simple—viz., a moderate heat with a close atmosphere, not too dry nor too damp, but such as would be secured by placing a handlight or two on the bed, in the vinery, or even in the greenhouse or heated frame or pit. This done, the mode of putting in the cuttings may be as follows:—

Prepare pots of a moderate size, say 48's or large 60's. They must be clean inside and out. Fill up one-third with a suitable drainage, coarse at the bottom and fine on the top, consisting first of broken pots and then small pieces of charcoal; cover this with a very thin layer of moss, or in the absence of this some fibry turf, to prevent the fine soil from running down among the drainage. Next prepare the soil, which ought to be fairly dry so as not to bind when handled; it may consist of loam one-half, the remainder leaf soil well rotted, and good

sand. All this should be sifted fine and thoroughly well mixed together with the hand. Each pot should now be filled up to within half an inch of the rim, pressing the soil moderately firm; upon this add a layer of good silver sand. After preparing as many pots as are likely to be required for the first batch of cuttings take them into the house and water the whole with a fine-rosed watering pot, so that the soil may be moderately soaked without washing the sand off the surface.

In putting in the cuttings, which may be about an inch apart, it is a fact worthy of observation and practice that each cutting should be thrust into the sand without previously making a hole for it. This ensures the base of the cutting being placed firmly in the soil, but in order to do this easily and without injury to the cutting every pot must be again watered just as it is going to be used, which renders the sand soft, and consequently the cutting is easily thrust down into it. After the pot is filled with cuttings it must once more receive a gentle watering sufficient to float the sand, which when the water drains out settles closely round every cutting, fixing it firm.

The after-treatment of these cuttings must not be forgotten, for wherever they are placed they should have the lights taken off once a-day, generally in the morning, and allow them to dry themselves. This should be done regularly, because it is a preventive against damping-off, which so frequently occurs among such tender things as these. During the time they are rooting they will grow considerably, but after that has taken place the tops should be pinched-off, which will make another cutting, and so the stock may be quickly increased. The rooted cuttings thus treated will soon break into growth at each joint, when no delay should take place in having them potted-off.

I may here remark that the preparation of the cutting is very simple. There is no need for it to be cut to a joint, provided it is thrust into the soil up to the first pair of leaves, when it will soon throw out roots. Almost every kind of softwooded plant may be propagated in the above way, and it enables so many more cuttings to be taken from a plant, and a stock is thus raised more expeditiously.

The growth must be young and healthy, otherwise the system will not be so successful. Hard wood seldom roots freely, let it be propagated which way it may, neither is it so likely to make a good plant at any time as a cutting from crisp young growth. —Thomas Record.

DOINGS OF THE LAST AND PRESENT WEEKS.

KITCHEN GARDEN.

March is proverbial for its changes. It came in boisterous enough this year, with frost every night for the first week. On the first day of the second week it was very mild, the wind blowing gently from the south, and for two days more we had western breezes. The wind then suddenly changed to the cold quarter, and the night temperature, which had risen to 48° and 49°, as quickly fell to 26°; yet the winds have been drying in their nature, and gave us an opportunity to fork over the surface of the ground wherever it had been lying as it was dug or trenched in the autumn. Ran the hoe through autumn-planted Cabbages. The ground had become hard and required to be broken up to some depth, and for this purpose a swan-necked draw-hoe is much better than the Dutch tool. We have tried different sorts of Cabbages for this crop, and find the Dwarf Early York to be the best. Enfield Market will give the largest produce from a given space, but they are coarse-looking. Even the farmers who grow for market plant large breadths of Early York.

Some Cauliflower plants in boxes will be planted out as soon as the weather is favourable. The ground has been turned over and is now quite dry on the surface, and will be in good condition for the crop. Pricked out Onions from the rows where they had been sown thickly in autumn. The plants are put out in rows about 9 inches apart and from 4 to 6 inches between the plants. Autumn-sown Onions are seldom attacked by the maggot, and this system should be adopted in gardens where the maggot is troublesome.

Sowed Brussels Sprouts on a piece of poor soil: this is one of the most valuable of our winter vegetables, but the plants often club with us when sown late, and early-sown plants are more free from the maggot. Forked over the ground lightly between rows of Peas in preference to hoeing. Planted out Lettuce. A little seed of Hicks' Hardy White Cos had been mixed with the autumn-sown Onion seed, and some of the plants had been put out in the autumn. This year those planted last season are a comparative failure, while the plants that were not moved are in good condition. Sowed Celery in a warm border out of doors. The soil was wet and unsuitable, but by placing some fine dry loam on the surface an excellent seed bed was obtained. Sowed more Radish seed also in a sheltered place; the first sowing in the ground vineries has been thinned out. Any glass protection that can be placed over early vegetable seeds at this season is of great advantage to the crop.

Planted out some Seakale plants on rich and well-worked ground. The old plants that have been forced may be used for this in addition to the seedling plants of last year, which were too small for potting-up for forcing. Coal ashes placed over the crowns is of some advantage to the plants. About the end of this month or early in April is a good time to sow the seeds of Seakale.

FRUIT AND FORCING HOUSES.

Pineries.—But little can be added to the remarks in the number for March 4th. Plants that have ripe fruit or fruit that is nearly ripe ought to be taken out of the house where the temperature is 70° at night with a moist atmosphere, as in such a place the fruit soon shows symptoms of decay. The most convenient way is to cut the fruit, and remove it to a dry room where the temperature does not vary much in the twenty-four hours. If the fruit is not quite ripe, and is also sound when it is cut, it will keep for a month after being cut from the plant. Those plants that are furnished with suckers ought to remain in heat until the suckers are large enough for planting out; they grow more quickly on the parent plant than they do if they are removed and potted in a small state.

Those who grow only a very limited number of plants will find it a good plan to plant the suckers just when they can be obtained; and when the plants have well filled the pots with roots, though they must not become pot-bound, let them be potted into the fruiting pots at once. We used to pot the plants into 9-inch pots first, and then into the fruiting pots, thus making two shifts; after trying both ways it has been found that the greatest advantages are in favour of the one-shift system. We have some autumn and winter-struck plants of Smooth-leaved Cayenne and Charlotte Rothschild that will be potted as soon as possible. The compost which has been described in previous numbers is mixed up and placed in the house for a day or two to become warmed before using it.

Dwarf Kidney Beans.—A succession of these can be kept up by sowing a box thickly with them, and potting them off when the seed leaves are fully developed. We have found them bear most abundantly and continue the longest in bearing when four or five plants are put into 7-inch pots. They are kept free from insect pests by daily syringing, and the minimum temperature is not less than 60°. It is marvellous the quantity of pods that can be gathered from two or three dozen pots of the little Newington Wonder if none of the pods are allowed to become too old. The soil should be four parts good turfy loam and one part rotted manure.

Strawberries.—The whole of the pots of Black Prince have been removed from the forcing houses, to be succeeded by Keens' Seedling. Some of the most extensive growers have told us that their plants have not thrown-up so freely as usual. Probably this was more owing to the unfavourable weather at the time than to the fact that the crowns were not thoroughly matured last autumn. We had an abundant crop of Black Prince, though the fruit was not so large as usual. Keens' Seedling is now in flower, and the abundance of well-developed blossoms seems to ensure a good set. Alternate waterings with weak liquid manure are very beneficial to the plants as soon as the first young leaves are formed.

MUSHROOM HOUSE.

The details of work in this department are so much alike from week to week that frequent remarks are only a repetition. The spent manure from the beds is very useful for mulching newly-planted trees, Roses, shrubs, &c., or it may be laid-up in a heap, when it will be equally valuable for mulching all growing crops during the summer months. None of the beds need be empty at this time, but as soon as any of them are quite exhausted fresh beds should be made up. Our own experience has been in favour of mixing a portion of cow manure and a little fibry loam with the horse droppings. Splendid large fleshy Mushrooms have been produced by mixing horse droppings, cow manure, and loam in equal proportions.

The most important matter in making-up Mushroom beds is the state of the material at the time. This must be thrown-up in a heap sufficiently long to allow of the rank steam being thrown off. If it is too wet it must be spread out on the floor of an airy shed for a few days until the superfluous moisture escapes. If the bed heats violently after being made up, this will show that the material has not been well prepared.

The quality of the spawn should not be doubtful, and expense should not be spared to obtain the best in the market. The bricks should be broken-up into pieces about the size of a pigeon's egg, and the bed may be spawned when the temperature has fallen to 80°. The surface of the bed should be pressed down firmly, and when in the course of a week after spawning the dressing of loam is put over the bed, this must also be beaten down firmly with the back of a spade.

PLANT STOVE.

The sun has now begun to act very powerfully upon the glass, and it has been necessary to put up the shading, not as a fixture, but to roll up in dull weather, and to be used only in hot days. A little sunshine in such cold weather as we are enjoying at present will do good instead of harm. Again, some plants require all the sunshine they can get; but as it is necessary to

grow them on the same stage with others that would be injured by it, a compromise must be made.

Plants of Ixoras that were in flower at midwinter, after being cut-back a few weeks ago, are now starting freely; they must be exposed to the light and freely syringed. Stephanotis, Allamandas, and other climbers are now making free growth, and require tying-in to the trellis. Those in pots intended for specimens should not be tied-in closely; the young growths should be tied-out until the flowers are nearly opened, when they should be regularly arranged on the trellis intended for them.

Dendrobiums that flower in the spring and summer months, such as D. Bensoniæ, D. densiflorum, D. Farmeri, D. Dalhousiauum, D. McCarthiæ, and many others, are now throwing out their flower trusses after being kept dry at the roots all the winter. They now require to be well soaked with water at the roots, but not overhead. The water should be warmed by standing in pots close to the hot-water pipes for a few hours. Some of them are very liable to be attacked by red spider, and the young growths are sometimes totally ruined before it is noticed. D. Devonianum is generally attacked first. In the case of this species the best treatment is to syringe the plant every day, or, if this is not convenient, the leaves must be washed with a sponge and soapy water on the first appearance of the spider.

Oncidiums, such as O. ampliatum, O. phymatochilum, &c., that throw-up the flower stems shortly after the pseudo-bulbs are formed, must be watched, as slugs, should any be in the house, have a particular fancy for the young flower spikes as they rise from the base of the bulbs. In the house devoted to cool Orchids it is more necessary to shade from sunshine than it is in the more tropical department. About 45° at night is the temperature maintained at present. The flowers of Odontoglossum crispum had become infested with green fly, and as fumigating is very dangerous they are swept off with a small camel-hair brush. The flowers are also very easily damaged by spotting, but this may be avoided by judicious airing and an atmosphere not saturated with moisture, but only of moderate humidity.—J. Douglas.

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Glasgow.—March 24th, June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.

Jersey.—May 5th, Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

Bath.—May 12th, September 1st and 2nd. Mr. B. Pearson, 13, Milsom Street, Sec.

Coventry.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.

Durham and Northumberland.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.

Leeds.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.

Fareham.—June 23rd. Mr. H Smith Sec.

Exeter (Rose Show).—June 25th. Mr. J. N. Gray, Queen Street Chambers, Hon. Sec.

Wisbeach.—June 30th. Mr. C. Parker, Hon. Sec.

Wimbledon.—July 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Sunnyside, Wimbledon, Hon. Sec.

Brecon.—July 22nd. Mr. W. J. Roberts, Sec.

Cleckheaton.—July 24th. Mr. S. H. Williamson, Hon. Sec.

Southampton.—July 31st and August 2nd. Mr. C. S. Fuidge, 32, York Street, Lower Avenue, Sec.

TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—*Farmers' Year-Book and Graziers' Manual.*

Ewing & Co., Norwich.—*List of New Roses.*

Downie, & Laird, 17, South Frederick Street, Edinburgh.—*Descriptive List of Garden, Flower, and Agricultural Seeds.*

William Montgomery, 19, Gordon Street, Edinburgh.—*List of Garden Seeds and Bedding Plants.*

TO CORRESPONDENTS.

Advice (*Crito*).—We are much obliged by your suggestions, though we cannot adopt them. We long since concluded that a brother editor was right when he wrote, "Editing a paper is like carrying an umbrella on a windy day. Everybody thinks he could manage it better than the one who has hold of the handle."

Bookseller's Error (*Inquirer*).—You should have returned the book at once and refused to pay for it. Even now, if you have not cut the leaves, and as you told the bookseller of the mistake, if you return the book we think he could not make you pay for it. Think whether it is worth the trouble and annoyance. You have a good book.

Lists of New Plants (*J. F., Haddington*).—There is a list down to 1855 in the second supplement to Loudon's "Encyclopædia of Plants." A list of all new plants of the previous year is published by us annually in Hogg's "Gardeners' Year Book."

Various (*Marley*).—We cannot tell who would purchase the New Zealand Ferns. Write to some of the florists who specially advertise Ferns in our columns. Melon seeds forty years old have been known to germinate, and gardeners think the plants are not so liable to be over-vigorous if the seeds are two or three years old. The seeds of a Composite plant which you enclose may germinate; you can easily try them.

Mildew on Plants (*H. A. P.*).—Dust them and the Vines also with flowers of sulphur; it will kill the fungi and prevent the spores spreading the infection.

Mulch over Rose Roots (*A. D. U.*).—Remove the undecayed straw, fork-in the remainder shallowly, and mulch again in the spring.

Hollyhock Seedlings Diseased (*R. L.*).—It is the "Hollyhock disease." No remedy is known. Cut them down immediately, and sprinkle flowers of sulphur thickly over the stumps and surface of the soil. The experiment is worth trying, as the leaves are only slightly affected. Chloride of lime would kill the plants.

Hollyhock Leaves Diseased (*J. L.*).—They are attacked by the parasitic fungus Puccinia malvacearum; a drawing and description are in our No. 687. No remedy is known, and the best course is to cut down and burn every plant affected, for the spores of the fungus will spread the infection.

Ferns (*A Lover of Ferns*).—In our volumes xxii. to xxvi., both inclusive, are a series of papers on them. If you need a book on the subject you will find full information on the species and culture in our "Fern Manual."

Arum (*J. Wicketts*).—What you call "the White Arum" we suppose is the Richardia æthiopica. One flower being within another is an uncommon sport which most flowers produce occasionally. Your Richardia will not do so again next year.

Humea elegans (*Amateur*).—The proper time to sow the seed is the first week of May in a gentle hotbed. Pot the plants off singly when large enough to handle, and grow them on in a cold frame during the summer. In the autumn remove them to the greenhouse, assigning them a light and airy position.

Deutzia gracilis Unhealthy (*W. S. B.*).—It is likely from the description you give that the plant has received some injury at the neck or collar just above or at its junction with the soil, which has caused the decay of the bark, and prevented sap being transmitted to the shoots and leaves. It will not, we think, recover, but we should keep rather dry, as heavy waterings will only hasten the decay. It may, however, be only the result of a chill, and in that case it will be enfeebled, but will recover.

Celeriac Culture (*Winton*).—Sow the seed in a seed pan early in April, and place in a house with gentle heat, and when up remove to a cold frame and harden off, prick out when the rough leaves are an inch high in good rich soil in an open yet warm situation, and shade from bright sun. Keep the plants well watered, and when large enough plant out in well-manured trenches, putting in the plants in double rows 9 inches apart, and water thoroughly. It does not require to be earthed-up like Celery, but should have a little earth to protect the Turnip-like root from frost. It is useful for soups, and is by some considered a nice addition to salads. In severe weather it should be protected from frost by a covering of litter. The best stewing Celeries are the reds, and good alike for any purpose is Leicester Red.

Destroying Daisies (*J. P.*).—Salt will not destroy Daisies, at least not unless it be applied in such quantity as would also destroy the grass. You may, however, apply this month a dressing of salt at the rate of 20 bushels per acre, which is a preventive of slugs and worms. It will encourage the growth of the grass and kill the moss. The sand will be of no use, but a dressing of short manure or rich compost—if the latter adding to it one-sixth lime—would be highly beneficial. After clearing off the rough particles sow with Grass seeds, not omitting Clovers—Trifolium repens 8 lbs., Trifolium minus 2 lbs. if the land be strong loam, and if light reverse the quantities of the Clovers named. Roll well after sowing. These, however, will not banish the Daisies. The best remedy is to grub-up the roots, employing boys or women, who with knives will grub up a great many in a day; this persisted in is the most certain means of eradicating these pretty weeds.

Gardenia Treatment (*A. D.*).—The plants ought now to have brisk moist heat to start them into bloom and growth, and are the better of bottom heat. They should be moderately watered at first, but kept moist, increasing the supply as the buds swell. When the plants have done blooming cut-in any straggling growths if it be required, and sprinkle with water overhead, repotting if necessary, and by a moist and brisk heat encourage growth. When that is complete gradually withdraw from the bottom heat, keep drier and cooler, and in autumn and winter give water only to keep the leaves fresh. If the plants are sickly from a sodden sour soil repot at once, providing good drainage, plunge in bottom heat, and water carefully until the roots are working freely in the fresh soil, then water more copiously.

Plants for the Back Wall of Vineries (*Mr. John Kelly*).—Camellias, also Orange, with its allies the Citrus family, are good. Both may be planted 12 feet apart, but it will be a number of years before they meet unless you can put out large plants. Lucelia gratissima is also a fine plant for a wall, and one of the best flowers for cutting in autumn and early winter. If the plants are small they ought to be planted at half the distance apart.

Vines Bleeding (*Idem*).—Dry the cuts with a hot iron, and at once dress with Thomson's styptic or the patent knotting used by painters. The temperature you name will not stop the bleeding now it has begun.

Lily of Valley (*Idem*).—Flowers without leaves is the result of being brought on too quickly by high temperature and the plants not being sufficiently near the glass. They are, however, subject to this when forced early, and more so this year than usual, probably by the drought of last year ripening the crowns more thoroughly and developing the flower buds to a higher degree than when the season is more moist. Mr. Bull of King's Road, Chelsea, as well as Mr. Linden, deals in economic plants.

Potato for Main Crop (*Portcullis*). — For your purpose we advise Walker's Regent. You will require about three bushels. It is a heavy cropper, a capital keeper, and of excellent quality. It will not, however, be in use until September; you will therefore require a few earlies and second early, about half a bushel of each. The early may be Myatt's Prolific, the second early Lapstone. The early may be in rows 2 feet apart, and 1 foot asunder in the rows; the second early 2 feet 3 inches, and 15 inches; and the main crop 2 feet 6 inches, and 18 inches in the rows. The seed would be most economically purchased of some neighbouring grower.

Sweet Williams (*Idem*).—It is a good time to plant nice plants with good balls for this year's flowering, but seed sown now would not flower this year. The first week in April is a proper time to sow Sweet Peas and Mignonette.

Thorn and Privet Hedge (*J. R. W.*).—The Privet would overgrow the Thorns or quicks, and it would not as a fence against cattle be so good as a quickset hedge only, though from its evergreen character is preferable as a shelter for gardens. To give a semi-evergreen character to the hedge you

may plant a common Holly along with the Thorns one in every yard, it being much better as a fence plant than Privet, which is too weak for resisting cattle; but nothing can be better than a good quickset hedge.

ALLAMANDA SCHOTTI (*Amateur*).—The treatment to which the plants have been subjected is proper, providing they have not been kept so dry in winter as to cause the wood to shrivel. If the wood be plump and sound you may safely purchase the plants.

ECONOMISING OLD LIGHTS (*Amateur Vinedresser*).—Cool vineries ought to have a south aspect; an east one would not, we fear, receive the requisite solar heat nor retain it so as to ensure the ripening of the fruit. It would answer better as an orchard house than as a house for Vines. The lean-to would be the best form of house. We should plant the Vines in front, and run up each Vine with four rods at about 3 feet distance apart. Chasselas Vibert (white), Esperione (black), and Cambridge Botanic Garden (black) are the most likely kinds to succeed in such a house. We do not, however, advise them, but instead we should form of the lights an orchard house, having the lights fixed perpendicularly at 7 feet distance from the wall, having about 18 inches of boarding at bottom, one half of it to open for ventilation, and an entirely new roof. By having this fixed beneath the coping of the wall you will have about 2 feet 6 inches of fall in the 7 feet of width. A row of bushes and pyramids in front and the walk at back will leave the wall available for fruit trees, and suitable for Peach, Nectarine, or Apricot. The front will be admirably suited for Plums, Cherries, and Pears.

FOREMAN'S QUERIES (*S. H. G.*).—You cannot do better than write to the gardener. You are certain to receive a courteous reply, and the information will be authentic.

NAMES OF PLANTS (*J. W.*).—1, Woodwardia radicans; 2, Aspidium angulare; 3, A. coriaceum (capense, *Willd.*). (*Dollond*).—Pomaderris elliptica. (*Wm. Hodgson*).—Specimens insufficient. (*J. F., Teddington*).—1, Nothochlæna sulphurea; 2, Pteris longifolia; 3, Adiantum hispidulum; 6, A. formosum; 4, Pellæa hastata; 5, Asplenium viviparum. (*Juvenile*).—1, Adiantum hispidulum; 2, Asplenium fontanum; 3, Aspidium lobatum.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE EXHIBITION DORKING.—No. 11.

BY T. C. BURNELL.

THE DARK DORKING HEN should be similar in shape to the cock, with a square, broad, and lengthy body set on short legs. The comb, if single, should be large and falling to one side, a small upright comb being a great eyesore. By some it was thought impossible to breed cocks with upright combs from hens whose combs fell over, but this fallacy was contradicted by Mr. Hewitt in the *Journal of Horticulture* for June, 1867, and I copy his notes, which will be interesting and instructive to many. Mr. Hewitt says:—"In giving my opinion as to the formation of the comb of a Grey Dorking hen, I quite agree that the comb should be of moderate size, well serrated, and hanging over the face on one side. The theory propounded of breeding from what is commonly known as a 'prick-combed' Grey Dorking hen has been again and again attempted, but I never yet knew a single individual who persisted in the experiment a second year, for disappointment was the invariable issue, and the chickens thus produced proved utterly useless for exhibition. Anyone purposing to breed Dorkings I would strongly advise to mate together a cock having a perfectly upright comb with hens whose combs fold and then turn over the face, it matters not on which side. He will then find, if well-bred stock birds, that all his chickens will have combs exactly of the same formation as the parent birds. In Spanish fowls the same rule again holds good. It is only great age or want of health and condition that will cause the combs of either Spanish or Dorking cocks to fall over if they are truly-bred birds. In the latter case it very frequently happens that restored constitution causes the comb to become again as exact and firmly fixed as ever. The different formation of the comb is in the breeds referred to simply characteristic of sex, as in the mane of a lion or the antlers of a buck."

As regards the colour of a Dark Dorking hen a good deal of latitude is allowed, provided the general appearance of the bird is of a rich dark colour. Whatever a few may say to the contrary, it is impossible to ignore the fact that the old Brown and Light Grey birds do not now meet with favour either from judges or exhibitors, partly owing to the fact that the Dark hens handle the best from being more tightly feathered, and partly because they present a more attractive appearance to the eye. My taste inclines in the hen to a jet-black neck hackle and tail, the back and wings being of a dark grey colour, and each feather spangled at the ends with a darker marking, the shaft of each feather being distinctly white.

This latter feature is invariably found in all good Dorking hens, and adds very much to the general appearance by contrasting with the dark feathers. With a black hackle I like to see a salmon-coloured breast, but the hackle is often striped with white, and the breast colour may be of any tinge from light salmon to dark chocolate, as long as it does not present a washed-out appearance.

Colour is far more difficult to obtain than size. The latter may be obtained by good and judicious feeding and breeding from large-sized birds not too nearly related; but nothing will bring colour unless it is in the strain. Beginners are apt to think that all they have to do is to buy a couple of good hens and a highly-commended cockerel at a large show, and to breed from them, but this will nine times out of ten end in failure unless the cock comes from a good strain; as, no matter how dark and good the hens are, if the cock be not also bred from dark-coloured birds it is impossible to say what the chickens will turn out. Before buying a cockerel to breed from I like to see what the stock hens of the yard are like. It is very bad policy to take the show birds as a sample, as these have very likely been bred by someone else. Though the darker-coloured cocks as a rule are most likely to breed dark chickens, this is by no means a certainty, and we shall never know what our chickens are to be like unless we know for certain that the cock comes of a good strain.

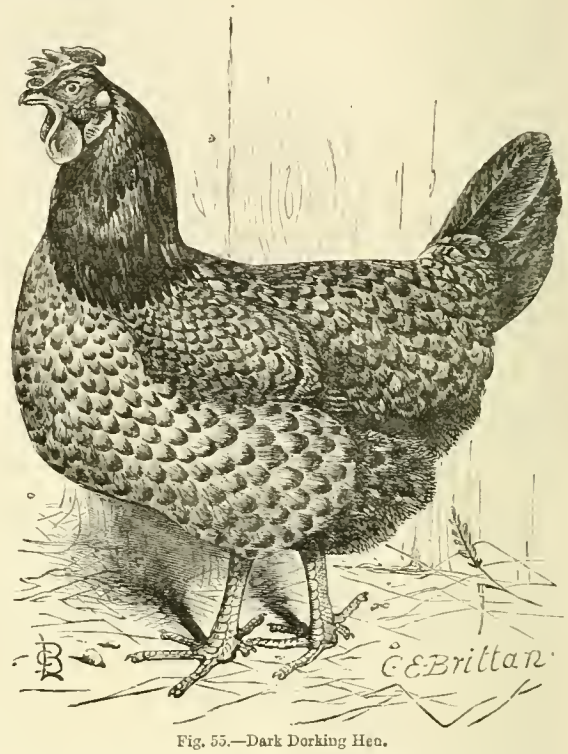

Fig. 55.—Dark Dorking Hen.

The principal defects to avoid in a Dark Dorking hen, in addition to what I have alluded to when speaking of the cock, are upright comb and "sooty" feet, the latter being much commoner in the hens than in the cocks, as also are white earlobes. A red or rusty colour on the wings is also to be avoided.

Dorking eggs are white and unusually large. The chickens when hatched are very pretty, and should be uniform in appearance, with a broad dark band down the centre of the back, and with two narrow white stripes on each side of it. As a rule the little chickens with the broad band of colour down the back of a sound dark tinge are more likely to make dark chickens; and even from the very best birds it will be futile to expect more than two or three in a brood to reach the required standard of shape, size, comb, colour, and feet, while not one bird in a thousand is perfect in every respect.

The best of rearing a number of Dorking chickens is, that the "wasters"—birds which can never pass muster—are at the very best for the table when at about ten weeks old, and should then weigh from 2½ to 3 lbs. each. I constantly weigh my chickens, and find that cockerels at two months old should weigh from 2¼ to 2½ lbs. if they are ever to be the heroes of a show pen. At four and a half months old 7 lbs. is a fair weight, and at six months many weigh 9 lbs., and some 10 lbs. Old cocks will weigh from 9½ to 14 lbs., and hens from 8 lbs. to 11 lbs. I of course allude to show specimens; but a cock weighing 10 lbs., if dark and perfect, is likely to win many prizes, as is a hen of 8½ lbs. These weights are mentioned only for the sake of comparison, and birds may generally be made 2 or 3 lbs. heavier by fattening; but this would be worse than useless, as birds now are never weighed, and it is frame and bone which carry the day.

It is impossible to give a standard of points of any real use, as judges will always differ as to the amount to be allowed for condition, nor will they agree as to the relative value of shape, size, and colour; but the following scale gives my own idea on the subject. Allowing one hundred marks for a bird perfect in

size and every fancy point, I would deduct the following marks for the following defects :—

Want of shape	from	5	to 25	points
Want of size	,,	5	25	,,
Bad colour	,,	5	15	,,
Badly-formed feet and toes	,,	2	15	,,
Defective comb in hen	,,	1	5	,,
Defective comb in cock	,,	2	10	,,
Sooty feet	,,	2	15	,,
Slight bumble foot	,,	10	20	,,
Spur outside (cock)	,,	15	20	,,
Absence of white shaft from the hen's feathers	,,	5	10	,,
Want of condition	,,	15	25	,,
White earlobe	,,	1	3	,,

All deformities, bad bumble feet, spurs right outside, and very dark feet are fatal disqualifications, and I think badly-crooked breastbones should be so too.

HOUDANS.

Like "D., *Deal*," I am exceedingly disappointed with my Houdans as regards laying, although in other respects they far exceed other breeds except the Crêve and Dorking, and they surpass them in hardiness.

Having read in your Journal of the excellent laying properties of these birds, I determined to obtain a yard of them, and procured four Houdan hens with a cock (not related) in January 1874. From these I reared twenty-nine pullets, all of which are now above ten months old; with these pullets I put six cross-bred hens in order to have in the yard exactly the same number of hens as I had last year, which consisted of thirty-five farm-yard hens.

Last year's result from thirty-five crossbred fowls during the months of January and February (nine months old) was 621 eggs. This year's ditto (ten months old) Houdans, 301 eggs. The eggs I now obtain from this yard are half of them from the crossbred hens; their eggs being easily distinguished by their brown tint.

Besides the Houdan yard I have one of Light Brahmas (nine hens and a cock), these have laid this year 307 eggs. I have another yard of Black Red Game, twenty-three pullets which have laid since Christmas 421 eggs; also I have three Black Hamburgh pullets, which have laid this year 103 eggs.—J. Shelswell, *Banbury*.

THE ENGLISH OWL PIGEON.

I find, after reading "Wiltshire Rector's" remarks on this Pigeon, I must add something lest I be misunderstood. The Rector's analogy as to the African being to the English Owl as the Short-faced Almond is to the well-bred flying Tumbler will not, in my opinion, hold good. Flying Tumblers are fancied and bred for their performances in the air, and he who will have them nearest perfection must not be too particular about feather or appearance. Short-faces, on the other hand, though undoubtedly bred down from common Tumblers, are bred entirely for appearance and fancy points. If the Rector's analogy is good, then English Owls, like those of the present day or similar birds, are the progenitors of the fine Africans now imported. From this idea I must dissent, and rather hold with "Bubo" that the English bird has degenerated in English hands from unskilful breeding.

To the proof of my assertion I first mention the article on the Owl in the Treatise on Pigeons (1765):. "The Owl is, according to Mr. Moore, a small Pigeon very little larger than a Jacobin, which might be their size in his time; but at present they are brought to such perfection that they are hardly if anything larger than a very small Tumbler. Its beak is very short, and hooked over at the end like an Owl's, from whence it takes its name; the shorter it is the better. It has a very round button head."

If a fine African Owl and what is reckoned a fine English one (such as comes to the front at the best shows) is taken up and compared with this description written in 1765, I hold it will not apply to the English bird at all, but eminently to the African. Leaving out mere size, there is little left but the frill or purle to indicate what the English bird is. Some of the crossed dusky-coloured birds have certainly fair heads, but can a real powder-blue English Owl be produced with the formation of head and beak as described in the foregoing quotation? If it can, then I will allow it to be an Owl, although double the size of the African. At the same time it is clear that the size is a sign of coarseness, and that altogether the breed has lost that finish so well described by the writer of the Treatise (1765).

Returning to the Rector's analogy of Short-faces to African Owls. The former if very fine could not be trusted to fly, leaving out the risk of loss, because they are not able; while, on the other hand, the African bird has his wings clipped up, and is as smart on the wing as his English very distant relation, which I have proved.

When in India I had a very fine pair which I had from Mr. Jamrach, who brought them out on one of his expeditions in search of tigers. He had them from Messrs. Baily, the importers. The climate, being something like their native one, suited them so well that they bred as freely as common Pigeons, and so true to points that I was convinced the breed is a well-established one, not like the English Owls that I had beside them, and from fair-headed specimens of which the greater number came very mousey-faced.

As I said before, the English bird is worth preserving for colour's sake, in the hope that that may be engrafted on the finer bird; but he is not in my opinion worth preserving for anything else, having evidently had the bar sinister engraved on his escutcheon some time between 1765 and now; at least I judge so when I read what he was and look at what he is.—J. C. Lyell, *Monifieth, Dundee*.

CLASSES FOR THE MEALY POUTER.

The prevailing colours of semi-wild Pigeons inhabiting field dovecotes and ruined buildings in this country and the continent of Europe, also the Hindoo temples and mosques of Hindostan, are blue with black bars, and blue-chequer. Amongst all these it is no unfrequent thing to observe some mealy and red-chequered birds. These latter colours, then, seem the first variation nature makes in half-domesticated Pigeons, and next an occasional albino or pure white. It is therefore owing to the fact that they are the most natural, that Pouters of these colours have always been perhaps hardier and generally finer developed as to style and size than the artificial black, red, and yellow. I think late writers are agreed that blue and mealy do not give the breeder one tithe of the trouble as to colour that the artificial colours do.

On going back to the earlier writers, I find Moore places the black before the blue, and the yellow before either. Thirty years later the writer of the Treatise (1765) values them in the same way, and places red between black and yellow.

Circumstances may alter cases, as for instance at the present time reds of the best tint are so scarce that they are more valuable than yellows, birds of which are still to be met with of very good colour though also scarce. Yet I think we may take for granted the respective values placed on the colours by the old writers, and we shall, no doubt, find when reds of colour become more common that the difficulty of keeping to the right tints will make the colours stand—first, yellow; second, red; third, black; fourth, blue. After these the only others worth breeding for themselves are the barred colours—viz., silver, yellow mealy, and the common or red mealy. Both as regards beauty and from the fact that silver and yellow mealy are scarce and artificial colours, they would in my opinion stand far before the common or red mealy if they could be produced equal in Pouter points with it. Whether they ever will be bred so is another question. I therefore put—fifth, silver; sixth, yellow mealy; seventh, red mealy. After these there remain blue, red, and yellow chequers of various shades, sandies of the same, dun and dun chequers (colours I never saw, though I believe they have existed), Splashes all the way from those with only a grizzled tail to half-coloured or badly pied birds, and last pure whites, which should in my opinion come eighth on the list; for should any of the seven colours I have numbered be not only equal in style and size to a white, but well marked besides, it is a more valuable bird.

Here, then, is what I would consider a good schedule for a Pouter show, the sub-divisions into classes of cocks and hens, old and young birds, being made according to circumstances. First, yellow; second, red; third, black; fourth, blue; fifth, silver and mealy (yellow or red). Of course the red mealy has the best chance here, yet yellow mealies have been bred very fine; sixth, white; seventh, any other colour to include dun, sandy, chequers (blue, red, yellow, or dun), and Splashes with not more colour than a marked tail, and ticked about the head and neck.

The attempt on the part of some to wipe out and utterly ignore at shows some of the off-colours found in Pouter Pigeons will never succeed. At the same time is there not a danger of carrying the recognition of them too far? as for example at the last Kilmarnock Show, where I find the following extraordinary classification :—First, blue or black; second, red, yellow, or mealy; third, any other colour. I understand from this that reds and yellows to beat mealies must be at least as good in the first four Pouter properties. Where are such reds and yellows to be had? Without particularising birds it is well known that there have been, and perhaps yet are, mealies so fine that no black, red, or yellow could stand a chance with them. The only fair schedule where there were only three classes would be—first, yellow, red, or black; second, blue, silver, or mealies; third, any other colour. Perhaps it is the idea of some who have waded through the late Pouter controversy that those who took the part of the off-colours have plenty of them and produce many. Out of thirty birds I have only two off-colours, and no fancier I know has a greater proportion, but some have less. They are used according as they are bred. In the hands of

their owners they are of great value, while in the hands of others who did not know their breeding they might be of as great loss if wrongly matched. Success in breeding depends on the knowledge of how all one's stock is bred.

In conclusion, I do not believe that the late Pouter controversy has done anything to alter the position of off-coloured Pouters in the least. I believe those who wrote most against them know their value, and would give as much for good specimens, and perhaps more, as those who sided in their favour. Old Moore says, "The plumage of the Pouter affords a very great variety. The pieds are most universally esteemed. Under these may be ranked" (for mark, there were other colours) "the blue, black, red and yellow pied."—J. C. LYELL, *Monifieth by Dundee.*

In the pages of a contemporary I was surprised to see a letter from Mr. Wallace of Glasgow, in which he uses very tall language about a mere nothing. He says, "To Mr. Huie's assertion I give the most unqualified contradiction. Neither he nor Mr. Ure were ever members of the North British Columbarian Society." I feel it to be my duty to remind Mr. Wallace that the North British Columbarian consists of the mere remains of (with a few honorary names added) a Society of which Mr. Huie was one of the original founders, and no member did more to establish the reputation of that Society than he did, the name of which has been of late years only altered to "The North British Columbarian." I know that Mr. Huie wrote articles for three of the Glasgow daily newspapers when connected with that Society, which was the means of bringing out the public to a large extent to its exhibitions, and placing it on a footing of respectability, which Pigeon shows in Glasgow had never before enjoyed; and I do think Mr. Wallace acts a small part in making use as he does of the mere change of the name of a Society of which the mainsprings are now gone.

The editorial note following the letter in question is behind the times. It is certain that Mr. Huie and Mr. Ure advocated the Mealy Pouter and bred them to perfection many years before your contemporary was dreamt of, and for aught that I know years before its editor saw the light of day.—JAMES BRUCE, *Dunfermline.*

NORTHAMPTON SHOW OF POULTRY, &c.

WE have received another report of this Show, from which we extract the following:—

RABBITS.—The Lops in the Self-coloured class were not numerous, but good, and one pen empty. The first was a Fawn doe, very good in all properties, 21¼ inches by 4⅝ in ear. Second was a Black buck, partially moulted, small in eye, but good in all other points: ear, 21¾ inches by 4⅞. Third was a Silver Fawn buck, 21½ inches by 4¼. Lops, Broken-coloured, was a good class and the competition close. First was a Black-and-white doe, perfect in style, marking, and eye; ear, 22 inches by 4¾; rather small in size. Second, a Tortoiseshell doe, not a good colour, but right in all other respects, 22½ inches by 4¾. Third, a Black-and-white buck, a little short of marking, very grand style and carriage, good eye; 21½ inches by 4⅞. Pen 1214, very highly commended, Black-and-white, too gay in colour; 21¾ inches by 4⅞. 1208, Fawn-and-white, very highly commended; 20 inches by 4½. 1212, a good Rabbit in all respects, and would have been first, but one leg was crooked. Angoras were a very good class. Mr. Swetman's very large doe first. Second, a smaller Rabbit, but very fine in wool, and with such ears for shortness and shape as we have not seen in the show pen before, and it is quite a moot point with us as to whether this Rabbit's fine qualities should not have been placed before mere size, other points being equal. The third, from Mr. Swetman, was also large and good. Mr. Thompson's highly-commended buck also a near run. Himalayans formed a large class, but, as a whole, nothing out of the common, although there were some really good specimens, as the one shown by Mr. Mason; the second, which was small and young; and Mr. Pickworth's buck. Dutch were not good, and the first award was to a very young Rabbit grey in colour but perfectly marked if we except that the line in front did not extend through the ears; the second and third, adult, Blue, and good. Silver-Greys were *the* class of the Show—such a class, in fact, as we have never seen equalled, and every pen mentioned separately; six being selected as the recipients of the prizes, were taken out and placed in separate pens in an equal light, the remainder, as a rule, losing only in the extremities being a little too dark, the heads especially. Of the above-named six the first was one of the most equal Rabbits we have ever seen, the feet, nose, and especially the ears, being exactly like the body, and the surface silvering of the most correct shade, and neither mossed nor mealy. Second was a large Rabbit, perhaps the largest in the Show, but rather gaunt-looking, showing want of condition, and not of the same nor as correct a shade of silvering. Third a little smaller than above with grand body colour, but not as light on feet, nose, and ears as on body, but the next best in silvering. Fourth not as good in silvering, and rather darker on feet and nose; and pen 1260 close upon the last-named.

From the above remarks it will be seen that evenness and silvering take the lead over sheer size, which agrees with our opinion from long experience; colour, as in the Silver-Grey Dorking, being far ahead of size, although the latter is a very desirable property as enhancing the value of the skin.

In the Variety class Belgian Hares won the prizes, the winners being quite clear of the rest, most of the others being good in fore quarters, but only a common wild-rabbit colour on the hind quarters.

In the Selling class for any breed, Lops excepted, the first was a better Belgian Hare doe than the first-prize winner in the above class; the second a fair Silver-Grey, and third a Black-and-white Dutch. In Selling class for Lops the first was a Fawn-and-white buck, 21 inches by 4½; second, Black-and-white, 20 inches by 4¼; third, Fawn, 20 inches by 4⅜. In the Local class was first a Fawn buck, 21½ inches by 4⅞; second Angora, and third Dutch.

Mr. Hutton judged the Rabbits and Pouter Pigeons.

CRYSTAL PALACE BIRD SHOW.—No. 2.

DELIGHTFUL as were the Canaries, equally so were the Mules and those birds in the other portion of the Exhibition. I always had a very great fancy for Mule birds, and my curiosity was much appeased after going through them and admiring the beauty and respective qualifications of the prize-winners. There is something exceedingly smart and aristocratic about Mule birds, more particularly in those bred betwixt Goldfinches and Canaries. One cannot fail to become ardent admirers of them, close as they are in plumage, and so very vivacious and amusing in their ways compared to Canaries. Some were faultlessly marked and pencilled about their eyes and smaller flights, and others nearly clear, throwing up that splendid Goldfinch flush around their faces and on their wing-bars and breasts, that each bird with its delicate lovely garb and ancestral form brought to mind the words of our poet laureate—

"Half is his, and half is thine; it will be worthy of the two."

Mr. James Doel of Stonehouse, Plymouth, was the fortunate possessor of many of the prizetakers, he having won ten prizes out of the eighteen the Judges awarded, thus becoming the winner of the silver cup offered (in classes 30 to 33 inclusive), to the exhibitor gaining the greatest number of points. Mr. Doel took first and second and extra third in three of the classes (30, 31, and 32), and first, third, and extra third in class 33. The whole of his birds were in fine condition, and were sent to the Show wonderfully clean considering the distance they had travelled. In class 30 Mr. Hawman's Evenly-marked Yellow played a good third to Mr. Doel's pair. In classes 31 and 32 the chief competitors to Mr. Doel were Messrs. Bunting, Stevens, Caplin, and Tomlin. Class 33, which was justly specified a "very good class," contained some birds very nearly clear. Had they been clear it was stated that special prizes would be awarded, but they were not, and so they had to go without. The two nearest approaching to clear were those numbered 776 and 778, exhibited by the Messrs. E. & J. Baxter and Mr. S. Bunting, the former exhibitors' specimens being marked very distinctly but slightly about each eye, and the other slightly grizzled upon one of the flight feathers: two superb birds. By some slight error the equal second-prize ticket was placed upon Mr. Boatwright's cage instead of Mr. Bunting's. This, however, was rectified during the second day of the Show.

The Mules were continued with a couple of classes for Dark Mules (Jonque and Mealy), a class for Linnet Mules, and one for Any other variety of Canary Mule. In these four classes there were sixty specimens, but the more interesting ones were those exhibited in classes 36 and 37. The Dark Jonques must have been a troublesome lot, for I could not see very much difference betwixt the first three or four birds, still I think Mr. Hawman's bird was rightly placed. In the Mealy class Mr. Cox won first with a fine-made bird full of quality, Messrs. Bunting and Moore & Wynn following well up with birds far beyond a middling quality. Mr. Spence took first and second for Linnet Mules, Mr. Stevens being third. I have seen a better class than this, the birds not being quite up to my expectations. In class 37 Mr. Hawman's Greenfinch and Canary Mule appeared to be at home; it is a fine bird and will take a lot of beating. Mr. Alwin's second-prize bird was in good plumage; and the third prize, a very prettily pied Siskin and Canary Mule, was won by the Messrs. Baxter.

Betwixt the Mule classes and British birds the cages of sixes were shown. Eight sixes of Norwich of varied sorts were entered, the best of the lot being the six in spanking plumage exhibited by Mrs. Maria Judd of Newington Causeway. Messrs. Mackley, Norwich, were second, third, and extra third—three good lots. There were but three Lizard sixes, and not much difference betwixt either. First was given to 849 (Fairbrass); second Bunting, and third Cleminson & Ellerton. The sixes for Goldfinch and Canary Mules only reached two entries, and one prize only was given, that to Mr. Doel's cage, which contained half a dozen birds fit to compete with singly.

Class 41, Miscellaneous, for any other variety of Finch Mules. In this class several entries were made in error—namely, a Black Mule, a couple between Siskin and Canary, Linnet and Green bird, and five Cinnamon Mules. The class was judged as they stood, and a second prize was given to Mr. Doel's Black Mule, but another exhibitor raising an objection the bird was withdrawn. The first prize was awarded to Mr. John Brown's Bullfinch and Goldfinch cross, a bonny specimen. The appearance of several of the cages in this class was somewhat marred through being partly covered with printed papers denoting the respective breeds of the occupants. Why they should have been made so conspicuous I am at a loss to know. The particulars in the catalogue ought to have sufficed.

The classes for British birds were well supported. Bullfinches numbered thirty-one, Goldfinches forty-nine, Chaffinches ten, Linnets eleven, Redpoles and Siskins eight, Skylarks sixteen, Robins thirteen, Thrushes twelve, Starlings nine, one Magpie, one Jay, three Jackdaws, and nineteen of various other breeds in class 55. Those of especial merit were Major Edwards's Bullfinch; Messrs. Doel's and Hawman's Goldfinches, the former in particular an exceptional good one; Mr. T. Alwin's Chaffinch; Messrs. Cannon's and Cleminson & Ellerton's Brown Linnets; Mr. Newmarch's Siskin; Mrs. Judd's Skylark; Mr. Cox's Robin; Mr. R. J. Troake's Blackbird; Mr. Newbold's famous Thrush (one of the best plumed in the British classes), and Miss Emma Hawkins's two very learned Starlings, one of which was stated to whistle an air from "Madame Angot."

In class 55—Any other variety of British birds—a White Goldfinch belonging to Mr. Allcorn, headed the lot for honours which were freely given. Miss Norah Mohr and Mr. John Young had equal firsts awarded, the former two prizes for a couple of pairs of smart Bearded Tits, and a cage containing a Grey or Dun Wagtail Blue. Mr. Young's equal first was won with a very good feathered Nuthatch.

Birds of Passage formed three classes, half a dozen Blackcaps making up the class, Mr. C. Varetti being the winner of first and second prizes. There were six Nightingales, Mr. O. A. Watts being foremost with an interesting bird, which occasionally treated the visitors with its vocal power. The other class was represented with a Cuckoo, a Titlark, a Yellow Wagtail, and a lesser Whitethroat. Mr. Tilney's Wagtail was to the front; Mr. Walker's Titmouse and Mr. Watts's Whitethroat equal seconds.

Foreign birds were likewise numerous, and besides those entered in the classes was a splendid collection exhibited by A. F. Wiener, Esq., Belle Vue House, Herne Hill, Dulwich, comprising thirty-one birds of various breeds. Although not for sale or competition they did not escape the notice of the Judges. Altogether there were eighteen classes for Foreign birds, and there were 147 entries, consisting of Widah Birds, Red-headed Cardinals, Virginian Nightingales, Waxbills, Java Sparrows, Diamond Sparrows, Doves, Love Birds, Parakeets, Cockateals, Parrots, and Cockatoos of various kinds, besides a large entry in the last class for Foreign birds of any other variety, "too numerous to particularise," as an auctioneer would say.

The Selling class and the class for exhibition cages terminated by far the finest show of Cage Birds ever held.—An Eye-witness.

SQUIRRELS ARE EGG-SUCKERS.

In your notice to correspondents, page 206, you write, "Squirrels do not suck Rooks' or Partridges' eggs." Perhaps not; I do not know, but I do know that they suck Woodpigeons' eggs, having seen them do it. I was induced to watch by finding frequently at the foot of fir trees on which the Woodpigeons nested egg shells empty, with au opening on the side about the size of a shilling, jagged as if made by the teeth of some rodent.—R. F. F.

Bath and West of England Society and Southern Counties Association.—Croydon Meeting, 1875.—The General Post-office will extend the telegraph wires to the Show Ground, and make such other arrangements as may be desirable. For the Meeting of 1876 the Council have accepted the Hereford invitation.

LIGURIAN AND COMMON BEES.

Some fourteen days ago the desirability of having a public trial of strength between Ligurian and common bees was suggested. It was hoped that some one would propose a few simple rules and regulations to be observed in a trial of this kind. I now venture to state what I think would be a fair and satisfactory way of testing whether Ligurians are in any sense better than common bees. Five swarms of each sort, all equal in weight, say 5 lbs. each swarm, put into hives alike in size and materials, placed in one garden at the same time, and remain together till examined and weighed by the judges. Of course the hives would be placed under the care of an honourable person, and never be visited by their owners. If a more satisfactory trial can be suggested I shall be very glad.

Thomas Bagshaw, Esq., of Langnor, called here the other day, and as he is a young, energetic, and intelligent apiarian, and better able than myself to undertake the activities of the proposed contest, I am glad to say that he is ready to make arrangements for a public trial. His bees are the common sort, and if he has not swarms enough at the time that may be fixed on I will gladly lend him some of mine.

I shall be gratified if any gentleman, or number of gentlemen jointly, will arrange to produce five swarms of Ligurians wherewith to enter the arena to meet those of Mr. Bagshaw. If five swarms of hybrids be entered as well the experiment would have a wider sweep and be much more important. Shall we not indulge the hope that the admirers and patrons of Ligurian bees will now embrace this opportunity of proving the truth of their assertions as to the superiority of their favourites?

If the projected trial establish or prove the superiority of Ligurians all right-minded apiarians will encourage their propagation and sale all over the country; and if they are not better in any sense poor people will be instructed not to expect greater results from Ligurians than are realised by common bees. In such a contest there is nothing to fear. Though I believe now that the common bees are inferior to none in their breeding and working powers, I shall be delighted to see them fairly beaten.

If a contest cannot be arranged without stakes and prizes, let me say that, if any of the patrons of Ligurians will intimate their willingness to enter the arena of contest on condition that a handsome prize be given to the winner, the best shall be done to raise subscriptions to cover a fair share of the prize-money.

If our friends wish to convince the bee-keepers of Great Britian that the common bees are inferior to theirs, they have now an opportunity offered to them of doing so. And if they come forward in an honest manly way to have this matter settled, they will do something to advance apiarian science and benefit the bee-loving community.—A. Pettigrew.

A VISIT TO HANWELL.

Not to the Asylum, although some would perhaps say I was mad enough over flowers to be qualified for it; not to the Central Schools, although I did go there, and should be quite prepared to take the defendant's side in "Senior *v.* Tufnell;" but to the Editor of the "Bee Journal," the well-known Hanwell beemaster, Mr. Charles Abbott: for amongst my cultures I have for many years, in a bungling sort of way, kept the little busy things. But I have been very much dissatisfied with my keeping. I had built a bee house, into which the wax moth had come and destroyed two of my best hives, and which I had demolished accordingly. I have long thought that if I kept bees at all it should be in not quite so unscientific a way as I had done; and this feeling was intensified by seeing the wonderful Exhibition at the Crystal Palace last year, and hearing, and indeed beholding, the amazing results produced by bee-keepers in various parts of the kingdom, more especially in Scotland. And so, as business led me to Hanwell, I determined to utilise the visit for this purpose; and having corresponded with Mr. Abbott felt sure, from the tone of his letters, that I should be received with courtesy and initiated into everything that I as a novice might require information upon. There were some three or four things I wished to get evidence upon:—1st, What sort of hives were the best, wood or straw; 2nd, whether the use of the quilt was advisable or not; and 3rd, the value or otherwise of the Ligurian bees.

I found, as I have often done with the most successful growers of flowers, that the place where Mr. Abbott "cultivates" his favourites was not at all a likely place to look for them. There was no fine and open space, no fragrant dell or brilliant parterre, but I turned into a small cottage yard in the street of the long straggling village of Hanwell; and there, in a small square back garden, were in all directions hives of all sorts, and here have the experiments been made which have been recorded in the "Bee Journal," and which, while they have produced so much controversy, have also led to such good practical results.

And now as to the question of hives. Of course now-a-days nothing but bar hives will do; but the question is, What sort of bar hives shall they be—of straw or wood? and if of wood which is the best? The wooden bar hives are all more or less a modification of the old Woodbury hive; and as I am not inviting a buzz about my ears, and probably a sting or two into the bargain—(for writers on bees seem sometimes as if they had stolen some of the poison bags of their little pets and dipped their pens in them)—by disparaging this or that hive, I am only going to say what I saw that pleased me. There was first of all the wonderfully cheap Woodbury that gained the prize at the Crystal Palace, and which is made for 3*s.*: this ought to be largely used for the purpose of trying to induce our cottagers to give up their barbarous practice of destroying the bees. Then there was Mr. Abbott's own hive, which struck me as being a most admirable one, and which is made for 25*s.* complete, or with some further improvements for 35*s.* This hive seems to me to have all the advantages of a Woodbury, and to be superior to it in some

points which it will hardly be necessary for me to enter upon here. So bigbly did I think of it that I am going to have one for my new start in bees this year.

And now as to the quilt. I have seen some very hard things said against it, while others have been equally loud in its praise. Now I examined several hives here, and I saw no trace whatever of the damp which is said to be engendered by it. The corners of the hives were perfectly dry, and there if anywhere damp would collect. I had, too, an opportunity of contrasting it with the ordinary board covering. A hive had been sent to Mr. Abbott in which the combs were all crooked, and which he was going to straighten. This had not been opened; and so, as there was a gleam of sunshine, he opened it in my presence. A great deal of damp had collected on the floorboard and on the crowns: so that on this point, therefore, I was quite satisfied. And then in the facility which it affords for examining the bees I think there is a great advantage: there is no unscrewing of boards, but by just simply lifting up the piece of carpet you have a complete command of the hive. So here again my visit had the effect of determining me to adopt the quilt—which, by-the-by, is a queer name to give it, for it is in reality simply a tidy square of carpet. You can of course put anything else on this for warmth, and either cover with a board or the old cottagers' plan of an inverted pan.

And now with regard to Ligurians. It would ill become one who is a novice to enter into any dispute on this point, or to decide between Mr. Pettigrew, who I see has strongly decried them, and others who approve of them; and yet I gather from his letter that greater results have been obtained from them than from the Britishers. There is one advantage they possess—they are so much more gentle, and to timid bee-keepers this is an advantage not to be despised; and from what I could see with Mr. Abbott I should decidedly give a vote in their favour. They are also very pretty, but I do not think my decision was influenced by the "prisoner at the bar being of a very prepossessing appearance."

There is no doubt that bee-keeping is entering on a new phase in England. We have had stores which we have wasted, and continued practices which are barbarous and wasteful; but care must be taken that we do not go to the other extreme by over-refinement. Bee palaces such as I saw at the Crystal Palace are, I think, abominations; and if this is avoided and a kindly and teaching spirit manifested by those who are adepts, I am sure great benefit to the community at large will be the result, and amongst those who are helping to this end we may safely reckon Mr. Abbott and his "Bee Journal."—D., *Deal.*

OUR LETTER BOX.

Chickens Weak (*Miss Evelyn*).—Breed, food, and their day home should all tend to make your chickens strong; but your arrangement for them at night is a very bad one. Young chickens should never be on straw. Nothing could be better than the dry earth of the barn floor and an old sack thrown over the coop. The chickens of the cross grow very fast—indeed often too fast for their strength, and then appears the leg-weakness you mention, which can only be cured by a good diet of easily digested natural food. We should for young chickens feed entirely without meat, substitute fine meal rubbed with bread crumbs and chopped onion for the grits, and keep on with the bread and beer.

Henhouse and Yard (*Edith A.*).—Your very good sketch is the design of a very good miniature run and house. The red line partition is not necessary. Where you have but little space to spare the laying house must form part of the roosting house of your birds, and the nests would do well as you have drawn them. If made in blocks and moveable so much the better. Your carpenter would make the lean-to and put on the felt, and any of our wire-workers, on being furnished with a scale of measurement, would make you panels of galvanised frames to meet exactly your requirements.

Canaries and Cayenne Pepper (*Curioso*).—Canaries are made high-coloured with the free use of cayenne pepper in their food. Some breeders mix it with egg and biscuit; others use it in a cake with which they freely feed the birds the whole of the moulting period. To one egg, when hard boiled and chopped fine (or it may be more effectually done by pressing through a sieve), add two teaspoonfuls of cayenne pure and mixed well together. Then add one small biscuit reduced to a powder. Mix the three ingredients together and supply your (say some half-dozen) birds with the diet two or three times daily. No green food during the moult. The more of the pepper food the birds partake of, and the less of seeds, the deeper the colour of the plumage will be. You need not fear your birds feeding upon the above food. Commence with the pepper diet when the young have attained the age of six weeks. There will be no necessity to put the whole of the young birds upon the cayenne diet. Select for the purpose the boldest and most likely-looking cock birds. Young Canaries bred from pepper-fed birds will not be high-coloured in first or nest feathers. To make them high-coloured they must be moulted upon cayenne.

Kedlock Seed (*Constant Reader*).—See Journal of last week for advertisement announcing the sale of Kedlock seed.

Stimulating Food for Canaries (*Subscriber*).—Any extra diet or food (beyond the usual supply of canary, hemp, millet, rape, and flax), such as egg and biscuit, with a pinch of pepper in it, dandelion, small salad, cress seed, German paste, or a little biscuit slightly soaked with sherry wine, or a few drops in the fountain, will each and all tend to prepare or stimulate Canaries for breeding purposes.

Driving Bees (*W. W.*).—Without seeing your hive it is difficult to decide whether the bees should be allowed to remain in the top hive or be driven into the bottom one. As the combs in the top hive are very old and the bees hung out in clusters for weeks last year without swarming, it is preamnable that they may not swarm or do better this year if not treated differently. Take or part the hives asunder and examine both. If the combs in the nadir are chiefly composed of worker cells (not much drone comb) we would drive the bees from the hive of black combs into the other, and feed them twice or thrice a-week for a month. If the combs in the nadir are chiefly of the drone kind better let the bees remain amongst the old combs, and swarm them artificially when the hive becomes full. It would not be safe to put the bees into an empty hive at this season.

Hives (*W. R. F.*).—Write to Mr. Pettigrew, Priory Vineyard, Sale, Cheshire.

Two Hives of Bees (*Triceps*).—You want to know how best to manage your two strong hives, so as to get one swarm out of them and no more, but plenty of honey. We advise you to drive the strongest of them into a new hive about the second week in May, or as soon as they begin to hang out. Put the new swarm so driven in its new hive in place of the parent hive out of which they were driven. Be sure you drive out or otherwise dislodge every full-grown bee, so as to make the swarm as large as possible. Having thoroughly emptied of its bees the old stock, put this over your other strong stock, taking care to open the communication between the two hives. The bees from below will ascend into the empty driven stock, and after hatching out all the young bees will proceed to fill the cells with honey as fast as they become vacant. The fresher the comb in the supered stock the finer will be the honey stored there. The swarm in a good season and a good locality ought to give you some honey too.

REMARKS.

10th.—White frost in morning; very bright and nearly cloudless day; overcast in evening.

11th.—Another bright day, with bitterly cold wind and rather more cloud.

12th.—Very dull day, with bitterly cold wind and overcast sky.

13th.—A similar day; but warmer in the evening, and a few drops of rain.

14th.—Overcast early, but brighter after noon, wind still very cold.

15th.—Cloudy morning, but sunny afterwards; sky nearly clear at night. Lunar halo.

16th.—Overcast the greater part of the day; a fog, like a November one, but not so dense, came up suddenly at 5.30 P.M., and lasted the rest of the evening.

A cold parching week.—G. J. Symons.

COVENT GARDEN MARKET.—March 17.

There is not anything fresh to report, business being generally very quiet both at home and provincially.

From observations taken near London during forty-three years, the average day temperature of the week is 52.9°; and its night temperature 33·6°.

SHANKING: ITS CAUSE AND CURE.

SHANKING, like many other so-called diseases, is not a disease at all, it is merely a reminder—and not always a gentle one—on the part of Nature that we do not understand her teachings. I believe outdoor Grapes do not often shank, and we know they do not always have the most skilful treatment, but put a glass covering over them and they are at once liable to shanking, imperfect setting, and all sorts of bad behaviour. Why is this? Why should they, like most recipients of charity among the genus homo, behave badly in proportion to the amount of kindness lavished on them? Similar cases occur with many other plants besides Vines; they do tolerably well left to themselves, but immediately they are nursed their constitution seems impaired, and they require all sorts of indulgences.

The reason is, we only possess a partial knowledge of the plant's requirements. We perhaps understand perfectly what is required above ground to produce vigorous growth, and even tolerably well-ripened wood, and flatter ourselves that all must be right, and picture in our mind's eye the well-finished Grapes we shall have to astonish our friends with in the coming summer.

This illusion is kept up through the greater part of the following season of growth; the Vines break regularly and strongly; they show three times as many bunches as are required; they set well, if they are Hamburghs or Sweetwaters, and swell rapidly; they commence colouring. All must be right this time; but no, many of the berries which should turn blue-black turn to a very ugly red, and never ripen at all.

On examination it will be found that the stalks of such berries have shrivelled and ceased to perform their functions. Sometimes the shanking will be visible before this time, and occasionally it is delayed until the berries colour tolerably well, but they will not become sweet; yet at whatever stage it is visible chronic cases always occur from the same cause—viz., insufficient root action in proportion to the growth at the top during the early part of the season.

There may be slight temporary cases resulting from overcropping, denuding the plants of foliage or from insufficient watering, but the progress of shanking is then easily arrested by a change of treatment. On the other hand, let the roots of a Vine be in a cold outside border, and its head comfortably housed in an average temperature of 70° during the cold spring months, nothing on earth will prevent its fruit shanking after a few years of such treatment.

I am aware that most people who have to produce early fruit from Vines which have their roots outside protess to cover their borders, but are they always sure the principal roots are under the covering? They may be a hundred yards away.

Shanking also occurs on Vines which have their roots wholly inside the house, and even on those which are unforced: can it then be said to arise from the same cause? Most assuredly. The Vine is like no other plant with which I am acquainted, for it makes considerable growth at the top, and even forms full-sized leaves, before it commences to root; and in the case of small cut-down plants which are only allowed to make one shoot, the said shoot grows from 9 to 18 inches in length before a single rootlet begins to move; the length of such growth depends mainly on the temperature in which it is made.

If, then, it is clear that this growth is made from the stored-up sap and the stored-up sap is limited, there is no advantage in distributing it over 18 inches of growth instead of confining it to 9 inches. For this reason I prefer the growth to move as slowly as is consistent with healthy growth till the roots commence action, and as I know there must be a certain amount of foliage before the roots can commence, I never disbud till the leaves assume a darker green and plainly tell that they have a new supply of nourishment. The growth made after this will be more solid, and when ripened the wood will be round and contain but little pith, instead of being flat, as it often is on young Vines which have been cut down.

I have alluded to young cut-down Vines to make my meaning clear. In the case of older Vines making numerous growths it is very similar, only the growths from being numerous are not so long. They also come into full leaf before root-action commences, and the length of growth thus made also mainly depends on atmospheric conditions. The embryo bunch is already formed in the plump bud of the previous year; its supply of nourishment till such time as root-action commences is limited, a high temperature as soon as the buds have started will bring it out quicker than a medium one, and the bunch will also look larger. This deceptive appearance is owing to the flower stalks being longer than they should be; instead of being a quarter of an inch they are, perhaps, three-eighths long, and of course weak in proportion.

They will never recover this, and though they may grow luxuriantly till colouring time, they will most assuredly shank. It must not be thought that the length and strength of the flower stalks are determined after these are visible, it is much earlier than this that the mischief is done, although continued ill-treatment may aggravate it.

If my readers will agree with me as to the cause of shanking, the cure will suggest itself—viz., a healthy medium for the roots and a moderate temperature till the flowers are set. They will probably find this cure for shanking also a cure for bad setting. 55° is the minimum atmospheric temperature aimed at for all Vines, including Muscats, till the flowers are set; 5° lower occasionally will do them no harm at any time. After they are set they will bear almost anything short of roasting. My earliest Grapes are produced on pot Vines, for which the atmospheric temperature is about the same as that given above, but they have a bottom heat of 80° to 95°.

If the roots of a Vine are in a greenhouse, the border is often covered with plants all through the spring months

so that not a ray of light can reach it. Roots so situated are probably in a lower temperature, and altogether worse off than they would be in an outside border.—William Taylor.

ROSES.

"Our Journal" without some Rose notes is to me always like the play of Hamlet without the prince, and of late, somehow, this melancholy arrangement has been in vogue. "How to grow them and how to show them" is a theme which will defy exhaustion, even at the hands of those reverend amateurs whose Rose knowledge of which we have now and then such pleasant glimpses.

Reviewing the Rose contributions during the past year, nothing, it seems to me, has appeared having more practical value to a large section of Rose-growers than the published election lists so carefully collected and summarised by Mr. Hinton. Nothing is more bewildering to a novice, or to one whose limited leisure, means, or space precludes his growing more than a few varieties, than to wade through the pages of a nurseryman's list, where the glowing adjectives vie with the flowers they are supposed to describe, driving him at last to feel that "Cæsar and Pompey are very much alike, especially Pompey." After Mr. Hinton's yearly lists have been fairly compared such an amateur need be under no difficulty in selecting a reasonable number of what ought to turn out satisfactory kinds, and this is a real gain.

Shows are somewhat fallacious standards, as to a tenant farmer on a poor estate is a high-pressure lot of shorthorns from the herds of titled breeders at the "Royal" as a guide for what stock he had better invest in.

The best collection of cut blooms I had the chance of examining last year was at the Exeter Show held the 3rd July; and as an example it will doubtless be remembered by some who were there, at least by the Rev. Mr. Camm with whom I had the pleasure of a short gossip over the boxes, that a bloom of Centifolia Rosea, shown by Paul I think, was one of the finest Roses in the Show. This of course could only be looked on as a fluke, and so a bad guide to buy from. It is nowhere in the election list for the best fifty.

But no Show has ever yet surprised me as do the lists of the Rev. Mr. Radclyffe which frequently appear. I have hardly ever been able to verify his recommendations by experience. On the 20th August "C. P. P." and the Rev. Mr. Camm specify objections to the Roses named by him and demur to his omitting certain well-known high-class varieties, and I am at one with them in what they have said. As to Felix Genero, I have not only never succeeded in growing a decent flower from this Rose, but I have never found anyone else that had. And Madame Margottin is probably the last Tea Rose I should recommend: it is as ragged as a Falstaff recruit. I should really like to know Mr. Radclyffe's secret for growing satisfactorily Edward Morren. I have, moved by his eulogies, done my best with it on the Manetti and on the Briar, but it will open badly; and if two or three blooms in a season condescend to expand, they are so loosely made and so susceptible of being spoiled by sun, wet, or wind, that I should class it as one of the most unpromising Roses for the amateur who cannot afford to run a race of experimental selection.

On the 13th August he says, "I specially recommend to persons liking dark Roses Louis Van Houtte, Baron Chaurand, Maxime de la Rocheterie, and Baron de Bonstettin." He omits from his *general* list of desirable Roses La France and Marie Baumann because of their weak growth. The fact with me is that both these Roses are more robust and free-blooming than Louis V. Houtte; and in "our Journal" of the 24th September there appears an election list made in the north, which shows that even there both these Roses stand amongst the highest. Now take Prince Camille de Rohan, a Rose I have never known him recommend. It was in every show stand of general collections in Exeter; and my proof of it is that, all points considered, it has no superior as a dark Rose; and for vigour simply—Mr. Radclyffe's great point—it is difficult to find an equal.

I am somewhat surprised to find Mdlle. Marie Rady does not have a better place in the election lists. As a late bloomer especially it is an admirable Rose; and take the season through, on the Manetti it gives as many perfect blooms and such substance in them as any I could name. It would be included by me in the best twelve.

Marquise de Castellane by the voting has retrograded this year. This I think is only temporary. It is fine in colour, vigorous in habit, and free-blooming; and I believe the ordinary grower will not regret having it in his collection.

Etienne Levet has had a successful year and bids fair to be a good Rose; but I have found François Michelon so far to run thin. Of Madame Lacharme's shortcomings I can endorse all the bad things Mr. Beachey and others have said about her. Comtesse d'Oxford, both on Briar and Manetti, retrograded with me in 1874; it has the knack of fading rapidly, which is not in its favour. Lyonnais is a good Rose. Mdlle. Eugénie Verdier though shy is worth trouble.

The old veterans hold their own in the far west. Alfred Colomb, Charles Lefebvre, Duke of Edinburgh, Baronne de Rothschild, Camille Bernardin, Souvenir de la Malmaison (specially valuable in autumn), John Hopper, Pierre Notting, Marguerite de St. Amand, Jules Margottin, Général Jacqueminot, Abel Grand, and Fisher Holmes. Nevertheless, after admitting to the full all the glories of the Perpetuals, I quite share Mr. Camm's enthusiasm for Teas: they are the true Perpetuals.

What after all can be, not only more lovely but more certain as a matter of culture over a large part of England, than the "oceans of blooms" a good collection of Tea Roses fairly attended to will give?

Take trellised lines of Gloire de Dijon, Souvenir d'un Ami, Safrano, Catherine Mermet, Madame Willermoz, Souvenir de David, Marie Van Houtte, Madame Falcot, Devoniensis, Adrienne Christophle, Canary, Homère, Vicomtesse de Cazes, Rubens, Madame Bravy, Perfection de Montplaiser, with their half-sisters Triomphe de Rennes, Lamarque, and Celine Forestier leading from and to these, "through many a bowery turn," of wire or wood arcades with blooms of Rêve d'Or in profusion mingling with Clematises Jackmani, Prince of Wales, or others of that ilk; and if a bit of wall can be had cover it with Maréchal Niel, Climbing Devoniensis, Perfection de Lyon, and the Banksians. What a feast for the senses! One need not be morbidly poetic for the radiance of such a sight heralded by the gentle air "full fed with perfume," to recall to his mind that bower whose

> "Flowery roof showered Roses
> Which the morn repaired;"

or that pavement

> "That like a sea of jasper shone
> Impurpled with celestial Roses, smiled."

To those who lead busy lives in these busy times I recommend such pleasures; they will find in their refining influence a fit counterpoise to the tenor of their daily occupation. If on trying it anyone should fail to find this relief in the hobby of Rose-growing their case is a bad one; and I do not think they can do better than seek out the "Wiltshire Rector," "open their grief," and seek of him the secret of that alchemy by which genuine pleasure and a healthy mind are to be derived from natural objects and harmless tastes.—Cornubia.

PEACH FORCING.—No. 2.

Borders.—These as shown in the sections, pages 69, 70, and 71 of the present volume of this Journal, are within and outside the house. Inside borders should extend the whole width of the house if there are trees against the wall as well as against the front trellis. The outside border should at least be equal in width to half that of the trellis to which the front trees are trained. In any case the border should be of the same width as the trellis the trees are to cover. For early forcing the principal border should be inside, whilst for those not started until a later period the main of the border may be exterior. Why I prefer part outside to all inside is that the former is always certain to be thoroughly moistened by the autumn and winter rains, and the roots in it are always capable of meeting any demand upon them for moisture by the head when the wood is ripening and the trees are at rest. This is more than can be said of inside borders, and over-dryness of the roots at that time is one of the chief causes of the buds dropping.

There is no fear of the roots in an outside border suffering any injury from frost, for, though the Peach be an exotic and tender, the Plum upon which it is worked is very hardy, surviving the severest weather uninjured, even when the surface soil is matted by its fibres. I do not, however, advise leaving them exposed to hard frost, but insist upon a few inches' thickness of short littery dung and leaves being placed on the border when forcing is begun, and that serves every needful purpose of protection for the roots.

Deep borders have been advised, but I do not see the utility

of them, for the Plum is a surface-rooter, and does not descend beyond a depth of 2 to 2½ feet. Everything is gained by a border 3½ feet deep, and of this 9 inches will be taken up by drainage, leaving 2¾-feet depth for compost. Beneath the drainage should be drains 9 to 12 feet apart, having proper fall and outlet.

Soil.—Though the Plum succeeds best in rather light soil, it is not the case with the Peach upon it. In poor light soil growth is weak, and the fruit correspondingly poor in quality; whilst if light soil is made rich the wood produced is slender though long, and wood rather than fruit buds result. Soil most suitable for the Peach is a medium-textured loam, neither sandy nor clayey, and if of a calcareous nature all the better. The soil, known as yellow or hazel loam, taken from a pasture, the top 3 inches, chopping it up in squares of about 2 inches, and to this add a fourth part of marl—that known as chalk-marl is most desirable for soil of the above description—the shell-marl, being very little, if at all, inferior, is a good compost. For sandy loam clay-marl is a beneficial addition; whilst for a heavy loam sandy-marl is good, in both cases adding the respective marls in proportion of one-fourth of the loams. An admixture of chalk we advise in every instance, excepting, of course, with soils of that formation. This should form one-eighth of the compost, and should be broken up moderately small, say in sizes from a hazel nut to an egg. Flint (silica) also broken up, or better crushed in a pugmill, in the same quantity as the chalk, is a welcome addition to a compost for the Peach, and, in fact, all stone fruits. The whole to be well mixed and be in a moderately dry state when used. On no account must the border be made with the compost in a wet condition.

I recommend the above mixture because the best trees and finest fruit I ever saw under glass were produced by such compost; at the same time I am aware that good fruit has been grown in plain loam. Those who cannot well procure the ingredients named above I advise them to mix with the loam one-fifth of cow dung and a sixth of old mortar rubbish. The materials to compose the border should be put firmly together, and it is hardly necessary to say that the lighter the compost the greater necessity for solidification, and the more adhesive the materials the less need is there to make firm. A light soil should be made hard and all firm.

Selection of Trees.—For very early forcing it has been recommended to have the trees in pots as pyramids, bushes, or standards. I can vouch for their answering well, the pots being about half plunged in a border of good rich soil the roots leave the pots and have extra feeding ground. Such trees are, however, more trouble in watering, and require very liberal treatment in top-dressings, and liquid manure if the fruit is expected to equal in size that of trees in borders. They also answer very well when the pots are not plunged, but the watering requires to be more frequent, and the feeding must be high. The trees should be of a fruiting size, and the growth ripened-off early in the previous year if the fruit is to be ripened early in the year following.

For starting early in December the trees should have the wood ripe in September, and may be plunged outdoors in a sheltered yet open situation. Trees so exposed suffer no damage, but are, I think, every way benefited. Not a bud drops, and they swell the buds more regularly than those kept inside; they start into growth sooner, and appear to be thorough cleansed of insects.

It will not be needful to make any extended remarks on the trees which are to be planted out; they should be of fruiting size, having been two or three years trained against a wall, and have a good extent of head to begin with, with some prospect of fruit the first season. The trees chosen should be well furnished, and it is better they be moderately strong, yet by no means having long luxuriant growths, as these receive too great a check in removal, and often lose some of the branches by gumming.

The mode of training the trees should be on is that known as the fan, selecting such trees as have evenly-balanced heads, clean healthy bark, and stiff, short-jointed, well-ripened wood. If young trees are planted they will require at least a year before they come into bearing, and ought not to be allowed to bear heavily the first two or three fruiting years. All this, however, is best avoided by planting fruiting trees in the first instance, such as will cover at least a third of their allotted space at once. There is no risk of the trees receiving any great check from removal if the work be done carefully, for the Plum is the best of stocks to lift with a mass of fibres.

I may say just a word in favour of bushes, pyramids, and standard trees planted out. They are no more trouble in watering than fan-trained trees, and a span-roofed house will accommodate them admirably. In this way it is more natural than training them flat to a trellis, and they answer quite as well, only for very early forcing the shoots are best near the glass; and as some of the parts of the bushes and pyramids must be at a considerable distance from it, they do not receive so much light as the upper part of the trees, consequently the growth and fruit there is not equal to that nearer the glass.

Sorts.—*Royal George.*—This is the best of all for early forcing, being a certain setter, a sure sweller, and ripening off well. Whatever the weather—sun or no sun, this kind invariably sets well, and is unquestionably the very best forcing kind.

Grosse Mignonne.—This I consider the next best forcing Peach, being a first-rate setting kind, swelling kindly, and ripening off perfectly. The fruit is larger than Royal George, and comes in a few days later.

Noblesse.—A free setter, but the fruit does not swell so kindly as Royal George or Grosse Mignonne, but is nevertheless one of the best forcing kinds, and the three aforenamed I consider the three best kinds for early forcing.

Violette Hâtive is a good setter and excellent kind for forcing. It ripens a few days later than Grosse Mignonne.

Barrington sets well, and is every way desirable, being a little later than Noblesse.

Bellegarde sets freely, but the flowers do not open well in sunless weather. It is a grand Peach, yet I do not recommend it, Barrington, or Violette Hâtive for early forcing, but all are excellent for starting after the new year.

I have omitted Early Beatrice and Early Louise (the latter only a few days later in ripening than the former), because they are an entirely new race, and one certain to upset our notions of early Peaches. The fruit of these is of fair size, but their merit is their earliness, ripening five to six weeks before Royal George in the same house. Early Louise is the better fruit, and both are very desirable.

With these we recommend the earliest house to be planted, the second with the three first-named, and any or all of the six first-named for the third house, and each house to be taken at a month's supply, though it will usually be longer continued.

Early York and Early Grosse Mignonne with others I do not recommend, as they do not either set well, or the fruit drops after setting. Almost any kind answers if not started until after February; but some kinds evidently have great aptitude to make wood when under the influence of high and continued artificial heat, and usually, though promising well, disappoint in the end.

Nectarines.—Stanwick Elruge, a few days earlier in ripening than the Elruge, is a capital setter. It is a very desirable forcing kind.

Lord Napier sets well, and is the earliest and best for early forcing.

Elruge is a good setter, even in dull weather, and one of the best kinds. It is desirable to associate it and Stanwick Elruge with Royal George, Noblesse, and Grosse Mignonne Peaches; whilst Lord Napier is suitable for the same house as Early Beatrice and Louise Peaches.

Pitmaston Orange and Rivers' Orange Nectarines are both free-bearers, and those with Elruge we recommend for the second house, as is also Stanwick Elruge. For the third house any of the four last-named and Violette Hâtive, Pine Apple, Victoria, and Albert Victor, the three last having large fruit, and are most excellent.

The above are all good kinds for their purpose, and will not disappoint.—G. Abbey.

GERANIUMS FOR BEDDING.

Now that the season is at hand for potting the above (where they have been wintered in their cutting boxes) many will be at a loss to find pots for that purpose, when thousands are required; and if potted, at a greater loss to find a suitable place in which to put them. As we are among that numerous class who have a great deal to do with comparatively little means and accommodation, I will just detail our usual practice with Geraniums.

The cuttings are struck in the usual cutting boxes, and wintered in any suitable place. About this time, the beginning of March, the plants are taken carefully out of the boxes with a hand fork, a little tough sod is then wrapped around

the roots, and tied with any handy material. We use the leaves of the New Zealand Flax, the fibre of which is very strong, a leaf being sufficient to tie three or four dozen plants. Since the Russian mats have become so expensive we have turned the leaves of this highly-ornamental plant to many useful purposes. I fancy I hear many of your readers say, What a pity to destroy this plant for tying Geraniums; but we have it growing here by thousands in the wildest profusion, and consequently have plenty to use.

I fear I am digressing. I will now return to the sodding, as we term it. This is capital employment for the outside men in inclement weather (I am no advocate for keeping men out when it is wet). When we have not had turf at command we use moss, with a handful of fresh soil around the roots. They are then planted out on a slight hotbed of leaves in pits or frames. When removed to their summer quarters the balls are a mass of roots, and can be planted with the greatest safety.

By adopting the above plan much time is saved in watering, and they start into growth and cover the beds sooner than when turned out of small pots.—W. Osborne, *Fota, Cork.*

REMOVING LARGE TREES.

As inquiries are occasionally made on this subject, my experience may, perhaps, be useful. I have removed trees of from 4 to 6 tons weight which have re-established themselves quickly and given the utmost satisfaction. I am not sure that I can make my mode clear, simple as it is, as I am more at home with the actual work than in describing the plan for others. I am, however, willing to make the attempt, and perhaps those who may be particularly interested will by a little study become conversant with what I endeavour to explain.

We will take the case of a Wellingtonia 15 to 18 feet high. The first thing is to tie all the lower branches carefully upwards to the trunk, so as to clear the base and afford clear room to work. When this is done decide which way the tree is to be drawn, and that side we will call the front. Now at 4 feet from the stem mark-out a trench at the least 5 feet wide or long, and dig-out the soil to the depth of 5 feet. This trench next the tree must be cut straight and square down, the opposite side of course being sloped to facilitate the drawing of the tree from the hole to the level ground. When this is done dig-out a similar trench on the opposite or back side of the tree. Now, suppose these two trenches are cut and we commence to undermine. But first have six or eight sound and strong 9-inch deal planks ready, and as many blocks as there are ends of planks. Commence to make a hole through the lump of earth at 3 feet from the surface. The top of this hole, which will be the bottom of the ball, must be perfectly level. The hole may be 2 feet wide or more as is convenient, but the nature of the soil must be the guide. When ready put through one of the planks and tighten it up with a bottle-jack in order to put a block under—that is, one under each end of the plank, having the front block somewhat the longest. Proceed the same with the other planks, blocking each securely as it is put in. When all are screwed-up level, and safely blocked, see to the rollers.

There must be three of these of at the least 6 inches in diameter, and 2 feet longer than the platform on which the tree rests is wide. These rollers must have two holes near each end in which to put crowbars as levers to move them by. Lay two planks under the platform for the rollers to work on. Now take four other strong planks, placing two under the ball of earth and two on the top exactly over them, and bolt these together by iron rods with screw and nut at the end of each. Four of these are required, one at each corner, which will grasp the ball from above and below, and keep all firm and tight. Care must be taken that the tree is in the centre of the platform. Now place the rollers under the platform, one as near to the front as possible, and the other two-thirds under. After making certain that the platform is level and secure, proceed to cut the sides, and the whole weight is on the rollers. The mass must now be drawn from its place.

This can be done by men and ropes. I use stout waggon ropes. Fasten these round the ball, then try the length of the ropes, and at or near their extremity drive into the ground two stout stakes. These must be square with the frame of the tree and must be put in with a sharp slant from it. These stakes must be very firm (as everything depends on them), so that they are not drawn back and upright by the weight of the tree. To secure this strength other stakes are sometimes necessary with a coupling chain, which an intelligent labourer will know how to fix. Now have another roller quite 4 feet long and 8 inches in diameter with a hole through each end. Place this roller on boards behind the slanted stakes and fasten the ropes to it. The tree is now ready to be moved. Two men must be at the stake rollers, and a sufficient number at the tree. As soon as the word of command is given the crowbars are put to work both at the tree and stake rollers, when the bulk moves and the ropes wind round the roller at the stakes. It is now a question of moving and blocking the rollers and steadying the tree, and with plenty of strength (men should never be limited at this work), the tree will soon be on the level ground. The stake roller and long ropes are now done with, and the tree is moved by the platform-rollers to its new site if that is near. If, however, it must be taken some distance, horse labour and wheels are requisite.

In this case my plan is as follows; but to simplify the matter I assume that most people who are at all acquainted with trees have seen a felled tree removed from the wood to the carpenter's yard by a "pair of wheels," as they are called in some counties, or the "wood gin" in others. The wheels are simply run astride of the tree which is fastened to the axle by a chain underneath. The shafts during the operation of fixing are elevated, which lowers the axle. The shafts are now used as a lever, and by drawing them down the tree is raised from the ground and is drawn easily away. That being understood I lay two trees side by side, yet not quite closely. They should be straight and strong enough for the purpose. On these trees I place the tree requiring to be moved, lifting the mass by the aid of a screw-jack until I can roll one of the trees underneath. Then treat the other side the same, and the platform rests safely on the two prostrate trees. These should be wedged to prevent them rolling. Now two pairs of wheels or gins are placed astride the trees, running them back to back until they reach the tree and bulk of soil which is placed on them. By fastening as above described and drawing down the shafts the weight is safely suspended. Nothing remains now but to yoke the horses and draw the wheels—one pair of course running backwards—and the home-made tree-moving machine is complete.

To remove the mass from the wheels, ropes and rollers are again used. When the tree is in the hole, its correct depth having been previously ascertained, unscrew the holdfasts at the corners and take away the cross planks. Block the other planks at the ends except the middle one, draw this away, and then the next and next, finishing at the sides, and the work is complete so far as regards the moving. With due attention to firming and watering, trees of great size can be moved by this simple means.

My practice is not given because it is the best, but as enabling anyone to make his own tree-lifting machine from materials which are found in nearly every village. Properly-constructed tree-lifters are often a hundred miles from the place where they are required, and by making known this efficient substitute it can hardly fail to meet the requirements of some of the readers of the Journal, and, perhaps, of "T. S.," who on page 148 of the present volume seeks advice on this question.—A. M., *Essex.*

GLOXINIAS AT M. LOUIS VAN HOUTTE'S.

Mr. Luckhurst in his seasonable remarks on raising these beautiful plants from seed reminds me of a display I have seen in the famed Belgian establishment of M. Van Houtte. This collection certainly merits notice, as being probably the most extensive in the world and of unsurpassable merit. The mode of culture adopted is exceedingly simple and altogether different to that commonly seen and described in England. It may not be adapted to our wants and ways, yet in a more limited manner it may possibly be successfully carried out by those desirous of raising the finest corms in the quickest manner and with the smallest amount of cost in attention.

The collection in bloom at the time of my visit consisted of 50,000 plants, each plant carrying twenty to fifty flowers, and set in foliage of the most perfect health imaginable. The period was in September, and every plant was raised from seed sown in the spring, and not one plant was potted, or ever had been, during the period of its existence. Besides this collection there were numbers of plants grown in pots for the decoration of the different glass structures, and these were fine, yet they did not equal in freedom of growth and size of blooms the immense stocks planted out to raise roots for ex-

portation, and as a nursery ground from which to select new varieties to add to the catalogue collection.

The appearance of this immense plantation of Gloxinias was a sight which can never be forgotten, not only as to its novelty, but of the indescribable beauty and richness of the million of blooms. There would be at the least that number, and their effect in all the varied colours which the species down to that time had been capable of producing may be in some measure imagined, but cannot be clearly described.

Now this extraordinary collection of seedlings was not planted out in heated houses or pits, but only in unheated enclosures, which some might call an apology for cold frames, so exceedingly simple was the arrangement of the shelters, for structures they can hardly be called. They consisted of 2 to 3-inch deal planks set on edge, enclosing a width of about 7 feet of space, and on these planks the lights rested after the manner of improvised frames for the use of hardening-off bedding plants. The back ranges of planks might be about 15 inches in height, and the front rows something less than a foot—in fact, just sufficient to provide an ample slope to carry off the water from the glass.

Had these rows of frames been placed in one length they could not have reached far short of a mile. Now, fancy a border of Gloxinias a mile long and 2 yards wide. Better, however, not exaggerate, but see what that represents; well, at a foot apart it would contain 31,680 plants; but the number in bloom I was positively assured—and I inquired of three different men—was upwards of 50,000. The glass, however, was not in a row, but was arranged in a sheltered square of the nursery, and appeared to cover an acre. Well, then, an acre of Gloxinias, what does that represent? At a foot apart it will be 43,560, which does not reach the number within 6400; but as they were planted about 9 inches apart, and there were paths between the frames, the Gloxinia garden may be fairly set down as an acre in extent.

But to see the plants in such perfect health it was almost incredible that no artificial heat was used. That there was neither hot-water piping inside nor manure linings outside is certain, and I was further assured there was neither one nor the other used beneath the soil to afford bottom heat. The only heat used to grow the Gloxinias so splendidly was from the sun alone. The soil in which the plants were growing was mainly leaf mould, of the same nature as that in which Camellias and Azaleas luxuriate in so remarkable a manner. The seed of the Gloxinias is sowed in February, and when large enough the seedlings are pricked out in pans. As they grow they are allowed more room, and when the weather is favourable, about the beginning of June, they are planted in their blooming quarters. The principle of culture is to keep them growing and to suffer them to receive no check, or want of food or room, from the first period of their vegetation. They certainly were blooming magnificently, and many of the flowers were of great size.

Out of this immense number of plants less than a dozen were selected to add to the catalogue collection and for propagating purposes. The rest are all sold. They are classed in categories of quality, and sent in a dry state by the hundred and thousand to all parts of the world, and the purchasers name them or not as they choose. The corms are by this mode of culture brought to perfection the first season, and will produce plants of any size required. They are produced better and at a smaller cost in labour than if grown in pots, and are consequently sold at lower prices than would otherwise be remunerative. Now in raising Gloxinias in quantity and for testing seedlings, surely some modification of that mode is adaptable to many parts of England. I am not conversant with the mean temperature of Ghent, but as being the same latitude as the south of England the plan, with the same care that is given in Belgium, should hardly be considered impossible here. If, indeed, a little material for bottom heat were required, it would be as well applied as in growing bad Melons. Useless frames could be utilised, and a beautiful flower supplied at a cheaper rate and remunerative to the producer than is the case at present, and its cultivation would spread into every garden in the land that afforded convenience for its culture. The Gloxinia would, furthermore, be in more general use for summer and autumn decorative purposes in towns and cities from where it is in a great measure excluded by the costliness of the present mode of production by artificial heat and potting.

At any rate, if it is not practicable to thus cultivate them in England, it may not be devoid of interest to hear how they are so freely, easily, cheaply, and perfectly produced in other lands, and hence these remarks of—An Ex Visitor.

LOOK OUT FOR QUEEN WASPS.

Now that the time is at hand when every wasp that may be seen will be in search of a location for a nest, and if unmolested will become the parent of thousands, I would ask all gardeners—yes, and bee-keepers too—to kill every wasp they possibly can; for by killing the early wasps we can expect to gain a victory over such pests during the fruit and honey season.

There are few insects more annoying to the gardener than wasps. They attack the best fruits in the garden, although the gardener tries all preventives he possibly can think of—such as bottles containing sweet syrup, gauze over the apertures for ventilation, gauze bags made to fit each bunch of Grapes, &c., which bags to my mind do not look well in any vinery, as they hide the beautiful fruit when the eyes should be feasting thereon.

Now I think if gardeners, or horticulturists in general, were to form unions in their several districts, and offer a reward to all those who might choose to kill wasps from as soon as seen until the end of May, they would destroy hundreds of queens and prevent thousands of wasps that otherwise would come forth.—William Laurie.

OUR BORDER FLOWERS—PENTSTEMONS.

In this as in some other tribes of plants a little confusion exists in regard to their names. Pentstemon pubescens has been called Scouleri, and P. Richardsoni confounded with P. venustum; when such is the case it is an unfortunate circumstance. I know that it is a very difficult matter to keep plants true to name, as sometimes in changing hands mistakes are made, and perhaps not at once discovered. To enumerate the family is not my object, yet I would direct attention to a few neglected varieties that ought to be more frequently seen in collections of border flowers and for rockeries.

Pentstemon ovatus is one of the most desirable plants we possess; it has beautiful blue flowers, and grows about 1½ foot high. It seeds freely, but is kept true by division. It is desirous also for pot culture. The white variety of the above is a perfect gem in its way. These, I am inclined to think, are the best of the race. P. Scouleri is a plant seldom seen; it is of rather prostrate habit when left to itself, but with care may be made a very effective plant for all purposes. It strikes readily from half-ripened shoots, and grows well in sandy loam and peat, but must have thorough drainage. When in bloom its lavender-coloured flowers are very attractive. It is indispensable as a rock plant, and will repay any amount of care bestowed upon it.

P. Richardsoni is a very useful border flower continuing in bloom most of the summer; it requires attention in tying-up, and is best raised from cuttings. It is quite hardy. P. venustum is of graceful habit, and is one of the earliest bloomers of the family; it is of light purple colour, and is very desirable. It should be raised from cuttings. Pentstemon glabrum is of dwarf habit, is of purplish blue colour, and ought to be more cultivated than it is. P. pulchella is a very graceful plant of good habit, the colour being rosy lilac. It is best increased from cuttings yet seeds freely, and from a small packet of seed many different coloured flowers are obtained. There are many more of this interesting family which require to be better appreciated.

CHELONE.

This is a small family of plants allied to the Pentstemon; I like, however, to have them to themselves. They will succeed well under the same treatment as the Pentstemon, and are best increased by division in spring or autumn, but may be raised from seed if desired. They are of slender habit, but being generally tall-growing plants they require care in staking. They continue a long time in bloom; they are desirable as cut flowers.

Chelone barbata is the most frequently met with, and is said to have been introduced from Mexico. C. glabra is a very desirable American species. C. obliqua should find a place in all borders where herbaceous plants are cared for; its colour, which approaches to purple, contrasts favourably with the scarlet and white varieties. C. Lyoni is a very useful plant in open spaces in the shrubbery. The soil should be well broken up, and have an admixture of loam, peat, leaf mould, and sand, and the site should be well drained. When thus

cared for they will well repay any extra labour bestowed upon them by their beauty through the summer.—VERITAS.

FORCING RHUBARB.

I AM no stranger to the putting of long dung on the top of Rhubarb roots in November, having covered up some scores of acres in my time, and have a vivid recollection of pulling it in the locality of Woolwich on cold frosty mornings. But this kind of forcing is beside the question; yet I may add that this very season I covered up a large bed here, which is now 5 inches long, March 16th. Mr. Saunders may say I have not the early variety, but mine is Champion, from the best Rhubarb-grower in London, Mr. W. Myatt. The question is simply, Is Rhubarb best grown in cellars or forced under tubs with leaves? My experience tells me that the latter is a long way the best; in fact, the two compared together is best described by using a Covent Garden Market term:—cellar Rhubarb is "thirds," or what is put in the middle of the "firsts" when being tied up for market. I may add, in conclusion, that Asparagus, Seakale, Rhubarb are all best forced without being lifted, and that at all seasons.—R. GILBERT, *Burghley*.

NOTES RELATIVE TO THE POTATO.

IN your Journal, No. 726, page 157, I read with interest "Notes Relative to the Potato" from Mr. Luckhurst, and, as he suggests, willingly contribute my practice, and also that of my employer, whose experience has extended over forty years.

He says, previous to 1847, the year of the great failure, as they call it, in this country (Ireland), that degeneration was very rapid; it was scarcely possible to have Potatoes for a very few years. Sets taken from the same lot of Potatoes and grown in the same ground were most decided in their degeneration, and only about half of them would grow satisfactorily.

Now in this district (Ulster) this degeneration has entirely disappeared, and Potatoes having proper care never fail to grow. Our reasons for this are, the blight comes on before the tubers are quite matured, and make better and surer-growing sets, as has been proven by myself, by lifting the tubers long before ripe. Mr. Luckhurst says he does not believe in blight-proof Potatoes. I think most people must agree with him; the nearest we can come to prevent it is suitable soil, dry situation, which the Potato is very fond of, and lift the crop as soon as possible.

I admit the tubers are often affected after being stored, but not so much so as when left in the ground exposed to autumn showers and fogs, the latter being very injurious to them. The soils best suited to their culture here are light loams and sandy soils mixed with peat. The manures are farmyard and common seaweed in equal quantities; but better still is Wrack (Zostera marina). I believe the Potato is very fond of potash, and the latter is possessed of a large proportion of it.

I hope to hear soon from more able pens the experience of long practice, which would be highly acceptable to amateurs on this most important matter.—JAMES KENNEDY, *Gardener, Comber, Co. Down*.

SOIL-MIXING FOR POTTING PURPOSES.

THE remarks on mixing soil by "A PRACTICAL GARDENER" are good and to the point, and are made at a very opportune time. One can hardly say too much in favour of the plan recommended. I daresay that many gardeners have often felt the need of such a preparation as that described on page 155, when a little of this and a little of that has to be collected, perhaps some being soddened with wet or frozen to such an extent so as to be really unsuitable for immediate use. How often I have felt the necessity of such a store is hard to say, but more times than I care to mention.

I will mention another good plan—that is, whenever any alterations are going on, such as relaying turf, save every shovelful and pack it away. I would also take the parings of walks wherever the soil is of a loamy nature and would pack it up in square heaps, as follows: First begin with a layer of turf, then have some well-rotted manure and make alternate layers of turf and manure, of course having a less quantity of the latter, after the fashion of preparing sandwiches. On completing the heap there would be no need to protect the sides from the weather, but the top might be made weather-proof according to the taste of the builder. If such a heap is put together at the present time it would be in fine condition in a year hence, or in less time if needed.

Many of us know that in well-ordered gardens provision is made for all these necessaries—viz., a compost yard where such matters are carried on in a systematic order; but every gardener cannot boast of such a place, hence the difficulty arises where to make these stores. Now there is more importance attached to this than many people imagine, and I think a word or two on that point will not be out of place.

I have seen similar preparations carried on in some out-of-the-way place under large trees; but I say advisedly, Avoid such situations if possible, and for this reason—that the store in question would act as a magnet to the roots of surrounding trees, which would be sure to eat up the sandwiches. I have so suffered through not giving the subject any forethought.

When such a heap is in a fit state to use there is no need to take the soil from off the top of the heap, but merely begin at the end or side as the case may be. A sharp spade will chop it down in slices keeping a perpendicular face, when all will blend nicely together, and would form such rich food that the queen herself—the Rose—would not object to the fare.—G. R. ALLIS.

ROSE TREES AND FROST.

As "P." wishes the experience of others on this matter, I write mine. My experience and treatment of Roses that have suffered from intense cold is precisely the same as his. I do not, however, cut away old wood unless it is injured. I observed what he has stated—namely, that the old wood suffered, and not the new twigs, in the spring of 1861. I wrote to Mr. Henry Taylor, of Fencote, Bedale, Yorkshire, an experienced rosarian, for an explanation of this, and nearly as I can recollect he replied, "Sap is a non-conductor of both cold and heat. It is certainly a non-conductor of heat: hence the iron-smelters stir the liquid with green wood and branches, and not with dead wood." The Roses here have suffered but little this winter; but wherever there is injury it is in the old wood and not in the new twigs, which are only injured at their extreme points.—W. F. RADCLYFFE, *Okeford Fitzpaine, Dorset*.

I do not think that your correspondent "P." is correct in attributing the death of the older wood of his Rose trees to the effect of the frost alone. There are two ways of growing Roses. One, that which is described by "P."—viz., the encouragement of young wood from the base and the annual cutting away of the old at pruning time; the other, the preservation of the main shoots and the removing of all buds from the base as soon as they show themselves. These two methods cannot be combined in the same plant. If the first be followed and gross shoots are allowed to grow from the base, the older wood above the point from which those shoots proceed will gradually become unhealthy, the bark will lose its fresh colour, the buds will break the first year unwillingly and produce weak shoots; if left another season they probably will not break at all, and the wood will gradually become quite dead. This will take place whether the winters be severe or the reverse.

The cause of it is not the temperature to which the plants are exposed, but the diverting of the main stream of sap from the older into the younger and more vigorous growth. The old wood dies, not because the sap in it is frozen, but because it has not been able during the preceding autumn to store up a supply of vigour sufficient to enable it to withstand a winter temperature; and any unusually severe weather only hastens what has already become inevitable.

Now if "P." will select a dozen of his plants and carefully cut-off every shoot proceeding from the base as soon as it shows itself, the main stock may be kept in perfect health and sufficiently hardy to withstand severe frost for almost any number of years. I have plants which have been so treated for seven or eight years, and the old stumps produce clean and vigorous shoots and perfect flowers every season. This latter method must be followed if you wish for specimen plants. When you have got your head into shape, the only way to keep it so and to preserve its health and vigour, is to prevent gross shoots from pushing from the base. The moment one of these is allowed to grow (and they are always the most vigorous), that moment the health of all above is impaired, and decay commences.

There is nothing, then, extraordinary in the fact that these strong, green, robber shoots, which are usually twice as thick and twice as long as any other on the tree, should be able to withstand the cold better than the half-starved older wood.

Keep the sap flowing through the old wood by allowing only those buds which proceed from the extremities of it to grow, and it will stand any frost as well as the young.

Is well-ripened wood hardier than that which is immature? Certainly; but then it depends upon what you mean by "well-ripened." The shoot which "P." speaks of as having pushed from the base of his Maréchal Niel is no doubt to all intents and purposes "well-ripened." Though, doubtless, succulent for the first month of its career, if it has grown some 5 or 6 feet it can be succulent no longer. The pulp has ere this changed into woody fibre throughout a considerable portion of its length, and this being the case, it is as frost-proof as if twelve months old. Possibly the extremity for a foot or 18 inches may be still pulpy: in that case it is most likely frostbitten, but the rest of the shoot has a better chance of life than the remainder of the tree which this gross shoot has robbed of a considerable supply of winter food.

Some may ask, Which is the better of these two ways of growing Roses? It all depends what you want them for. If you require trim shapely plants for ornamental purposes or specimens, and do not mind the trouble, keep down your gross shoots. The quality of the flowers as to size will not be quite so good, but you will make up for it in quantity. If you grow a large number, you must of necessity allow them to grow pretty much as they will, and select the best shoots at pruning time. If you grow for exhibition, encourage your strong shoots from the base, and cut out your old wood every year. Properly managed, these produce the best and largest blooms, but you must content yourself with a less number.—R. W. Beachey.

NOTES FROM NICE.

The wild flowers are certainly in great "abundance," and though from the increase of buildings and consequent enclosure of land, they are not to be now met with so near to the city, yet the market is profusely and cheaply supplied with them, and also with cultivated floral beauties. The leading sorts are Anemones of various colours, Hyacinths, Narcissus, Stocks, Wallflowers, Primulas, Violets, Roses, Lilac, &c.

It has been ascertained at Nice that the leaves of the large scarlet Geraniums, which grow there so extensively in the open air all the year round, have very useful healing properties when applied in various forms to wounds and bruises. The leaves are placed over the parts affected, or made up into a plaister and laid on as may be needed.

Medical Dairy.—This title sounds rather oddly, but it is nevertheless a fact, that there has, amongst other novelties at Nice, been recently established a dairy under this name, and it is stated that it has introduced a new system of taking medicine homœopathically, so as still further to carry out the minimisation of infinitesimal doses. Goats are kept, and when any patient requires a particular medicine it is first administered to the animal, and some of the milk afterwards taken by the invalid. Some goats are kept for particular medicines, so that there is the belladonna goat, arnica, camphor, &c.

ROYAL HORTICULTURAL SOCIETY.

I was much surprised to hear from the Chairman at the adjourned meeting of this Society on the 9th inst. that the opinion of the larger exhibitors at the four minor shows had been taken, and a committee formed for the purpose of inquiring into this special matter. Now I think it is pretty well known in the horticultural world that the firm of which I am the sole surviving partner were the originators of the spring exhibitions at the Royal Horticultural Society, and further, I personally made out the first schedule issued by the then Council, and we have been very large and successful exhibitors at these shows, as their prize list will testify, and for the past two seasons we have not been out in the cold at the Chrysanthemum Shows, and I have the presumption to assume that if anyone had been consulted amongst the exhibitors that Wm. Cutbush & Son of Highgate would have been in the party.

I do not desire to add fuel to the already fierce fire at South Kensington, but having had a message conveyed to me from one of the leading members of the Council through my good friend and neighbour Mr. B. S. Williams only one day after the Council had decided to withdraw the four minor shows, already advertised in the schedule for 1875, that the Hyacinth Show would not be held, and to save any expense or inconvenience to me the information was thus kindly conveyed. Not being fully satisfied, I wrote to the office, and received a reply from the Assistant Secretary, dated 13th of February, that it had been decided not to hold the Shows in March, April, September, and November. Placing full confidence in this and subsequent advertisements, I at once arranged to put back our collection of Hyacinths and early Tulips for an exhibition here at Easter, and which will, if all is well, be carried out. Judge, then, of my astonishment, one week only before the original date announced for the Hyacinth Show, to hear that the Council had changed their minds, and would, with certain reductions, hold this and the other three Shows.

I ask, Does the Council consider this justice to an old exhibitor and staunch supporter of the Society? Had the Council condescended at the first to have called the exhibitors together and stated the position they were in, I am quite sure there would have been found but one opinion amongst the trade exhibitors—"Hold all your Shows, pay the prizes you offer to the amateurs, and we will for this season do our best and support you *con amore*."

It is very hard upon amateurs as well as ourselves in the case of the Hyacinth, for, relying upon the fact of a schedule being issued, purchases were made of expensive sorts on purpose to exhibit, as they are of little use after. In general, for decorative purposes, a ninepenny or shilling bulb produces as good an effect, and I know many of our own clients are exceedingly indignant at the vacillating policy of the Council. If this is to be the course the Council mean to adopt—play at battledore and shuttlecock with the exhibitors—there can be no unanimity betwixt horticulturists and themselves.—James Cutbush, *Highgate Nurseries.*

ECONOMISING FLOWER POTS.

How to enclose a little bit of mother earth in which to grow a plant, and at the same time keep it in a portable state, seems at first sight a very simple problem indeed, and one which may be solved in a multitude of ways. Where only a few plants are concerned little difficulty is experienced, but when the few become thousands the accumulated little difficulties go to make up one so great that with many a flower-pot famine is an event which happens almost annually about this season, and it may therefore be worth while to take stock of some of the ways and means of meeting it. In the case of bedding Geraniums—and it is to them only that my remarks will apply in the meantime—many methods have been tried with the view of economising pots and space. But the best of them seem to me to be failures so far as true economy is concerned, pots being in the end by far the cheapest, entailing the least labour, and giving the most satisfaction.

One of the best substitutes are long narrow boxes about 7 inches wide by 6 inches deep, made of three-quarter-inch boards. This width will hold two rows of Geraniums, each row being placed about an inch from the side, and it is best to plant them not triangularly, but in pairs. The great disadvantage attending this boxing system is, or rather was, that at planting time it was almost impossible to remove them with anything like good balls, but this is now obviated in some measure by a variety of ways. One is to have a quantity of good sound turf about 2 inches thick, and free from perennial weeds, laid up in autumn and allowed partially to rot, though not to such an extent as to destroy the fibre. In preparing the boxes place a layer of this in the bottom with what was once the grassy side downwards, keeping it as whole as possible. Over this place a little soil, and then put in the plants in the usual way, and in due time they will root into the turf.

At planting time pretty good balls can thus be obtained by making a cut along the middle of the box, and across between

each pair of plants. For greater convenience at this time the boxes should be made with the sides nailed on the outside of the bottoms and ends, and in one side at least as few nails be used as possible, which side can be removed to allow of the plants being more easily removed. It is also a good plan to cut off a number of the largest of the leaves a few days before they are to be planted.

Another way is to cut up good tough turf into cubes of about 3 inches, and scoop a hole in each with a knife to receive the plant and a little fine soil, placing them afterwards closely packed together either in beds or boxes. When it is found necessary to increase the stock of Geraniums by propagating in spring, this method of afterwards accommodating them is preferable to the other.

A plan more satisfactory in its results, although giving more labour in the first instance, is to treat them as follows:—Provide a quantity of green moss, not sphagnum, for that is too retentive of moisture for the purpose, but some of the Hypnum species which is found growing plentifully in the woods, on trees and stones, and which can be removed in thin fleeces. If the plants to be treated are shaken from store pots, the surest way is to take a 4-inch pot and line it with a flake of the moss, then pot the plant in it rather firmly, and when this is done cover the surface of the soil with another thin flake, and then turn out the now moss-enveloped ball by giving the pot a smart tap on the edge of the bench. It is afterwards bound together by winding a strong strand of bast three or four times round it. These being packed in beds or boxes with a little soil between them are not unhandy at planting time, and do not experience much of a check. Of course the moss is never removed. With plants that have been potted off in the autumn, two in a pot, the same end is more easily attained, as the balls only require to be halved and each wrapped up in moss, care being taken that they are not too dry at the time.

Some very curious vessels are sometimes met with in cottagers' gardens and windows doing duty as flower pots, yet feats of plant-growing are often performed in these, which for grandeur of results as compared with the grotesque unsuitability of the appliances, may be compared with the feat of the tuneful French fiddler who could extract exquisite music from a wooden shoe.

One of the best Petunias I saw last year was a balloon-trained plant grown by an amateur in an Australian meat tin, and a worthy farmer with floricultural tastes whom I know, grows fairly good Zonal Pelargoniums in old sheep-dip jars.

Not long since I saw in Glasgow a hoary Saxifraga sarmentosa luxuriating in an ancient brass kettle suspended in a shoemaker's window. Doubtless this kettle had in its day done duty in many a stiff toddy brew, but its steaming days were done, and here in its old age it was calmly, usefully, beautiful. —Robert D. Taylor.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Gustavia gracillima. *Nat. ord.*, Myrtaceæ. *Linn.*, Monadelphia Polyandria.—Flowers light rose-coloured. "It is a native of New Grenada, where it was discovered by Purdie in the woods of Carmin, in 1845, forming a singular small tree flowering on its slender lofty trunk in July. In Mr. Bull's establishment at Chelsea it flowered in September of last year." —(*Bot. Mag.*, *t.* 6151.)

Masdevallia chimæra. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Flowers yellow, densely spotted with crimson. "It is a native of deep valleys in New Grenada, where it was discovered by Roezl, and imported by M. Linden in 1872. Mr. Bull flowered it in December last."—(*Ibid.*, *t.* 6152.)

Colchicum luteum. *Nat. ord.*, Melanthaceæ. *Linn*, Hexandria Trigynia. Flowers pale yellow. "It is a native of the mountains in the extreme West of India beyond the Indus, in Hazara, at an elevation of 7000 feet, where it flowers in December and January. An apparently identical plant has been gathered by Dr. Thomson, F.R.S., in the valley of Kashmir, at an elevation of 5-7000 feet, flowering in June; by Stocks in Beluchistan; and by Griffith, who is the discoverer of the species, in Kafferisthan, near Otipore, about the year 1840, flowering in April at an elevation of 6-7000 feet. It has also been gathered by Stocks in upper Beluchistan, and by Henderson in the Zoji pass in Kashmir."—(*Ibid.*, *t.* 6153.) It is hardy, and flowered at Kew in January.

Theropogon pallidus. *Nat. ord.*, Liliaceæ. *Linn*, Hexandria Monogynia.—Flowers very pale pink. "A very common Himalayan plant, from Kumaon, alt. 6000 feet, to Nepal and Sikkim, in which latter country it ascends to 10,000 feet; also common in the Khasia mountains, where it is found at 5-6000 feet towards the tops of the hills. It prefers mossy rocks and the bases of old trees, when the roots run rather superficially in the loose soil."—(*Ibid.*, *t.* 6154.)

Wahlenbergia tuberosa. *Nat. ord.*, Campanulaceæ. *Linn.*, Pentandria Monogynia.—Flowers white with pink streaks. "The tuberous rootstock resembles a cluster of small Potatoes placed on the top of the pot; the contrast of these grotesque objects, with the exquisitely graceful thread-like stems and profusion of pearl-white rose-streaked blossoms is exceedingly striking, and recommends the plant as a most desirable one for greenhouse and probably out-of-door culture. Of course care must be taken not to overwater the plant when past flower, or the tubers will soon rot.

"Messrs. Veitch had it in full flower in September of last year. They received it from Juan Fernandez, where it was discovered by their collector Mr. Downton in 1873."—(*Ibid.*, *t.* 6155.)

Cydonia Maulei.—A hardy deciduous shrub. "It is a native of Japan, and was first publicly made known by Messrs. Maule on the occasion of the visit of the Royal Horticultural Society to Bath in June, 1873, when a drawing of the plant, with samples of the conserve made from its fruit, was shown under the name of a Japanese species of Cratægus or Pyrus, and received a first-class certificate. The yellow fruit is roundish, slightly depressed both at the eye and stalk, and bluntly but indistinctly ribbed, while the five-celled interior contains numerous seeds or pips.

"The affinity of this charming plant is obviously with Cydonia japonica, the Japan Quince, one of the most ornamental of flowering shrubs, but it differs from that well-known species in the form of its leaves, and in the structure of its flowers and fruits. Mr. Maule informs us that it will not take when grafted on the Pear, but will do so on the Apple, and also on the Thorn.

"As a hardy ornamental deciduous flowering shrub this plant has few equals, its brightly-scarlet flowers being so abundant and so remarkably effective. They are freely produced early in May, and as we learn from Mr. Maule, the plants go on blooming without intermission till June, so that in the event of frosty weather there is always a succession of blossoms, some of which must escape injury."—(*Florist and Pomologist*, 3 s., viii., 49.)

Apple.—*Lady Henniker.*—"It is of the Codlin shape, the fruits being high, inclining to conical, and obtusely angular. The eye is small for such a large fruit, open, and placed in a deep angular cavity. The stalk is short and deeply placed. The skin is of a deep straw colour on the shaded side, light brown where exposed, and streaked with bright crimson, with a small patch of russet near the stalk. The flesh is of a pale yellow, firm and tender, of a brisk, sub-acid flavour. It is very excellent when cooked; and is in season from October to Christmas.

"It is a seedling raised by Mr. Perkins, the gardener to Lord Henniker, at Thornham Hall, Eye, Suffolk, and was awarded a first-class certificate by the Royal Horticultural Society."—(*Ibid.*, 61.)

HYACINTHS AT HOME.

Wm. Cutbush & Sons, Highgate.—We would that this charming spring flower had a place in every home small as well as great, humble as well as exalted. We note it now in one of the great homes, for is not the name of Cutbush and the Hyacinth inseparable? It is from the hilly retreat of this old-established nursery that some of the most splendid specimens have been exhibited.

It was here, we believe, that the idea of spring exhibitions first had birth, and which resulted in displays which have been and ought to be again amongst the gayest and the sweetest of the whole year's displays. If the public have not had spread before them the usual contributions of this nursery it is from no lack of will, much less from any deficiency of skill on the part of its head; yet, if Mr. Cutbush has been misled and his plants perforce kept, as it were, in ambush, he does the next best thing in his power—viz., if he cannot take his plants to the public he invites the public to visit his plants.

His home exhibition commences on Easter Monday, and we

can promise those who contemplate an escape from the din of the town—we can promise those dwellers in the country solitudes who employ a holiday in search of something good in the way of flowers, that a run up to Highgate will be well worth the time it occupies. They will find what we did not find—the plants attractively arranged. Ours was to view the work in progress, theirs is to see it perfected. We saw the spikes, and pronounce them fine; we saw the Liliee, and bespeak them excellent; the Camellias clean and glossy; the Azaleas—handy plants—profusely clothed with bloom; the Cytisus Atleeanus glowing, the Palms stately and elegant. These with other decorative plants are being put under tribute to make this home show attractive.

But as the Hyacinths hold the post of honour, the other plants being accessories—framework, as it were, for the setting of the picture—we will note some of the best, for growers generally to note again what best will give them a reward in return for sound and generous treatment. And first in respect of new introductions Mr. Cutbush has none to offer.

Of late years the importations of new varieties have had so much chaff mixed with the few grains of corn that the veteran grower has resolved to import no indifferent sorts, and has made a resolve to visit Holland in the blooming season and determine the merits of novelties before addiug them to his collections. He will neither add a new one nor reject an old one simply because it is such, merit and quality being his primary object.

Some of the finest of the dark blues are Argus, Baron Van Tuyll (fine), King of the Blues (extra), Lord Melville (very telling), Marie (immense spike). Of the light blues Czar Peter (excellent), Blondin (greyish, charming), Couronne de Celle, Grand Lilas, Orondates, Charles Dickens, and Pieneman (immense bells). The best of the nearly black varieties are General Havelock, Feruck Khan, La Nuit, and Mimosa. The most attractive amongst the reds are Garibaldi (very rich), Linnæus (bright), Lina (fine), Madame Hodgson, Mrs. Beecher Stowe, Prince Albert Victor (extra), Florence Nightingale (Fabiola), and Solfaterre. The best of the whites are La Grandesse (superb), Baron Van Tuyll, Alba superbissima, Grandeur à Merveille (flesh), Mont Blanc (very fine), and Queen of the Netherlands. The best yellows are Duc de Malakoff and Ida. Mr. Cutbush's nursery if not extensive is interesting; everything is in good order, the whole place evidently being under able supervision.

Messrs. Veitch & Sons, Chelsea.—Our next visit is to another great home of the popular spring flower, for as such the nursery of Messrs. Veitch & Sons has an undisputed claim. The firm did not enter the competitive lists at South Kensington, and thus we were unable to offer our customary meed of instruction to those who cannot for themselves see a great collection in bloom, and who turn, as a guide to selection, to the Journal's portraiture of the most striking flowers.

These flowers are the great feature at the present time, and, as seen in our advertising columns, an inspection of the plants is invited by Messrs. Veitch. We invite a free response, as a floral feast is spread which cannot but be enjoyed, and which will haunt the memory almost, or quite, until the Hyacinths come again next year. We will briefly note a few of the best, and will first glance at the new varieties.

In this small group Duchess of Edinburgh must head the list. It is a single variety, having a finely-built truss closely set with well-formed waxy bells, and is of an extremely delicate pink or flesh colour. Disraeli is a blue flower, with faint streaks of white at the edges of the petals; it has a beautifully-shaped truss, and is very promising. Baron Beust is somewhat similar to the preceding, but more white in the petals; it is a charming colour, with a rather thin spike. Princess of Wales is a semi-double pink-coloured variety, with a fine towering spike, and very attractive. Prince Tallyrand is a porcelain blue, with large bells of great substance and a medium-sized spike. Masterpiece is nearly black, with a plum-coloured bar down each petal; it has a fine-shapely spike, and is well to the front of its class. Negro is also a good black and maroon variety. Oriental Beauty is a pure buff in colour, having a dense spike and good. Queen of Naples is in the way of Von Schiller, but a shade deeper in colour; it is a promising variety, but the present plant is deficient in foliage.

Amongst the general collection of two hundred splendid examples of culture we notice the best of the reds to be Prince Albert Victor. It is a rich scarlet crimson, very telling and fine. Vurbaak is another exceedingly fine variety of the same type. Linnæus is a bright carmine, and an excellent sort. Of the lighter shades of red the best are Macaulay, carmine rose; Van Schiller, salmon pink; Koh-i-noor, semi-double pink; Fabiola, creamy pink, beautiful; and pink Charles Dickens.

Amongt blues King of the Blues is pre-eminent, followed by General Havelock, very dark; and the good old varieties Mimosa, purple; and Baron Van Tuyll, dark blue. Of the lighter shades the most attractive are Czar Peter, lavender mauve, very handsome; Lothair, pale blue, excellent; Blondin, a silvery blue, fine bells and spike; De Candolle, lilac with blue stripes; and the still good porcelain blue variety Grand Lilas.

The best of the whites are La Grandesse, a magnificent spike and fine bells; L'Innocence, very handsome; Snowball, wonderful substance, but short spike; Mont Blanc, massive and pure; Madame Van der Hoop, and the old favourite blush Grandeur à Merveille. Miss Nightingale is a fine double white, the bells being almost as large as Gardenias, and fine for wiring for bouquets and button-hole decoration.

Of the yellows the best are Bird of Paradise, bright and fine; and Ida, primrose.

Those are, in brief, the cream of the splendid collection now staged at the nursery, and in conjunction with the Tulips, Crocuses, Narcissus, Clematis, &c., the feast of beauty is rich, varied, and satisfying.

The varieties enumerated are the best of two grand collections, leaving out of the list, however, many others of nearly equal merit. They comprise old as well as new kinds, and are adapted to varying requirements and decorative purposes.

IRIS GERMANICA.

In mentioning the Iris we have in hand one of the most varied and most beautiful families of hardy plants. It is assuredly true that there is no class of plants in the temperate zone and very few examples from tropical climes that can unfold to the eye of the florist such an extreme range of colour, such varieties of tints, such delicacies of markings, such decided richness in body colour as the different types and sections which the Iris affords; in fact its very name is expressive, being derived from the eye, in allusion to the variety and beauty of the colours of its flowers.

The genus Iris has long been a great favourite in the flower borders of Europe, and until the last few years was plentifully found in almost every garden of note in Britain. It has, however, in common with many other border flowers lost caste as it were in the estimation of the new-fashioned florists who, trained under the "bedding" *régime*, where individual beauty was lost in the effect of gorgeous massing, and intrinsic excellence was set aside for symmetry of combination, were taught to regard our hardy plants as little better than cumberers of the ground: hence the Iris has fallen into something like general disuetude, but is yet far from lost. There has always been a few real flower lovers with strength of mind sufficient to enable them to battle successfully against the stream of fashion, and to fight a winning battle in preserving their favourites from being rushed into its devouring vortex. These have now the reward of finding their labours appreciated in the returning taste for the flowers which our forefathers loved to enjoy.

It must be so. The very nature of our constitution as a nation is to cherish all that pertaineth to us by the care of our predecessors, and to hand it down to posterity the better for our having it. That is a national trait, and however tastes may vary and new ideas find patronage the quality of conservation has deep root, and will assert its power in spite of passing obstacles which now and again may intervene and gain a momentary triumph. Not that the new is a necessary evil, and that improvements are to be slighted as mere innovations; not that the taste in floral combinations which has added a charm to many an enjoyable home is to be spoken of slightingly; not that the prevailing system of garden decoration would be relegated to the limbo of oblivion by one barbarous swoop. No! not that. Let it flourish with all the charms it possesses, and improve and give pleasure to the fullest extent of its capabilities; let it do all that, but let the old plants live and improve too. Let them be loved and cherished, and improved, and increased; not only tolerated, but admired; not only permitted to exist, but assisted to perfect themselves as friends worthy of a home and protective care. That is what we desire to see, and desire it because of the solid lasting satisfying pleasure this care would create. Our homes may be beautiful as ever by judicious combinations of systematic form

and coloration, but would have the additional feature of interest in the cultivation of beautiful flowers for the sake of their own individual and intrinsic attractions. It would, too, spread flowers where they are not now to be seen, and make many a dark spot of earth bright and pleasant and sweet. That is why we seek to popularise our hardy flowers as well as to preserve the use of and improve the taste in the disposition of everything that makes our gardens an integral and indivisable part of our homes.

The great family of Iris, of which we figure the most familiar type, is in its various forms calculated to add to any garden an interest and a charm it did not possess before.

Fig. 56.—Iris germanica.

They unfold their glowing colours at a period when such colours are scarce, and in the spring and early summer months present a richness that the gayest occupants of the conservatory and stove cannot possibly surpass. Thanks to the care of the admiring florist and to the enterprise of floral caterers, the Irises so far from being lost are offered in a variety not even approached when the flower was in the first stages of its popularity. The German Iris, which was then limited to blue, purple, and white, can now be had in collections of fifty or more named varieties, including almost every colour and tint that can be imagined.

This section are hardy herbaceous perennials, evergreen, and of the easiest possible culture. They are not at all particular as to soil, and will flourish well in any fairly good ground. They have further this great advantage, that they will flourish, at the least as well as any other flower, in the neighbourhood of large towns where most plants under the smoke-defiled atmosphere linger and die. They are increased by root-division, and the present is a good time to establish collections. They also divide well after the blooming period in May. They are admirably adapted for planting by the side of carriage drives and for shrubbery ornamentation, where they increase and flower year by year with very little care and attention. To furnish cut blooms for filling large vases they have at their season few if any equals as hardy flowers. The blooms if cut when one-third open will travel well, expand, and continue fresh in water for several days. Most of them have a delicate perfume, and are deserving a place in all gardens of town and country. They have further the property which at times is so useful of growing and blooming well under the shade of trees. This section grows to an height of 2 to 3 feet. It is unquestionably a fine old garden plant, and there we leave it.

We would now notice a few others perhaps still more beautiful than the above, and adapted to different modes of culture and decorative purposes. Their dimiuutive growth renders some of these particularly suitable for pot culture, for which purpose they are highly commendable. What have we—what can we have more richly beautiful and at the same time sweetly perfumed than the early-blooming I. Reticulata? This variety has every claim to become popular as a spring-blooming conservatory plant, where it may be had in bloom in February. At that time nothing can compare with its deep blue flowers. Bulbs of this should always be ordered with the Hyacinths, and planted three or more in a pot, and they will give a reward commensurate with any care bestowed in cultivation. For pot culture a portion of old peat mixed in the soil is an advantage, but is not a necessity, as the variety will grow in any ordinary light soil. It will grow equally well in the open border, being perfectly hardy, and is one of the most attractive spring-flowering bulbs that can be grown. It blooms freely in March or April, and used in quantity no dwarf plant at its season has a richer effect. Its height is less than 6 inches. This variety is not yet common, but its intrinsic merits when better known will demand its increase. It is not of recent introduction, having been sparsely cultivated in English gardens for fifty years. Allied to this is the still older I. Persica. This is an exceedingly rich-coloured sweet-scented variety, adaptable for in or outdoor decoration, and being more plentiful and cheap than the foregoing should be largely grown.

Then follows the dwarf-growing group of Crimean or Austrian Iris. These are now offered in almost every colour, and make charming permanent edgings in suitable places in the spring garden or shrubbery. They are perfectly hardy, and will flourish in ordinarily light drained garden soil.

The numerous varieties of Spanish Iris, which are of intermediate growth yet later in blooming than the foregoing, by their rich contrast of colour will add a tone of brightness to the garden wherever they are cultivated. These vary from pure white to rose, deepening to blue, purples, clarets, and crimson, and afford a choice for cutting from as to be almost indispensable for this purpose. They flower usually in June, and are fine in groups for the mixed border.

A very charming variety for pots is the Peacock Iris (Viensseuxia), its white ground and purple blotch being distinct and effective. I. Susiana is a distinct, hardy, and remarkable striped variety, growing to a height of 2 feet, while the curious I. tuberosa (Snake's-head Iris) is singularly distinct and interesting for pots. While we have not enumerated a tithe of the many varieties of this fine hardy genus, not having even mentioned the great Japanese type of I. Kæmpferi, sufficient has been said to indicate the extreme variety of form, colour, time of flowering, and decorative adaptability which the family possesses. For varied and attractive qualities, for hardy constitution and easy culture it is difficult to name any other class of plants which equally embrace these advantages. They are recommended to all who love flowers. There is no place in a garden in which one or other of the kinds will not flourish. By the sides of streams or in woodland walks the larger sorts are at home. For choice spots and favourite nooks the smaller sorts will flourish and give pleasure, and for mixed borders the Spanish varieties will give enjoyable variety. For the greenhouse and conservatory a portion of them are worthy, and for indoor decoration as cut flowers all are to be placed in the front ranks as particularly and pre-eminently suitable. When once the richly varied collections of Irises are brought under general and systematic cultivation a feeling of surprise will become engendered that these beautiful hardy plants have been so long neglected.—W.

STANHOPEA.

This is a singular and extremely beautiful genus of epiphytal Orchids. The pseudobulbs, as may be seen from the woodcut, are furnished at the top with a solitary leaf, which is leathery in texture and has prominent midribs. The flowers emit a powerful odour; a single spike of three or four flowers will scent a very large house.

There are more than three dozen species and varieties in cultivation, but none of them are much valued by Orchid fanciers. The flowers do not last more than a week in beauty,

nor are they of any value for the purpose that the largest proportion of flowers are grown at the present time—viz., for cutting either for bouquets or decorative purposes in the house. The scent is too powerful when the flowers are placed in close rooms; nevertheless their large size, singular formation, and brilliant colours make them generally interesting, and they are valued by all who really love flowers for their own sake and are not ruled by the fashion of the hour.

Fig. 57.—Stanhopea tigrina.

None of the species can be said to be shy in flowering; with ordinary stove culture they flower every year during the summer or autumn months. In a recently published botanical dictionary pot culture is recommended for them; but if this system is followed out the plant must be raised very high above the rim, or the flowers will make a struggle to open amongst the drainage at the bottom of the pot.

The best way to grow them is in baskets made of teak, and the spaces between the strips of wood should not be less than an inch. On one occasion we had the care of some excellent specimens, which were grown in shallow baskets, but the pieces of wood were too close together, and the spikes of flowers which grow out at the sides or bottom of the basket could not get through.

The best material to fill up the baskets with is tough fibrous peat, sphagnum, and potsherds in equal proportions, with a

few lumps of charcoal added. Before filling the baskets a layer of potsherds should be placed in the bottom, and over it some clean live sphagnum; the moss that is mixed with the compost should also be fresh. The base of the pseudobulbs should just be covered when the plant is put into the basket.

The Stanhopea is not very subject to the attacks of insect pests. Red spider, however, is occasionally troublesome in hot weather, but a free use of the syringe and tepid water will either prevent their attack or dislodge them after they have gained a footing. When the bulbs are matured water should gradually be withheld, and they should only have enough to prevent them from shrivelling.

S. TIGRINA is one of the finest of the species. The flowers are very striking and handsome; the ground colour is orange, irregularly spotted with reddish brown. It is a Mexican species, and was introduced in 1836. Dr. Lindley observed that the flowers of S. tigrina are larger and handsomer than those of any other known species, even exceeding those of the magnificent S. Devoniensis. It flowers in August. Mr. Bateman states that it was originally imported from the neighbourhood of Xalapa by Messrs. Lowe & Co., and that it is among the easiest of the genus to cultivate. The fragrance of the flowers is very peculiar, resembling a mixture of Melon and Vanilla.

LONG-STEMMED AURICULA.

A CORRESPONDENT in the Journal of March 11th writes about a long-stemmed Auricula, and "D., *Deal*," gives him no satisfaction.

Some varieties, such as Martin's Mrs. Sturrock and Campbell's Lord of Lorne, are very prone to make long bare stems. In my judgment your correspondent may safely shorten the stem, and replant as deep as the leaves.

If the stem is furnished with roots so far as it is under ground, let him look for a slight contraction of the stem, somewhat like the joint of a finger, and here he may cut. Let him dip the stem in powdered charcoal, and let the cut base rest on the same. I have always found it necessary to be careful about the proper place for cutting the stem or tap root. Those contractions I speak of seem the best place for a new point of departure. Of course your correspondent will take care to preserve a sufficiency of roots; and I would not recommend the operation to be performed except in May or end of July.—FREDERICK TYMONS, Clk., *Cloghran*.

DALKEITH.—No. 3.

ALTHOUGH there is no flower garden proper at this fine place, yet there are flowers in immense quantities in the first order as to culture, and extremely effective as to taste in arrangement. These are planted in borders contiguous to the glass ranges and bounding the walks of the kitchen garden. No great variety of plants are used, but rather large quantities of the few which flourish the best, and are the most distinct and suitable are cultivated.

It will not be necessary to detail the mode of planting, yet, as giving a general idea of extent and arrangement, we notice the 10-feet-wide borders on each side of a broad walk 460 feet long. These are scolloped back and front, and have a row of circles 6 feet in diameter down the centre. These circles were filled with Lobelia speciosa, having a centre plant of Centaurea; the scollops being filled with Cerastium, Gazanias, and Geraniums Manglesii, Amy Hogg, Trentham Rose, &c. Another walk, 350 feet long, has similar borders, but planted differently. Ageratum, Crimson and Purple King Verbenas, Dactylus glomerata, and the still fine old Geranium Trentham Rose being mainly used. These borders are broken by several detached beds.

We take, as an example, a large circle raised to a height of about 4 feet at the apex of the bed. It was planted as follows: The outer line (15 inches) with Sempervivum californicum, followed by a similar width of Arabis lucida variegata; next, a row of large plants of Sempervivum tabulæforme, backed by a circle of Polemonium variegatum. From this circle the bed is divided into six panels, filled with Iresine Lindeni and divided by Polemonium running up to the centre, which is finished by a fine plant of Yucca aloifolia variegata. That is a grand bed, the luxuriance of the Iresine and Polemonium being strikingly effective.

We yet come to another walk with its flanking borders even longer and finer in effect than the others. In these the brilliancy of Tropæolum Cooperi was the telling feature. Even now I have not half enumerated the brilliant borders of Dalkeith, but some idea is given of their extent and richness. We now take a rapid run through the kitchen-garden department, extending to eleven acres under crops, and containing a large collection of all the best sorts of hardy fruits. There had been a fine crop of Pears on both walls and standards, some of the best sorts being in 1874 fully as fine from the standards as from the wall trees, such as Beurré Diel, Beurré Rance, Marie Louise, Williams's Bon Chrêtien, Duchesse d'Angoulême, Beurré de Capiaumont, &c., of which the fruit room contained good specimens. Apples were only a light crop, but the fruit was good in size and quality, although the light soil is not naturally well adapted for Apples, Plums, or Cherries. Small fruit had also been a very good crop, and large quantities of all kinds are grown, principally for supplying fruit for preserving.

With a liberal supply of manure, fine crops of vegetables are raised, the leading sorts being grown in large breadths to meet the wants of the establishment. Very few sorts of a kind are grown, good crops of good quality being more an object than mere variety. Most new vegetables of merit, or supposed merit, have a fair trial, but very few of them stand the test against older and well-tried sorts. Prominent amongst the newer vegetables is Veitch's Autumn Giant Cauliflower and Osborn's Forcing French Bean, both of which do well here, and have taken the place of older sorts in use at the same time. We noticed a large breadth of the "Dalkeith" Brussels Sprouts, a compact-habited and very prolific variety, that has been grown here for many years, and which has been found to keep in a bearing state longer than any other sort grown.

We observed a commodious gardener's house had just been erected, and further and better conveniences for the young men are contemplated, the Duke being proverbial in providing for the dwelling and comfort of all his dependents. The town of Dalkeith is of pleasant aspect, and evidences more than a common display of window gardening. This is at all times a pleasing feature, and a sure sign of the cleanliness, thrift, and intelligence of the inhabitants. The taste for domestic floriculture is no doubt fostered by a judiciously-managed Horticultural and Industrial Society, and the numerous gardens, both large and small, in the neighbourhood.

This closes our notes of what is undoubtedly one of the best, and best managed, gardens of Britain—a garden which a holiday gardener would do well to visit: he will see sound thorough practice rather than mere show, and will receive a courteous welcome from one of the most able and worthy members of the craft—the intelligent superintendent—Mr. Dunn.—J. WRIGHT.

NOTES AND GLEANINGS.

THE POTATO being a product of national importance, a Committee has been formed to give the utmost encouragement to its cultivation and improvement, and to promote the production of new and improved varieties, and to bring these more prominently before the public an exhibition is proposed to be held in London. We have seen the schedule of prizes, which are liberal, and when advertised, so that growers may see that the promoters are trustworthy, we have no doubt they will heartily respond.

—— DR. KALENDER of Linderhöhe, near Cologne, gives an elaborate account, in the *Kölnische Zeitung*, of the new enemy to the Potato which has caused such ravages in the Potato plantations of the United States—namely, the Colorado Beetle (Doryphora decemlineata). The general opinion on this beetle is rather uncertain at present, some considering it almost harmless, while others attach great importance to its being prevented from visiting Europe. Dr. Kalender applied to the Prussian Minister for Agriculture, and obtained the most reliable information, which is based upon a report of Mr. C. Riley, in the "Annual Report on the Noxious, Beneficial, and other Insects in the State of Missouri." It appears that the insect passes the winter in the ground, but as soon as the Potato plants have developed their first shoots the beetle shows itself. The females then deposit their orange-coloured ova, in lumps of ten to twelve, upon the under surfaces of the leaves; the larvæ appear after five to eight days, and begin their destructive work, which lasts two or three weeks, after which period they transform into nymphæ; ten to fourteen days later the young beetles appear; thus one summer can see three or four generations, of which the last one passes the winter in the ground. The insect does not confine its devastations to the

Potato only, but has also been found to attack the young shoots and leaves of Cirsium lanceolatum, Amaranthus retroflexus, Lisymbrium officinale, Polygonum hydropiper, Solanum nigrum, Chenopodium hybridum and album, and even of Hyoscyamus niger. This variety of plants shows that the insect has great powers of adapting itself to its food, and to this it must be ascribed that it can only with the greatest difficulty be got rid of. The home of the insect was in the Rocky Mountains; with the westward progress of agriculture the cultivation of the Potato approached the birthplace of the insect, and it transferred its dwelling to the Potato fields, which of course were welcome food; thus in a short time it became a general plague. In 1859 it began its eastward progress, and has now reached the coast of the Atlantic; whether it will cross this ocean and begin its devastations in Ireland remains to be seen; much may, however, be done to prevent its appearance in Europe. The means used for its destruction are various; the most successful one has been the so-called Schweinfurt green (arseno-acetate of copper). This is mixed with flour and water, and the plants are sprinkled with the mixture. Although highly poisonous to animal life, the Schweinfurt green does not poison the soil, as it is perfectly insoluble in water, and the destruction of the noxious insect is almost complete. Dr. Kalender finally draws the attention of agriculturists to another Potato enemy, the Brystopha solanella, a minute moth which has made its appearance in Algeria; its larvæ completely destroy the Potatoes themselves, so that they become unfit even for pigs' food. The *Journal de la Société Centrale d'Horticulture en France* warns seriously against the importation of Algerian Potatoes.—(*Nature.*)

—— Among the late Prince Consort's many excellencies was a love and a superior taste for gardening. How highly appreciated is thus well told in one of his letters in the interesting "Life" just published. "As an art modelling is even more attractive than painting, because in it the thought is actually *incorporated;* it also derives a higher value and interest from the fact that in it we have to deal with the three dimensions, and not with surface merely, and are not called upon to resort to the illusion of perspective. As the artist combines material and thought without the intervention of any other medium, his creation would be perfect if life could also be breathed into his work; and I quite understand and feel with the sculptor in the fable, who implored the gods to let his work descend from its platform. We have an art, however, in which even this third element of creation—inward force and growth—is present, and which has, therefore, had extraordinary attractions for me of late years, indeed I may say from earliest childhood—namely, the art of gardening. In this the artist who lays out the work, and devises a garment for a piece of ground, has the delight of seeing his work live and grow hour by hour; and while it is growing he is able to polish, to cut and carve, to fill up here and there, to hope and to love."

—— Every member of the vegetable world in California is described as "vast" or "gigantic," and the following is another example published in the *San Francisco Alta.* "It has been supposed that the Sierra Sequoias, or big trees of California, are confined to a few small and isolated groves. It was discovered last summer that a body of big tree timber in Fresno county is not properly a grove, but a forest extending for not less than seventy miles in a north-west and south-eastward direction, with a width in some places of ten miles, and interrupted only by the deep canons which cut across the general course of the forest. Different persons have traced the forest from the basin of the Tule river in latitude 36° 20′ across those of the Kaweah and Kings to that of the San Joaquin. The elevation has not been carefully measured, but is supposed to vary from 4000 feet to 6000 feet. Unlike the groves further north, this forest consists mainly, and in some places almost exclusively, of the big trees, and there are also a multitude in all the ages of growth, some just sprouting and others saplings only 2 or 3 feet through. The largest standing tree as yet measured is 40 feet in diameter; a charred stump—the tree itself having disappeared—measures 41 feet across. A tree 24 feet in diameter 4 feet above the ground is precisely the same thickness 60 feet higher. A fallen trunk is hollow throughout its length, and the hole is large enough to drive a horse and buggy 72 feet in it as in a tunnel. The wood is similar in general character to the coast Sequoia, or common Redwood, straight in grain, splitting freely, even enough in grain for furniture, and far superior to Oak in its keeping qualities in positions exposed to alternations of drought and moisture. The Sierra Sequoia does not throw up sprouts from its stump as does the Redwood, and can therefore be felled out more readily. It was wise in Congress to make a reservation for pleasure purposes of the Mariposa Grove, which is near Yosemite, small and conveniently accessible to tourists by the present routes of travel; but the Tulare-Fresno forest—it is all in those two counties—cannot be converted into a public reservation. Numerous sawmills will be built on its line, and flumes will carry the lumber down to the consumers."

NOTES on VILLA and SUBURBAN GARDENING.

Kitchen Garden.—If previous advice has been acted upon—that is, if the soil of the garden has received its preparation by digging, trenching, manuring, &c., it will be found in an excellent condition to receive the seeds of various crops which ought to be now sown. The plan still adopted by many, notwithstanding that instructions are given to the contrary, of digging and manuring the ground at the time of cropping, is not giving the crops a fair chance. The aim of the owner of ever so small a garden should be to so work his soil as to have it in the best possible condition at cropping time, and this cannot be well done unless it is turned up in a rough state during the autumn, when it becomes pulverised and cleansed by the severity of the winter. A soil so treated will now be found to work down admirably, and it will not be bound down or thrown out of condition by being trampled upon during the process of cropping.

There is another matter I ought to mention, which is that some crops, such as Potatoes and Onions, do not turn out so well with manure applied at the time of cropping, especially if that manure is at all green or not much rotted down. The object should be to apply the manure at the earliest opportunity, and in such a state of decomposition that it can be appropriated by the crops at the time it is needed for their development. But there are some who will not move out of their usual track to benefit themselves, even though there is the prospect of increased produce from other and better plans which have been advised.

It is now time to make sowings of the general crops, to be grown whether the garden be large or small. If early Potatoes have been planted on warm borders watch for their coming up and protect them from frost, a little of which we are having every night. Plant Myatt's Prolific, American Early Rose, Brezee's Prolific, Early Shaws, York Regents, and Lapstone Kidney as soon as possible; the later sorts, such as Flukes, may be deferred later on if, as I presume, that all the space intended for Potatoes is not yet vacant, but if it is I would advise that all sorts be put in immediately.

As to the manner of planting Potatoes most of it is understood, but I do not advise anyone to adopt the plan of dibbling them in. It may save time, but it is the worst plan of any. The hole is made and the soil is compressed at the sides, which in a stiff soil is a greater disadvantage, because the roots are unable to obtain that freedom they need at starting into growth, and which is given them by adopting the plan of planting them either in drills or putting them in with the spade. And further, unless a very peculiar dibbler is used, the Potato does not go to the bottom of the hole, which is another disadvantage.

Of Peas there are many good sorts, both tall and dwarf growers. I should now sow a row of Veitch's Perfection and Williams's Emperor of the Marrows; the former grows 3 feet, and the latter 6 feet or more in good soils. If sown both at the same time they come in good succession, and are most excellent croppers and good in flavour.

Sow also the main crop of Onions on well-prepared ground, the White Spanish and James's Keeping are two good standard sorts. If it is necessary to manure the ground now use any old manure, but I prefer using the space occupied by Celery, as that being manured the year previously, and the ground being well worked, Onions generally do well. It being a deep-rooting plant a deeply cultivated soil is indispensable. Sow the seed in drills about an inch deep, and if the soil is light tread the seed in as it is covered. Those who grow the Giant Rocca and other autumn-sown sorts must now stir the soil between the rows and thin out where thick, and fill up vacancies by picking out some of the best.

Some early Horn Carrots to succeed those sown in frames or sheltered places may now be sown, leaving the main crop till the beginning of next month.

Plant a few rows of Broad Beans, either the Broad Windsor or Longpod; there is also the Dwarf Fan and Beck's Green Gem, both branching kinds and do not exceed 15 inches in height. These are excellent in quality and prolific.

If Spinach is required a few rows may now be sown, but this, being a crop which soon comes to perfection, should be sown between rows of Peas, yet on good rich soil. As its produce depends upon the size of the leaves, it requires thinning out to about 8 inches from plant to plant.

Make sowings in small beds or narrow borders of Brussels

Sprouts, Ulm Savoy, Couve Tronchuda, Cauliflowers, Enfield Market Cabbage, Paris White Cos Lettuce, Leeks, Radishes, and small salading. This may be followed up in another fortnight with small sowings of Snow's Winter Broccoli and other winter and spring sorts; also the autumn sorts, such as the White and Purple Cape, and Veitch's Autumn Giant Cauliflower, Drumhead Savoys, and several sorts of Kales, such as Scotch Cabbaging, Tall and Dwarf Green-curled, and the Buda Kale, which is a most productive variety.

Plant out Lettuces that have stood in frames during winter under a wall or on a border of rich ground. The same may be said of Cauliflowers that have been so preserved, and those under handlights must have the soil stirred among them and be encouraged to grow as fast as possible.—THOMAS RECORD.

DOINGS OF THE LAST AND PRESENT WEEKS.

HARDY FRUIT GARDEN.

NOTWITHSTANDING the continued cold weather the flower buds on Apricot and Pear trees are rapidly swelling, and a few mild days will cause the blossoms to burst open. On south walls Apricot blossoms which are already open require to be carefully sheltered from the biting blast by canvas screens, rolling these up in the middle of the day.

In our variable climate wall trees require much watchfulness at the time of flowering; keeping the protecting material down when it is not required weakens the trees and is injurious to the blossoms. The enthusiastic amateur or careful gardener will watch for the opportunity to roll-up the canvas and allow the sun to act upon the trees. After a frosty night, some time between the hours of 9 and 10 A.M. is early enough to uncover the trees in exceptionally bad weather, such as snow or hail; indeed, we have sometimes had it so cold in March that the rain drops have frozen on the trees. They ought to be effectually protected.

We have commenced to run the Dutch hoe through the borders of pyramid and bush trees. The surface had become caked by the rains, and seedling weeds are appearing above ground. If the hoe is kept well at work at this season weeds are effectually destroyed, and require but little trouble to keep them in check in the summer months.

Those who are much troubled with the maggot that eats into the centre of the fruits of Apples and Pears, would do well to throw some dry lime over the trees after wetting the branches with soapy water thrown from a syringe or garden engine.

Pruned Apple trees that were planted in the winter. The best time to prune newly-planted young trees is when the buds begin to move in the spring. If they are wall trees they ought to be nailed at the same time.

FRUIT AND FORCING HOUSES.

Vineries.—The inside borders of late houses have been watered now that the buds are starting into growth. The plan always adopted with early houses is to water the borders at the time of starting; but this is done to warm the soil a little, as if the border is moderately moist, as it ought to be, there is not much to be gained by watering it before the Vine is quickened into action. Vine roots are not like those of Pears and other fruit trees of the same character, which are forming rootlets in fine weather all through the winter months. The Vine does not seem to make any fresh roots until the leaves are formed, the first start being made from the elaborated and stored-up sap of the previous season.

There is no danger now of the Vines bleeding from late pruning. The system of cutting the fruit with the branch attached is not only a convenient one but also commends itself, because it prevents the fruit from exhausting the Vine, which it does by draining the sap from it. The splendid Alicante Grapes that gained the first prize at South Kensington last week had been cut from the Vine for a considerable time, and some of the other exhibits which were in good condition had been cut for more than three months.

The unfavourable weather, as was to be expected, has brought some signs of red spider into the early vineries.

In the early stages of the attack the best way to get rid of the spider is to wash the leaves with a sponge and soapy water. This requires much care, as the berries are easily damaged by rubbing the arm against them. Applying sulphur to the hot-water pipes will kill the pest if the pipes are hot enough; but all tender-skinned Grapes are liable to injury from the fumes, and great care is necessary when it is being applied. Slaking a 10-inch potful of lime in the house and throwing a handful or two of sulphur on the smoking mass has also been tried, but this operation is much more hazardous than the other.

Many gardeners who produce good Grapes syringe the Vines up to the time of colouring. If this is done thoroughly the spider will be destroyed, but the appearance of the Grapes is also spoiled. Tying the shoots and stopping the growths in succession houses and other routine work has been given in detail in previous numbers.

CUCUMBER AND MELON HOUSES.

Some growers of Cucumbers recommend at this season a minimum temperature of from 60° to 65°, but one of from 70° to 75° is much preferable, as if the fruit is not grown quickly it is sometimes bitter. In our houses there are sufficient hot-water pipes to maintain a minimum of 75° even in cold weather.

The same plants continue in bearing for a long period by periodically cutting-out the old exhausted wood and renewing with the young growths. During the winter season once in ten days is often enough to go over the plants; in summer they require attention every week. When the plants are not growing freely they have a tendency to produce a very large number of male blossoms, and as these still further tend to check the growths they must at once be pinched-off.

Preparing plants for planting-out in frames is not included in our "Doings," as the house is much more convenient. There is not much to be gained by planting in frames too early in the season; but if good sturdy plants could be put out now and the frames double-matted at night, the plants would start fairly into growth. The fermenting material of which the beds are composed should be well prepared. Stable manure and leaves in equal proportions make a lasting bed.

Melons are making good growth, but the plants are not grown enough to require stopping. This is done when they have grown-up to about half the length of the trellis. A watchful eye is kept for spider, which soon makes sad havoc with the plants. Syringing it off is the best treatment.

Figs.—These, being grown in pots, are moved from the house where they are started to the back stages in the Cucumber house. When the trees are dormant at midwinter it would not be judicious treatment to introduce them to a temperature of 65° or 75° all at once, but they are started with the Vines and are removed from the house before they receive injury from the shade of the Vine leaves. It has been said that Figs will do well under the shade of Vines; they may do so if the roof is not well covered, but when the Vine trellis overhead is covered as it ought to be, any Figs that may be produced underneath are not worth the trouble of growing.

Tomatoes have been potted-on into 9-inch pots, and it is always worth while to devote some space in the forcing houses to them. Excellent fruit is produced in May and June by sowing a pinch of seed with the Melons in January. The plants should be stopped when they have grown about a foot high, and no more stopping is required.

GREENHOUSE AND CONSERVATORY.

Insect pests seem to increase so much more rapidly during the prevalence of east wind that some persons have concluded that they come with it, and not a few have been driven to the theory of spontaneous generation; but all observant gardeners know well that anything which causes the growth to receive a check is the means of introducing aphis more rapidly to the plants. Fumigating with tobacco smoke is the most effectual preventive as well as remedy.

The Hyacinths are now in great beauty, and with the gorgeous early-flowering Tulips serve to make the houses very gay. To grow Hyacinths and Tulips well they ought to be placed in a house near the glass until the flowers are nearly open; this causes the spike to stand up boldly above the foliage. Neat supports made of wire and painted green are the best means of supporting the spikes. The wires should be bent at the end that is thrust in the mould to preserve the bulbs from injury.

Stage Pelargoniums must also be attended to now by being kept quite free from green fly, and the plants must also be quite close to the glass if the finest health and quality are desired. Specimen plants must be tied-out carefully. If the shoots are strong they readily snap-off at the base. It is best to bring them down a little at a time, and rather go over the plants more frequently.

Primula amœna and the white and lilac varieties should be grown more frequently for the greenhouse. The white variety is now in flower, and the others will soon be in. It is a plant requiring but little attention. At or before the flowering period the leaves are frequently attacked by red spider, and if this is not kept off until the crowns ripen a good bloom cannot be expected the following season. The shadings have been put up, as the sun had begun to act with considerable force on the glass.

FLOWER GARDEN.

Rolled the lawn with a heavy roller, and as soon as possible will run the lawn mower over it. The grass is always rough and uneven before it is mown for the first time.

Have put up a turf pit for the bedding plants, and shall lose no time in getting them into it, as the late vineries now require a little heat and the house to be shut-up early, which is quite the opposite treatment to that required for the bedding plants.

Potting of Coleus, Alternantheras, and other half-stove plants. Indeed, it is best if the more tender of the above are not placed in the cool house until May, and then only if the weather is fine. Moved bedding Calceolarias from a cold frame to the

earth pit. The plants will be planted in the trench when they have been inured to their new situation.—J. Douglas.

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Jersey.—May 5th, Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.
Bath.—May 12th, September 1st and 2nd. Mr. B. Pearson, 13, Milsom Street, Sec.
Coventry.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.
Durham and Northumberland.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.
Leeds.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.
Glasgow.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.
Fareham.—June 23rd. Mr. H Smith, Sec.
Exeter (Rose Show).—June 25th. Mr. J. N. Gray, Queen Street Chambers, Hon. Sec.
Wisbeach.—June 30th. Mr. C. Parker, Hon. Sec.
Spalding.—July 1st and 2nd. Mr. G. F. Barrell, Hon. Sec.
Tonbridge.—July 14th. Mr. W. Blair, Free Press Office, Hon. Sec.
Wimbledon.—July 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Sunnyside, Wimbledon, Hon. Sec.
Brecon.—July 22nd. Mr. W. J. Roberts. Sec.
Cleckheaton.—July 24th. Mr. S. H. Williamson, Hon. Sec.
Preston.—July 28th and 29th. Mr. W. Troughton, 4, Church Street, Hon. Sec.
Southampton.—July 31st and August 2nd. Mr. C. S. Fuidge, 32, York Street, Lower Avenue, Sec.
Ramsgate.—August 25th. C. D. Smith, Esq., 8, Marine Terrace, Margate, Hon. Sec.
Dundee.—August 26th, 27th, and 28th. Mr. R. McKelvie, 51, Reform Street, Sec.

TRADE CATALOGUES RECEIVED.

Charles Green (late Gardener to W. Wilson Saunders, Esq.), Botanical Nursery, Holmesdale Road, Reigate.—*List of Greenhouse, Herbaceous, and Alpine Plants.*

William Paul, F.R.H.S., Waltham Cross, London, N.—*List of Roses (New), Geraniums, Phloxes, &c.*

James Backhouse & Sons, York.—*Catalogue of Alpine Plants and Hardy Perennials.*

James Carter & Co, High Holborn, London. — *Illustrated Catalogue of Prize Farm Seeds and Potatoes.*

TO CORRESPONDENTS.

*** **All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.**

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

*** We have many valuable communications which we are obliged to omit until next week.

Books (*J. Kelly*).—Keane's "Indoor Gardening" may suit you. You can have it free by post if you enclose twenty postage stamps with your address.

Constructing Cucumber Pit (*M. A. H. B. L.*).—We should have the house sunk about 2 feet, and the walls about the same above ground. A span-roofed house would be best with a bed on both sides of the house and a walk up the middle. If you require one bed only, a half-span would be most suitable, having a walk along the back. The front wall we should have of the height named, and the back wall the height required to meet the back part of the roof. Not knowing the width we cannot give the height of the back wall. The roof only we should have glass, with one or both ends level with the front brickwork. Ventilating should be provided at the upper part of the roof. You will need two pipes for bottom heat to each bed, and four for top heat. The surface of the bed should be about 2 feet from the glass, and the trellis a foot from it. Your boiler will not heat more than 200 feet of 4-inch piping. We should have one a size larger, as it is better to have one above rather than under its work. Such a house we believe would not be portable, and it is well to be certain on that point before you erect.

Seakale after Cutting (*C., Killarney*).—The Seakale not having been forced, should have the blanching material removed when the weather is mild, yet before the growth is advanced. In cutting, the cut should be just at the base of whence the new growth proceeds. Just below this will proceed shoots which will give the crowns for next year's crop By keeping the crowns covered you will certainly secure a second crop of weakly stalks, but the growth afterwards made will be poor, and the produce resulting another year very indifferent.

Purple Broccoli (*Idem*).—These are not so desirable as the white, but are by many esteemed. The Purple Cape is ready for use in autumn. Dwarf Danish Purple and Sprouting come in during March and April, and Howden's Dwarf Purple in May and June. The seeds should be sown at the close of April or early in May.

Heating Houses (*J. P. of York*).—We do not approve of the 2-inch flow-and-return pipe from and to the boiler. We know the water will enter the boiler in a similar ratio as that passing out of it, but we maintain the water has not so free an egress and ingress to the boiler when 2-inch pipes are employed instead of 4-inch. The 2-inch pipes we should alter to 4-inch, and take them the entire length of the cold pit, across its end through into the stove, and through the stove in the way you show, but with the water flowing the reverse way to what is represented in your sketch. This will give you four rows of active piping, whereas by your plan half of the piping would be of no use only when you have heat in the vinery, and that will be in summer, when you want least in the stove. The advantage of the change will be equally great in the winter, as the vinery will then need to be cold. The flow pipe after entering the stove as far as you show may have a branch to the right and left, the right for stove, and left for cool vinery, upon which should be a valve, and the like arrangement of the return pipes of these houses will give you all you require. We should have the pipes in the vinery as shown in stove and greenhouse—*i. e.*, 4 inches from the edge of border instead of 3 inches, and they must be raised so as to be on the same level as those in the stove, or the circulation of the water will be sluggish, if not altogether arrested. Three-inch pipes will be ample for the vinery, but all the others ought to be 4-inch.

Adiantum farleyense not Thriving (*R. W. B.*).—It is a stove Fern, and to having been kept in a greenhouse we should attribute its present sickly appearance. Remove to a stove, affording a moist atmosphere, and shade from bright sun. Repot when it is growing freely. The bad appearance may, however, have been caused by fumigating with tobacco, of which it is more susceptible of injury by than any plant we know. If in a pot, as we presume it is, remove from the house whenever the house is fumigated. It does tolerably well in a warm greenhouse, being kept in the moistest part and shaded, but to have fine it requires a stove.

Orchard-house and Greenhouse Arrangements (*H. W.*).—The height of the back wall for a house the width you name, with a height in front 7 feet ought to be 15 feet, and you will need to provide efficient top and front ventilation. This is a very important point in greenhouse and orchard-house construction. You can have pipes put in on the opposite side of the boiler—*i. e.*, branching from the flow of the greenhouse for the orchard house, and taking it along that house, returning by the return pipe from the greenhouse. The pipes, as you have an open cistern, must all be on the same level. An air pipe on the highest part of the orchard-house piping will allow of air passing out of the pipes. The pipes in both houses when cold need not be more than three-quarters filled with water in the flow pipes, so as to allow for expansion, but taking care to have them so full as to insure the circulation of the water. Two pipes 4 inches in diameter along the front and across one or both ends of each house will be sufficient to exclude frost in severe weather, and by having valves on the orchard-house pipes you will be enabled to work them separately or together. We consider it a mistake to have Vines in the orchard house, especially on the roof, for though you may have good Grapes it will be had at the expense of the trees beneath. We should not have any on the roof, but you may have them as pot plants or planted out, but trained upright. You can have Vines in the greenhouse trained to wires 15 inches from the glass, and at 4 feet apart you will have room for five Vines. You will have space in your house for two rows of trees at 5 feet apart, which will be quite close enough. This will give you sixteen trees, and having the trees not nearer the back wall than 5 feet, and the pathway about 18 inches from it, and 2 feet 6 inches wide, enough light will be admitted to make the back wall available for Peach trees. We should have two—viz., Royal George and Grosse Mignonne, with an Elruge Nectarine in the centre. This plan will leave the front space available for other fruit trees.

Hedge for Hollow (*Vallambrosa*).—It appears you intend to make a ditch or trench, and you want to know what to plant in the ditch, and not upon the bank or side of the ditch. If the former we can only recommend Birch, which will grow well and does not make a bad fence, but is not good against cattle, though answering well as a screen. If upon the bank we advise Thorn or Quick, which is unquestionably the best of hedge plants. We think you mean in the trench, and therefore advise Birch, which kept well cut will meet your requirements. Birch, Alder, and Willow are the only trees suitable for such a position.

Wires for Pear Espaliers (*J. E.*).—Six wires 10 inches apart, the first a foot from the ground, will be proper for your trees; but we should have had the trees vertical trained and planted 5 feet apart, each tree with six branches, and the trellis 6 feet high, and the wires a foot apart. Horizontally-trained Pears on the Quince have the lower branches very often weak.

Fig on Greenhouse Wall (*Idem*).—With Vines on the roof at 3 feet apart you will have little chance of fruit from a Fig tree against the back wall. We have, however, known them do fairly, the Brown Turkey being most suitable. The wall, if you have the tree, which we do not advise, would be best wired.

Draining Fern Case (*Cryptogamia*).—At the bottom there should be a clear space of an inch; at this height have a second bottom of perforated zinc. A small pipe at one end coming outside the case from the open space will enable you to run off at will any surplus water, the end of the pipe being fitted with a thumb screw. Over the perforated zinc you will still need an inch of drainage; the best is charcoal broken up in pieces from the size of a hazel to a walnut, and passing it through an eighth-of-an-inch sieve to free it of the dust, and over this a thin layer of cocoa-nut fibre, or the rougher parts of the compost. The fine charcoal siftings will do to mix with the compost at the rate of one-sixth charcoal to the other parts of the soil. The Ferns have not hitherto grown because they are waterlogged.

Ribbon Border (*A. F. N.*).—The arrangement would look well. The best blue Ageratum is Chater's Imperial Dwarf. It comes readily from seed, but we prefer raising our stock from cuttings taken from plants selected for that purpose last season. Little Trot is by far the best and most compact white-edged Geranium, but as it is only just now being sent out you had better take May Queen or Miss Kingsbury for the present season. They are both excellent varieties.

Auriculas in House Facing North (*A. C. S.*).—The Auriculas might do in the situation proposed during the summer and autumn months, but I question their doing so during winter and spring. I never saw the varieties named, and so can say nothing of their merits.—D., *Deal.*

Hardy Rhododendrons (*C. T. S.*).—The following twelve are good:—Atrosanguineum, dark crimson; Titian, reddish pink; Queen, white; Stella,

pale rose; Purity, white, yellow-eyed; Briareus, rose; Chancellor, lilac; Formosum, white; Oberon, purple; The Gael, pink and yellow; Incomparable red; Lord Clyde, crimson; and Columbus, flesh-coloured.

Tracing Paper (*Anne P.*).—You may make and unmake the tracing paper you wish to employ for copying portraits of flowers, and then placing the copies in your album by thus preparing the paper. One measure of castor oil dissolved in two or three measures of spirits of wine renders paper transparent, and when the spirit has evaporated the paper soon becomes fit for drawing upon. If the paper is subsequently placed in spirits the oil is dissolved out, and the paper is restored to its original condition.

Passion Flowers (*C. J.*).—We do not know where the flowers can be now obtained.

Panicum (*A. K.*).—We do not know a species called Panicum capillaceum. There is P. capillare. It is a hardy annual, native of America. Its botanical characters are, panicles capillary, erect, spreading; peduncle straight; glumes acuminate, smooth; sheaths very hairy.

Seedling Briar Stocks (*M. P.*).—They are raised from seeds of the common hedge Briar. The plants are two years before they are large enough for budding. Leave the hips on the Briars until February, and then sow them. We think that stocks from cuttings are as good as those from seed. The lower buds of the cuttings should be rubbed off.

Seedling Primula (*A. A.*).—We do not discern any difference from a variety of the same colour to be obtained of florists.

Verbena Melindres (*E. Collins*).—Any of the florists who advertise in our columns could supply you.

Pine Apple Leaves Shrivelled (*R. S.*).—The leaf you sent is spotted from water having lodged upon it, and the sun falling powerfully upon the leaf whilst in this state has so heated the water as to destroy the tissues of the leaf. Such mishaps usually follow a period of dull weather, a few hours' powerful sun being sufficient to cause the mischief. The only remedy is more careful and earlier air-giving; better have them dry under bright sun, moisture being kept up by other means than syringing overhead.

Passifloras in Greenhouse (*H. T.*).—The Passifloras you name are very free growers and equally free flowering, and would cover a large extent of roof in a year or two. They may, however, be kept within reasonable bounds by frequent regulation of the growths. They would be best planted out in the border as you show at B. They are likely to suffer from the heat of the hot-water pipes unless they are close to the stems of the plants; if 6 inches distant from the pipes the stems of the plants will be quite safe.

Names of Plants (*J. Luck*).—Adiantum capillus-Veneris and Adiantum Farleyense.

POULTRY, BEE, AND PIGEON CHRONICLE.

BROODY HENS.

We fear good chickens at the early chicken shows will be very scarce this season. We never remember such disastrous accounts from our friends of their early chickens as we have had this year. From all we receive these reports, and these from all over England. One gentleman of wide fame writes from Lancashire, "We have had a terrible winter and lost many valuable birds, and have not a chicken." Another writes from Devonshire, "We have never had such a winter, we are all behind," and from Kent, Surrey, Suffolk, Shropshire, and other counties come the same bad tidings. Some attribute the failures to the severity of the weather, others to the want of eggs, a third party to its being such a bad hatching season, but the large majority assign as the cause being unable to procure broody hens. There are exceptions to every rule, and so here, for we saw the other day two honny lots of 1875 Malays, and we hear of a few Dorkings at Early Wood and Micheldever, and of Brahmas at Creeting, and Black Cochins at Baschurch, but still these are the exceptions, and the rule is a total failure in early chickens.

There is plenty of time yet for those who, like the worthy Stoke Park manager, do not go in for early chicken showing, but in the yards of those fanciers who do usually support such exhibitions we hear of a perfect absence of 1875 chickens, and this, as we said before, principally from the want of broody hens. We know of one gentleman who has offered in his neighbourhood 10s. each for sitting hens and offered in vain. Really an exhibitor needs to keep a stock of an hundred or so birds for sitting purposes, only to ensure broody hens in the early year.

We conclude it is in consequence of this great demand for sitting hens, which increases yearly, that the "broody hen trade" as we will term it, seems to thrive so well in places: we repeatedly see advertised "broody hen, china egg, nest and all for 5*s*." This sounds charming, and we know of two parties, unknown to each other, though well known to us, who answered such an advertisement, and enclosed 5*s*. and ordered the sitting beauties to be sent forthwith. The baskets came with the china eggs and the nests, and the hens are there, but they are not broody! And they look as if they had not laid an egg for a month, or were likely to do so for two or three more to come. This happened in both cases. One of the purchasers in a fit of indignant anger wrote to the vendor and complained, saying the hen would not sit, and had never wanted to sit! To him came back the cool reply, "Sometimes I find they do fail, so I return you 1*s*. in stamps." And, N.B. the man had got 4*s*. for a hen who had doubtless had many a brood, but would not have another for many a long day to come, and which would be very dear to buy at 1*s*. 6*d*.

We mention this to show that all those tempting offers in cheap advertisements are not to be accepted. We do not say but that many of the hens advertised do want to sit when sent away, and do sit when they arrive, and sit well. We know of one gentleman who has bought such and done well with them, but we cannot think the plan a satisfactory one, and it makes us long for an incubator warranted to hatch. We wonder if there ever will be such. When we say warranted, we mean of course, provided all ordinary trouble and care are taken. Mrs. Cheshire has shown us how to take care of the chickens when we have them by her most ingenious and simple apparatus. Now we want someone to show us how to hatch them. We are fully aware that during this season new incubators on simpler principles have come out, but we have not heard of anyone who has been really successful with them. When we say successful we mean for six or seven eggs out of every dozen to hatch. We feel it would be a real boon, a real benefit to the fancy, for some incubator to be introduced which will bring about with ordinary trouble and care the desired end. We have tried incubators, and our friends have tried them, but always without real success. We have had them or seen them in use from many makers, and burning everything conceivable from paraffin oil down to night lights, but always without success, and yet those who have tried them are really practical people, who have spent much time and money over them. Talking of incubators, however, as an example of how very foolish some people must be, we heard of one lady, and know it to be a true story, who had just been taken with the fever, and hearing of an incubator, or as she called it a hatching machine, sent for one, and on its arrival placed eggs in it with the greatest possible zest, and expected thereby to do away with the tedious period of three weeks' incubation, and that the eggs would hatch out at once by machinery! This may seem incredible, but it is true. It is a parallel case to the gentleman who bought a Carrier Pigeon, tied a good thick letter to its wing, and having whispered to it to fly to his wife in London (he was at Ramsgate) let it fly!—W.

HOUDANS AS LAYERS.

My experience is something similar to "D., *Deal's*."

On April 5th, 1873, I hatched a brood of Houdans, out of these I had three pullets. I had the first egg from these on the 13th of December, and I had eggs constantly from these three pullets up to September 27th, 1874. The three pullets averaged in this time about 120 eggs each. They then began to moult. Last spring I bred from these three pullets and a cockerel (not related), two broods of chickens in April. Out of these I had about eleven pullets. I had the first egg from these on November 6th. From November 6th to December 27th I had thirty-six eggs, and then they left off altogether until January 25th, 1875. Since then up to this date (March 5th), I have had seventeen eggs.

The two-year-old hens that I have spoken of as averaging last year 120 eggs each, have never laid since they left off to moult. They have an enclosed grass run, and are fed on good barley and a feed of scraps and pollard every now and then.

I may say that I have now only four of the pullets and two of the two-year-old hens, having parted with the rest on account of their bad behaviour.

I have a pen of Black Hamburghs which I bought about Christmas time (a cockerel and two pullets). These began to lay on February 7th, and since then I have had seventeen eggs from them. I also know a person who has some Black Spanish and also some common hens in full lay, despite the severity of the weather.—Edward Smith, *Maldon*.

THE EXHIBITION DORKING.—No. 12.

BY T. C. BURNELL.

The Silver-Grey Dorking is really a beautiful variety, and combines the useful points of the Dark Dorking with most attractive plumage. It is to be regretted that this breed is so little patronised, as I am sure no other purely fancy breed can compete with it where fowls have to find their own food; nor do they ever look to greater advantage than when working hard for their living in a hedgerow or homestead.

The shape of the *Silver-Grey Dorking cock* differs in no respect from that of the Dark Dorking: the difference is solely in the colour; and as this is a fancy breed, colour is of greater importance than in the Dark variety. The comb of the Dark Dorking may be either double or single, but the comb of the Silver-Grey must be single. This is well recognised, though I have never seen it mentioned. The plumage of the Silver-Grey cock must be solely of black and white feathers, any red or parti-coloured feathers being a disqualification. The neck hackle should be a clear white, but a slight pencilling of black down the centre of each feather is allowed, provided it does not produce a dark

appearance. The back, shoulders, saddle, and saddle hackles should also be of a pure white, while the breast, tail, and thighs should be black, any white in these parts being a disqualification, except on the thighs, where a little grizzling in an old bird will pass. The black wingbow should be cleanly cut, and this makes a pleasing contrast to the white of the remainder of the wing.

The plumage of the *Silver-Grey hen* is exceedingly pretty, the whole of the body feather and wings being of a clear silver-grey colour, while the breast is a rich robin red. As in the Dark Dorking, the shaft of each feather should be distinctly white, only in the Silver-Grey variety this should not extend to the wings and shoulders, or it rather spoils the general appearance. The neck hackle should be white, with a narrow and distinct black stripe down each feather.

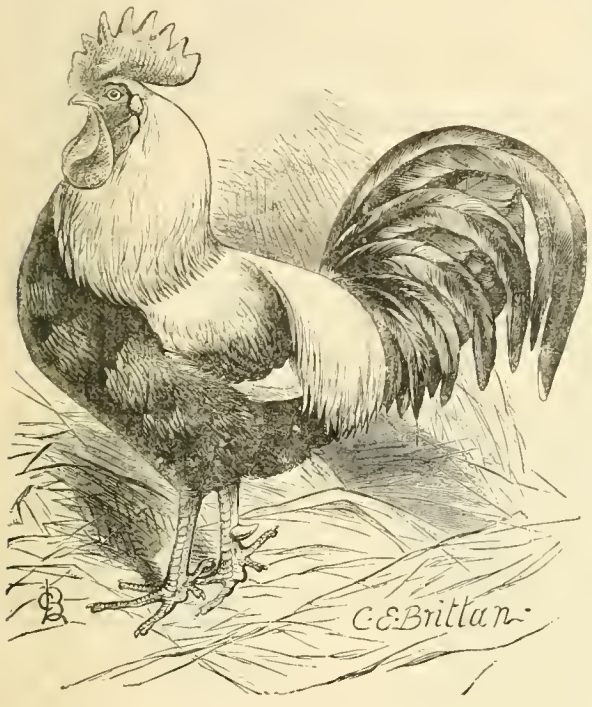

Fig. 53.—Silver-Grey Dorking Cock.

Although good Silver-Grey hens are by no means easy to breed, the cocks are far more difficult to obtain perfect; and I often think when I see judges withholding prizes in the Silver-Grey classes while they give prizes to Mealy Cochins and White-throated Brahmas, that they do not make due allowance for the very great difficulties which Silver-Grey Dorking breeders have to contend against.

By far the worst point in a Silver-Grey cock is a yellow hackle or saddle; it spoils the whole beauty of the breed. The smallest speck of white in the breast of the cock or in the tail is considered a disqualification, though I would far rather see this than a yellow hackle. The back and shoulders must be free from red or chestnut feathers: this is positive. The earlobes should be red.

The defect most difficult to avoid in breeding the Silver-Grey hens is a rustiness or dullness of the plumage, especially on the wings. Birds showing this defect should be avoided either for breeding or the show pen, as cocks bred from them would be sure to breed rusty-winged pullets. I should not discard a bird altogether if large and only slightly ruddy on the wing, as this will wear away a little with age, but a white breast or tail in a cock will infallibly become worse with the moult.

The Silver-Grey Dorking seldom or never attains the size of its darker brother; but cocks of 10 lbs. in any breed are quite large enough for all useful purposes, and I should be glad to see the judges look more to feather, shape, comb, and feet than to mere size. "Sooty feet" are not uncommon, and they must be carefully avoided. I have seen it remarked that the "sooty" feet now so common in Dark Dorkings have been caused by the overbreeding for dark feather; but if so, how is it that dark feet are quite as common with the Silver-Greys?

To breed Silver Greys perfect birds must be obtained, though they be small, and the importance of obtaining cocks of a good strain cannot be over-rated. Birds of different strains sometimes produce very badly-coloured chickens if the two strains do not amalgamate or "nick," as it is called; and in commencing a strain it will be far better to procure the cockerels and pullets from the same yard, and afterwards to buy hens of the correct colour to cross with, as by this means size may be kept up with less danger of the whole yard being spoilt.

To obtain early chickens it will be necessary to breed from cockerels, as I have found from painful experience that two-year-old cocks are not to be trusted till the warm weather appears.

The Red speckled Dorking is now almost obsolete, having given way to the more fashionable Dark and Silver-Grey varieties. Specimens may still be seen in the farmyards of Surrey and Sussex, but of no great excellence.

The principal peculiarity is found in the hens, which are of a brown or chocolate colour, spangled all over with distinct white spots as large as a large pea, giving them the appearance of having been out in a fall of snow. This colour is I think more curious than attractive. Cocks to match such hens should have a good deal of red and chestnut on the back and shoulders, their breasts should be spotted with white or red, and white in the tail is not objectionable. I believe they are a hardy breed and very readily fatten.

HULL SHOW OF PIGEONS, &c.

The first Show, which is proposed to be annual, was held in the Albert Hall in Hull on the 11th and 12th inst. Financially it was a rare success, and the visitors were very numerous. The room was small, but the most was made of it; yet there was not much space for visitors. The animals were well attended to, and fed with correct food except the cats, which had each a portion of raw bullock's lights, to which we would draw the attention of committees, this being the most indigestible of food, and smells disgustingly, and is generally voided; while if well boiled it is an excellent diet for them while in confinement. This can be easily excused, as the management of the cat in the show pen is scarcely understood as yet.

Pigeons were first on the list, *Pouters* taking the lead. These classes, though containing some good birds, were not good as classes. In Blue or Black, Mr. Nottage won first with his grand Blue cock; the second, a Blue hen, being also very good in style and limb; third a large Blue cock. In any other colour the first was a large bird, capital in style and shape, but very bad in colour (Red); second was a stylish White cock of last year; but we thought that gentleman ought to have taken third with his White hen in place of the Red cock to which the award was made, the latter bird being very shaggy in appearance, and altogether out of condition, although said to show well in a large pen. In *Carrier* cocks the first was a Black, good in style and beak wattle, but bad in eye wattle; second a good all-round bird, but not so heavy; third Dun, but rather broad-skulled; and extra third Black. In hens Mr. Yardley won with a grand Black; the second going to a Black almost devoid of beak wattle, but good in eye; the third much better, but rather spouty. In *Barbs* (Black) we did not agree with the awards, the winners being very spouty in eye and in bad order, except the second-prize bird, which we should have placed first. In the next class equal firsts were awarded, but we had no hesitation in marking the best of the two (Baker) Yellow; second should have been Mr. Spencer's Dun. Mr. Yardley won third with a capital Yellow hen. In *Owls* the English were passed entirely unnoticed, the preference being given to the foreign variety. First was a very small White; second a large Blue, with a perfect head; third White, and good extra white as well; but one of the best, a neat Black, shown by Mr. Shillitoe, was passed unnoticed. This bird would not have been wrongly placed if the first award had been made to it. *Turbits* were a fair class, the first going to an excellent Silver; second to a White one, superb in all Turbit properties except colour, and we must confess we never saw a White one admitted in good competition before as the leading property seems to be altogether lost. Third was a Silver, but not as good as some others in the class, particularly a Red shown by Mr. G. S. Stephenson. *Jacobins* not a good class, first a capital Red; second White, but coarse; third Red, and good all round. In *Tumblers* all were noticed, and were a capital class, first was a Kite, perhaps the best in existence; second Mr. Yardley's Almond cock; and third a good Agate, all well placed. *Fantails* were good, the first about perfection; second a fair bird; third Blue, good in carriage, but tail too narrow at bottom. The awards in *Antwerps* were not in accordance with our experience, the first was a Blue medium-faced cock, with a sandy eye, a bad fault; second a good Short-face, except that his colour was two mealy and bars bad; the third, a Blue cock, had a small frill. In our opinion the first ought to have gone to Mr. White's Silver Dun Short-faced; second to Mr. Stanley's Red Chequer ditto; and third to Mr. Yardley's Silver Dun. *Dragoons* were almost all of the London Fancy, three of the four awards going to Yellows, and one to a Blue, all well placed from the London stand-point. This was a large class. In the Variety class the first was a perfect Archangel; second an almost equally good Grey Frillback; extra

second a grand Trumpeter; and third to a good Blondinette. This class was thoroughly well judged. Two Selling classes containing upwards of eighty entries wound up this section. There were five pieces of plate awarded as point prizes, and the whole were won by Mr. Baker.

Eleven classes, with four pieces of plate, brought together a splendid entry of RABBITS; but unfortunately the awards were not made by the advertised Judges. In the first case we know not why, but in Mr. Allison's case through serious indisposition. In *Lop-eared* Bucks Mr. Boden was rightly placed first with his Black, which was second at Northampton, and which has mightily improved since that time; length 22¼. Second was a good Fawn-and-white, 22¼; third a thoroughly crooked-legged Rabbit, Tortoiseshell; and extra third a Fawn, 22 inches measurement. In Does Mr. Irving won both first and third with Black-and-whites, the first taking the cup also, this being a little short of marking, but a really grand Rabbit, ear 23 inches; the third being 22½ and better in marking, we thought should have been placed before the second, which, though a grand Rabbit, wants condition. Mr. Cranch showed a Black-and-white, which we thought should have been noticed. *Angoras* were a good class, and Mr. Swetman beaten with an excellent Rabbit quite as large and much finer in fur; the third going to a small but well-woolled animal. *Silver-Greys* were a bad class, although the prize Rabbits were good; but it is quite certain that Mr. Firth's buck, which has attained fine condition, should have been first, and Mr. King's second. Mr. Hallas won three thirds, the silvering of the bodies being good, but the heads a little too dark. Mr. Hudson's buck (not for competition) spoiled the lot. *Belgian Hares* were a good class, and the awards well made. Any other variety followed with a very pretty so-called Siberian (which is neither more nor less than a cross between the Himalayan and Angora) first, and Silver Creama second and third. *Dutch* were next, with Black-and-white (rather large) first and cup; a small neat Blue second; third Blue; and extra third Black. *Himalayans* were a good class, and the winners pretty well chosen, the Secretary purchasing and awarding an extra himself to the first, although we confess a preference for the second-prize Rabbit; the third also very good. There were two Selling classes, and some good Rabbits shown, the special going to a capital Fawn-and-white buck. In the next class the first was a Silver-Grey; but this was nothing nearly so good as one shown by Mr. Hincks, nor that by Mr. King, and should not have been in the list; second was a nice Angora; and third Belgian Hare.

In CATS there were no entries for Tortoiseshell. In Any other variety the Tabby Lion was placed first, but was evidently ill at ease in his den; second and third were also Grey Tabbies, but in marking, which we understood to be the point expressed in the schedule, the third was far ahead, although the first was beat in other points.

POUTERS.—*Blue or Black.—Cock or Hen*—1 and *c*, W. Nottage, Northampton. 2, J. Baker, Kew Bridge. 3, H. Yardley, Birmingham. *vhc*, J. Baker; H. Severs, Middlesborough. *hc*, J. Baker; P. R. Spencer, Hereford; W. Nottage; J. Richmond, Accrington; R. H. Blacklock, Sunderland.

POUTERS.—*Any other colour.—Cock or Hen.*—1 and *c*, J. Baker. 2, J. E. Spence, Broughty Ferry. 3, T. Wood, York. *vhc*, A. Spencer, Driffield. *hc*, W. Nottage (2); G. Robinson, Sunderland; L. & W. Watkin, Northampton.

CARRIERS.—*Cock.*—1, 3, and *vhc*, J. Baker. 2, H. Yardley. Extra 3, H. Yardley; P. R. Spencer. *hc*, B. Hudson, Driffield; P. R. Spencer; R. H. Blacklock. *c*, F. Hodgson, Driffield; W. Blacker, Hull. *Hen.*—1 and *vhc*, H. Yardley. 2 and 3, P. R. Spencer. *c*, F. Hodgson; J. Baker.

BARBS.—*Black.—Cock or Hen.*—1, J. Stanley, Blackburn. 2 and 3, H. Yardley. *vhc*, J. C. Adams. *hc*, W. Brydone. *c*, J. Baker; H. Crosby; J. C. Adams; G. W. Dutton; J. Holden.

BARBS.—*Any other colour.—Cock or Hen.*—Equal 1, J. Baker; J. E. Spence. 3, H. Yardley. 2, J. Stanley. *hc*, J. Baker. *c*, J. C. Boothby.

OWLS.—*Cock or Hen.*—1 and Extra 3, G. Anderson, West Hartlepool. 2, C. N. Lythe, Cottingham, Hull. 3, J. Baker. *vhc*, J. Baker (2); J. Stanley. *hc*, J. C. Adams; R. Shillitoe. *c*, J. Baker.

TUMBLERS.—*Cock or Hen.*—1, 2, and 3, J. Baker. *vhc*, W. Brydone; T. S. Stephenson (2); J. Baker; E. A. Thornton. *hc*, C. N. Lythe; C. W. Washbourne; E. Heath. *c*, W. R. Rootes.

JACOBINS.—1 and 2, J. Baker. 3, T. Holt, Bradford. *vhc*, W. Brydone; G. E. North; T. Holt. *hc*, J. Baker (2); J. Banks. *c*, W. Nottage.

TUMBLERS.—*Cock or Hen.*—1, J. Baker. 2 and 3, H. Yardley. *vhc*, J. Baker (2); R. Minnitt. *hc*, H. Yardley; J. Stanley; J. Baker. *c*, W. Brydone; G. Holloway.

FANTAILS.—*Cock or Hen.*—1, A. Smith, Broughty Ferry. 2, S. Lawson, Preston. Extra 2, J. Warhurst, Stalybridge. 3, J. Walker, Newark. *vhc*, J. Baker; J. E. Spence; T. & W. Peirson; J. Warhurst. *hc*, J. C. Boothby; J. F. Loversidge; J. Baker. *c*, J. C. Boothby; J. F. Loversidge; J. Baker.

ANTWERPS.—*Cock or Hen.*—1, G. Blakey, Driffield. 2, R. White, Manchester. 3, F. Eastwood, Littleborough. *vhc*, H. Yardley; J. C. Boothby; H. Yardley; R. White. *hc*, H. Yardley; C. Jackson; J. Cowley; J. Stanley.

DRAGOONS.—*Cock or Hen.*—1, J. Baker. Extra 1, H. Yardley. 2. Extra 2, and 3, R. Woods. *vhc*, J. Baker; J. Richmond. *hc*, A. McKenzie; R. Woods (2); J. C. Boothby. *c*, J. Baker; J. Stuttard; H. Crosby; G. Hart; D. Maynard; R. Woods.

ANY OTHER VARIETY.—*Cock or Hen.*—1 and Extra 2, H. W. Webb, Lower Sydenham (Archangel and Frillback). 2, J. Baker. 3, E. Heath, Blackburn. Extra 3, H. Yardley. *vhc*, H. Yardley; G. F. & W. R. Umpleby (Red Priest). *hc*, H. W. Webb (Magpie); J. Richmond. *c*, E. W. & S. W. Anderson (Archangel); J. Baker; H. W. Webb (Pigmy Pouter); J. Banks (Magpie).

SELLING CLASS.—*Cock or Hen.—Price not to exceed 25s.*—1, P. R. Spencer. 2, J. W. Harling, Burnley (Barb). 3, J. Baker. *vhc*, W. A. P. Montgomery (Trumpeter); W. Brydone (Owl); J. Nottage; J. C. Adams; H. T. Hincks. *hc*, H. Yardley; J. Baker (2); J. Nottage; J. Banks (Red Swallow); W. Dugdale; E. A. Thornton (Almond). *c*, T. & W. Peirson (Tumbler); E. A. Thornton (Red Jacobin).

SELLING CLASS.—*Price not to exceed 50s per Pair.*—1, L. Allen, London Road, London, S.E. (Black Beards). 2, H. Yardley. 3, W. A. P. Montgomery, Belfast (Yellow Owls). *vhc*, L. Allen (Yellow Owls); J. Baker; G. W. Dutton (Yellow Barbs); G. Stephenson (Tumblers). *hc*, H. Crosby (White Dragoons); W. Brydone (Tumblers); G. Deatner (Tumblers); J. Nottage (2); G. Stephenson (Magpie, Fantails, and Nuns); R. Stabler; R. White. *c*, J. Walker; G. E. North; J. Baker; H. T. Hincks; J. W. Harling (Pigmy Pouters).

RABBITS.

LOP-EARED.—*Buck.*—1, Dr. Bodeo, West Hartlepool. 2, Mrs. H. Pickworth, Spalding. 3, T. Schofield, Manchester. Extra 3, J. Ashley, Hull. *hc*, T. Schofield, jun. *c*, J. Falldiog. *Doe.*—Cup, 1, 3, and *hc*, J. Irving. 2, Dr. Boden. *c*, C. King.

LOP-EARED.—Special 1, T. Myton, York. 2, T. Schofield, jun. 3, J. Wharton, York. *hc*, J. Hallas; A. Canty; J. Wharton. *c*, J. Graham.

ANGORA.—1, A. Atkinson, Huddersfield. 2 and *hc*, H. Swetnam, York. 3 and *c*, J. Hallas, Huddersfield. Extra 3, W. Russell.

SILVER-GREY.—1, C. King, Henry Street, London. 2, J. Firth, Leeds. 3, J. Hallas. Extra 3, J. Hallas (2); J. H. Brand, Bartoo-on-Humber. *hc*, F. J. Allpress; A. Canty; T. Schofield. *c*, B. Greaves; R. A. Bossier.

BELGIAN HARE.—1, B. Greaves, Cleethorpes. 2, J. E. Pilgrim, Hinckley. 3, J. Hallas. Extra 3, G. C. Livett, Soham. *hc*, T. H. Dows. *c*, J. Hallas; G. C. Livett.

ANY OTHER VARIETY.—1, B. Greaves (Siberian). 2 and 3, J. Hallas. *c*, J. Boyle (Silver Cream).

DUTCH.—Cup and 1, B. Greaves. 2, W. Donkin, Driffield. 3, Mrs. H. Pickworth. Extra 3, A. Lund, York. *c*, T. Schofield, jun.

HIMALAYAN.—1, G. C. Livett. 2, A. Atkinson. 3, J. D. Eames, Great Driffield. Extra 3, T. Garner, Northampton. *hc*, C. G. Mason, Rochdale. *c*, J. Pickworth.

ANY OTHER VARIETY EXCEPT LOPS.—1, A. Whitehouse, Northampton. 2, H. T. Hincks, Leicester. 3, G. C. Livett (Belgian Hare).

LOCAL CLASS.—1 and 2, J. Ashley. 3, W. Russell, Hull. *hc*, A. Wokes.

CATS.

ANY VARIETY EXCEPT TORTOISESHELL.—1, G. Baxter, Bath Place, London. 2, J. Halleoby. 3, Miss Shepherd, Hull. Extra 3, J. Platt, Hull. *hc*, H. Witty. *c*, W. Lumb.

Mr. Dobson judged the Lops, and Mr. Fletcher the other varieties.

PRESENTATION.—On the 11th instant the members of the Newcastle-upon-Tyne Poultry, Pigeon, and Canary Show and a few friends presented Mr. H. O. Blenkinsop with a testimonial, consisting of a beautiful marble timepiece, with the following inscription:—"Presented to Henry O. Blenkinsop by the members of the Newcastle Poultry, Pigeon, and Canary Show for his past services as honorary secretary."

OWL PIGEONS.

"WILTSHIRE RECTOR" in your Journal of the 25th makes out as good a case as is possible for his favourites, but still to me it is not convincing. The main point is still untouched, What is an English Owl? Is it a fancy bird with a standard of its own, or is it a coarse form of the genuine high-bred bird?

As there is no standard we must conclude that it is the latter—that is, a bird bred halfway to excellence, and then its admirers for some reason I cannot imagine come to a stand and say this is our favourite. I will not dispute that they are not beautiful birds (I cannot conceive of Pigeons being otherwise), but as there are degrees of beauty I contend that they would be much more beautiful still by endeavouring to rival the foreign birds.

"WILTSHIRE RECTOR" says they were beautiful birds a hundred years ago. I have no doubt of it, and that they were also finer in Owl points than the English birds of the present day. How the foreign bird might be considered as the degenerate form I cannot think. If so, then one might think of the English Carrier as a degenerate form of the old Horseman.

As to colour, if we look at the gentle expression of the fine white foreign birds and their equally gentle retiring ways, I think no colour so suitable as white, as it gives the idea of purity and innocence so fully. The blue birds lose half their charm by their colour. There is wildness in their appearance from the dark beak that tells greatly against them.

The powder blue the old writers do not say a word about; but admitting that they had mentioned them, no good fancier would sacrifice other far more valuable properties for it.

Next to white, I should say that a genuine yellow would be the most beautiful if good in other respects. Eaton says in one of his quaint notes that "the Owl does not derive its name from colour." He also says it ought to "rank third among the Toy birds." Not in the least too high for its merits.

Before leaving colour I may state that the so-called powder-blue colour is of very recent introduction in Owls. I have a confused recollection of an article that appeared in your Journal I think, less than twenty years ago, describing how it was first produced. The late Mr. M. Wicking of London was one of the parties concerned, but I cannot recollect particulars. However, I am convinced that nothing can equal the fine white Owls. They look like creatures not of this earth and yet are on it.

The case of the flying Tumbler and the Almond I do not think analogous to that of the Foreign and English Owls. The Tumbler, if we want tumbling birds, must be kept in its original form, and this is the great point in those birds. The Almond, on the other hand, is not meant for flying or tumbling, it is a mere fancy to show the breeder's power over form and colour, and this power is here made strikingly manifest, it is quite out of the way; whereas the Foreign and English Owl is only a halfway difference. Instead of the common Tumbler and Almond, I would say that the English and foreign Trumpeters make a case quite analogous to the Owls, though no one

has yet openly espoused the cause of the English bird; it is quite as good in its way as the English Owl.

"Wiltshire Rector" says the English bird can make good use of its wings, and so can the foreign when flown, which I have done. I am, therefore, still of the same opinion, that to give prizes for English Owls is only offering a premium for mediocrity. In a general way I am not for "furrin" things or ways, but here we are beaten by those whom in our national conceit we look upon as barbarians, or something not far off that etate. They have given us a lesson in the fine arts (for such I hold high-class fancy Pigeon breeding to be), that we ought to profit by.—Bubo.

THE PRIZE CAGES AT THE CRYSTAL PALACE BIRD SHOW.

FIRST-PRIZE CAGE.

The Judges were unanimous in their selection of the cage 1465, exhibited by Mr. Thomas Alwin of Deptford. It speedily met with their entire approval, owing to its adaptability for the show room not only during the daytime but during gaslight, the wire construction of it, especially at the roof, allowing sufficient light to enter the cage and the bird not being shaded, as in the ordinary box cages now generally used. Being of a compact shape and handy size, similar to the cages in use, it may easily be packed. One very ingenious advantage is in the construction of the receptacles for seed and water, which are made to fit in the woodwork on each side of the cage, with mouthpieces or cups the size of the first joint of the thumb to enter each side for the bird to supply itself with seed and water. This is shown by the engraving *a* (fig. 59). The one for seed has a square hole at the top part, by which the receptacle is supplied with seed; and it is calculated to hold sufficient seed for one week for a single bird. The receptacle for water has no hole in the upper part, it being necessary that it should be kept air-tight. When the latter has to be supplied with water it has to be detached and filled at the mouth where the bird drinks from. Altogether it is well adapted to meet all requirements. It is 12½ inches in length, 12¼ inches in height, and 5½ inches in width. The cost is stated to be about 2*s.* 6*d.*; but even supposing it to be a trifle more, it would well answer the purpose required. This cage was awarded the silver medal, and is well suited for most small birds.

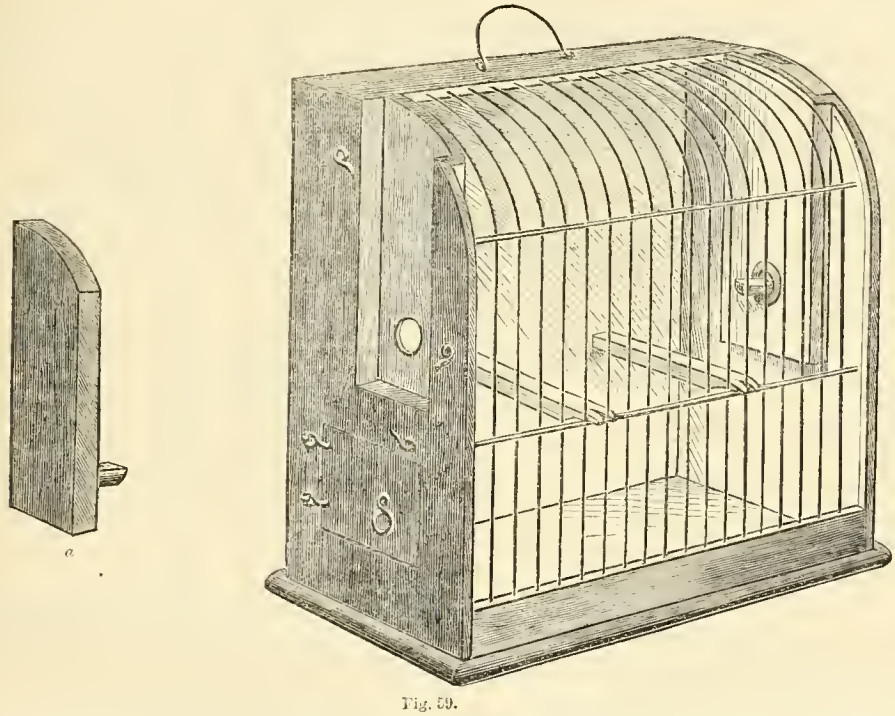

Fig. 59.

Action for Prizes at a Poultry Show.—*Whiteley* v. *Harvey and Others.*—This was tried in the Sheffield County Court on the 13th inst. The plaintiff, William Whitely, of Clough Place, St. Mary's Road, sought to recover the sum of £2 5*s.* from Messrs. W. Harvey, Edward Brown, W. W. Renton, and A. Silvester, the Committee of Management of the poultry Show held at the Bramall Lane Cricket Ground in July last, the money being the amount of first and second prizes in the classes for Brahma fowls. Plaintiff exhibited ten pens of Brahma fowls at the Show, and obtained prizes amounting to £2 5*s.*, which the defendants had refused to pay him. In defence it was contended that the plaintiff had forfeited his prize money because he had infringed the regulations of the Show by purloining eggs produced by the fowls of other exhibitors. Plaintiff denied the offence of larceny, and said he had taken no eggs except those which had been produced by his own fowls. The Judge did not consider there was anything in the regulations of the Show to entitle the Committee to withhold the prize money from the plaintiff, and therefore he gave a verdict for the amount claimed. He thought the defendants had accused the plaintiff with larceny in an unfair manner, and was of the opinion that the charge ought either to be withdrawn or prosecuted.

THE NORTH BRITISH AND THE SCOTTISH ORNITHOLOGICAL SOCIETIES.

In your issue on March 11th, Mr. Huie makes a very incorrect statement, which, as an office-bearer of the North British Columbarian Society, held in Glasgow, I feel it to be my duty to correct. He states "that the North British Columbarian Society is only the remains of the Scottish Ornithological, which was the original name, and only after he and Mr. Ure left it (they were the last of its members) the name was changed to the North British Columbarian." Having acted as Secretary for ten years to this Society from its origin, Mr. Huie will allow me to refresh his memory. The North British Columbarian Society was formed early in the year 1862, nearly two years before the Scottish Ornithological ceased to exist; and Mr. Huie, by turning to the list of prizes awarded at the competition held by the Scottish Ornithological in 1863, will find in print a presentation of silver plate from the members of the North British Columbarian, as a Society, to be competed for as extra prizes.—James Ruthven.

[The Mealy Pouter has now been lost sight of in these letters and it scarcely needs disputing whether one society was born before another was defunct.—Eds.]

CAUSE OF HONEY CANDYING.

A correspondent of "The Scientific American" has been experimenting to prevent honey candying, and states his experience as follows:—During the past autumn I have experimented as follows: I put up six 1 lb. cans of beautiful linden honey, being careful to make it into one homogeneous mass by stirring. It was thrown from the combs by an extractor on

July 20th, and put into cans on August 1st. The cans were placed respectively as follows:—One in a dark dry cellar, one each under shades of red, yellow, green, and blue glass, and the sixth can in full light. On November 8th the honey in the cellar candied to a white. November 22nd to December 10th honey under coloured shades candied, first in the red, next in the yellow, green, and blue; while the honey in full light remained transparent until January, when it soon candied, after exposure to intensely cold weather. From my experience an equal temperature would preserve certain kinds of honey, while other kinds would candy under almost any circumstances.

I think that candied honey, instead of being looked upon with disfavour, should be recognised as evidently pure. I hope, however, that the above experiments will lead others to follow up the light theory with beneficial results.

THE HUNNY BEE.

BY JOSH BILLINGS.

The hunny bee iz about 10 times the size of the hous fly—i never meszured them—they won't stand still long enuff, but i think i hav got their dimenshuns about right.

If i hav made a blunder in this matter i am ready to repent and be forgiven for it.

They are as bizzy as a type-setter on the *N. Y. Weekly*, in thoze countrys where hunny iz skarse, but where sweet meats are a drug they wont work at all.

I dont kno az we kan blame them for this, for if beefsteak lay hot and well buttered bi the roadside all the time, and bivalves were running aronnd on the half shell, peppered and salted, crying "Who will eat me?" i would like to see the man yu could hire to thrash out rye that was wet in the bundle for 10 shillings a day.

Hunny bees are built with a sting, which is quicker than a ghost when a good bizziness chance offers; but i never knu one to use it just for the devilтry ov the thing.

Theze little workers travel about five miles a day during the sweet seazon, and bring their hunny home stuk unto their legs. If thare is a lazy one in the hive he gits lynched at once. Lynch law iz the hunny bee's justiss.

Man stole this code from the hunny bees, just az he haz stole pretty mutch everything else he haz got.

Killing oph the lazy may look a little tuff, but after all thare is sumthing like mercy in it, for it iz the only way knowu az yet to put an end to their torments.

Hunny bees have a queen, but never a king; this iz a grate kompliment to the sex, and iz an argument for *Wimmin's Rights*," which the beleavers in this doktering are welkum to use without giving me kredit for it.

The hunny bees are the only nation i kno ov who have allways had a queen for their ruler, and who hav been more prosperous and have existed longer than enny people we kno ov.

I luv the hunny bees bekauze they are allwuss bizzy, and hav a stinger allwuss hot and reddy for the lazy, and for those who poke their noze into their bizzuess.—(*N. Y. Weekly.*)

"The Handy Book of Bees."—The second edition of Mr. Pettigrew's book is just published. Its object is to show how they may be kept profitably. He says in the preface—"In bee-keeping I reckon the question of profit is of first importance. Stings do not seem half so painful to the man whose annual proceeds of bee-keeping amount to £10, or £20, or £50. It is my desire, therefore, in this work to show how bees may be kept with both profit and pleasure. In addition to the profits of bees there is a fund of interest and enjoyment derived from keeping them, uplifting in its nature and tendencies."

OUR LETTER BOX.

Rump Abscess on Fowls (*Poultry-keeper*).—You have been feeding your fowls wrong. They have had heating food and are suffering from it. Your first treatment must be a table-spoonful of castor oil to each. Wash and foment the vent and hinder parts with hot (not scalding) water. After you have done so, if you find a cheesy tumour, which you may in some of them, you may disperse it by squeezing, or it will perhaps force its way through the skin. In this latter case wash it out with a sponge and warm water, and draw the lips of the opening together with a coarse thread. When you have done so, rub some ointment into the aperture, covering the stitches. Feed on ground oats or barleymeal mixed slack. All that have suffered will require to be watched for a day or two.

Egg-eating Fowls (*E. C. O.*).—It is generally believed and we think so, the eggs are first eaten for the sake of the shell, in consequence of the absence of the necessary material from the haunts of the fowls. If they have no access to lime, throw down a barrowload of bricklayers' rubbish for them. If they are in confinement give them some heaps of fresh-dug mould. If it has grass among it so much the better. This tiresome habit is generally begun by one bird, but the others soon learn it. If only one or two have acquired the vice they may be detected by close observation, as after their cannibal's meal they generally have some of the yolk sticking round their beaks. Remove them at once. It is a good plan to watch the hens when they go to nest, and to drive them off as soon as they have laid. Another plan is to put some hard composition eggs in the nests, and to let one or two lie about on the run. They get tired of pecking at them. As a rule, fowls at liberty seldom eat their eggs unless a hen drops one without going to nest, they will then run at it. Whether confined or not they are not half so much given to eating eggs that are laid in nests as those that are dropped about.

Weight of Houdans (*Jane*).—A thorough-bred Houdan cock may weigh from 8 to 10 lbs. We hear of them weighing 12, but have never seen one. A cock weighing 9 lbs. is a good one. Hens about the laying time will weigh 7½ lbs. If you have these weights you may rest and be thankful.

Canary (*M. F.*).—The box was smashed and nothing in it. Certainly no sigas of tapeworm.

Two Hives of Bees (*Triceps*).—You wish to get a swarm for a friend out of your two hives, and so manage them as to have no more swarms but plenty of honey. You can easily contrive this. Drive a swarm, as we said before, and having got rid of all the adult bees and sent away the swarm, transpose your hives, putting the denuded stock in place of the hitherto untouched hive. This will equalise the population and delay, if not entirely prevent, after-swarming. Of course the denuded stock will have to raise a queen. Give supers as soon as the bees want room.

REMARKS.

17th.—Dry but very cold day.

18th.—Very bright sunshiny day, but extremely cold wind.

19th.—Damp with very slight rain in the morning; dull day; the wind not quite so cold as yesterday.

20th.—A dull cold day, only a few gleams of sunshine.

21st.—Another dull cheerless day, with but little sun and cold north-east wind.

22nd.—Rather dull early, but very bright afterwards all day; and a most beautifully bright moonlit night.

23rd.—Splendidly bright from sunrise till 4 P.M., then rather less so, and the wind still cold.

Temperature very much the same as last week, but the air much drier, in fact on some days remarkably dry.—G. J. Symons.

COVENT GARDEN MARKET.—March 24.

A moderate supply and prices rather advancing, especially in first-class goods. Hothouse Grapes of good quality are becoming scarce; the only variety now worth notice is Lady Downes' Seedling. Some fine Pines from St. Michaels have lately passed under the hammer, and are extremely useful. Frame Potatoes from the Channel Islands and Rounds from Malta and Goza are coming into general use.

From observations taken near London during forty-three years, the average day temperature of the week is 56.9°; and its night temperature 36.1°.

THE ORCHID-HUNTER IN BURMAH.—No. 1.

SO much has been written, and well written, about Orchids that it seems difficult to break fresh ground and note anything new about them useful and instructive to the horticulturist, to the lover of Orchids, and to all interested in this charming tribe of plants.

The observations of the Orchid-hunter made at their places of growth may, however, prove to be of considerable use both to the professional cultivator and the amateur. The habits of the different species, their situation, the mode in which they grow, the special circumstances of temperature to which they are exposed, their time and mode of flowering, are all matters which the Orchid-hunter has special opportunities of observing; and it is probable that there are still many small points on which the horticulturist remains uninformed, the elucidation of which may furnish valuable hints to all interested in their cultivation. The subject is not one easily exhausted, and a more perfect appreciation and knowledge of these plants and their wants may be gained from observations made on the spot.

The notes on Orchids, epiphytal and terrestrial, will specially include the chief abodes of the different varieties, regarding which more errors are extant than on any other point connected with them—errors partly caused by the people to whom they were first consigned considering them as natives of the ports from whence they were dispatched to England, and partly from the jealousy of the collectors, who were not at all desirous that their Eldorado should be discovered by the general public. A remarkable instance of an error of this kind occurs in that carefully-written and admirable work on Orchids, "The Orchid-Grower's Manual," by Mr. Williams, where it is stated that Cypripedium niveum is a native of Moulmein. Cypripedium concolor, a plant very nearly allied to it, comes from the neighbourhood of Moulmein, where it grows on the limestone rocks; but Cypripedium niveum has never been found there nor in any other part of Burmah. It comes from the Straits of Malacca, and finds its way to Moulmein by the coasting steamers, where it is much in request in exchange for Moulmein Orchids. It is thus that Moulmein has the credit of being the home of this Orchid, one of the most beautiful of the Cypripediums.

A knowledge of the correct geographical distribution of these plants is very valuable to the horticulturist, as from this he gains a good idea of the different kinds accustomed to the several circumstances of climate. In his remarks on Orchids, the description of their haunts and manner of growth, the Orchid-hunter cannot well do better than commence with a description of the Dendrobiums, the most numerous class of all the Burmese Orchids.

The nigro-hirsute Dendrobiums, a genus having small dark hairs on the new growth, and which, as a rule, flower before shedding their leaves, claim early attention, both from their beauty and the sweetness of many of their flowers, and from their not having the objection of being denuded of their leaves during the season of flowering, as is the case with such a large number of other plants of the same genus. All these individually caused a sensation when they were first introduced, and they are still favourites with all cultivators of Orchids.

The special home of Dendrobium formosum is on the hills to the south of the road running from Moulmein to Amherst. They are found sparingly scattered over other parts of Burmah, but here they are in thousands. The first sight that meets the Orchid-hunter travelling down the road to Amherst during the summer months is large baskets full of the flower shoots of this splendid plant being brought into the Moulmein market, where they are sold to the Burmese women to wear in their hair, the market price of each flower spike being about sixpence. Sometimes as many as ten men at a time are seen, each carrying two baskets slung on a bamboo full of these flowers, so that the air along the road is quite perfumed with their scent.

These Dendrobiums almost invariably grow on the Pedonk tree; and besides the two varieties commonly known to gardeners as Dendrobium formosum and Dendrobium formosum giganteum, there is a very distinct variety known in Burmah under the name of Dendrobium formosum Amherstianum. This is a charming plant, more delicate than the two preceding kinds, the yellow in the throat and on the labellum being of a pale straw colour. The racemes of this variety are slender, and the plant is quite wanting in that robustness of habit which characterises the common Dendrobium formosum. This variety is scarce, and likely to continue so, as it is not so easy of cultivation as the other varieties. It grows on the trees near the sea at Amherst, and has not at present been found anywhere else.

All these varieties of formosum grow on the branches of trees in the most exposed situations, subject to the influences of a blazing sun in the summer and to a continual downpour of rain during the rainy season; the rainfall in this part of Burmah averaing 200 inches, during the season.

Were it not for the dews at night during the summer months the plants would undoubtedly die. Thousands of the small seedlings, and some of the larger plants, as it is die every season. This shows that, although this like other Orchids requires a season of rest, it is necessary for the cultivator to imitate the nightly dews during the resting season, which is best done by giving a very slight watering at the roots in the early morning; by this means the horticulturist can not only insure the plant keeping in a robust and healthy condition, but he can improve on the circumstances of Nature by supplying during the scorching months that shelter which the plant does not have in its native jungles.

During the season of growth it is unnecessary to say that plenty of water is essential to its well-being.—E. S. B.

CUPRESSUS LAWSONIANA.

OF the many evergreen trees and shrubs of late years introduced there are none in my estimation so beautiful as

this Cypress. It is graceful in appearance and varied in habit; a close dense evergreen growth prevails in all whether the habit be upright or spreading, the former rising erect like a pointed pillar, while the other sweeps the ground with its semi-pendant arching growth. At no time is it so beautiful as in spring, when aglow with the deep scarlet of its flowers, which are dew-drop-like, suspended by the matchless green of its graceful branchlets. Especially is this the case with specimens which have been transplanted, the removal one year converting its spray into clusters of red the year following.

This leads me to point out its claims as a subject for spring floral display, if not in the parterres at least in such positions where something is required to take off that flat monotony and stiff formality which characterise present attempts at floral effect. As a tub plant it has merits which are overlooked; whilst for large vases, which in the winter months often go empty for want of fitting plants, there is none in all the class of hardy plants that for fitness can compare with a low spreading bush of Cupressus Lawsoniana. Its roots do not suffer in the least from frost. I know one in a tub about 18 inches square and 12 inches deep upon a portico of north aspect which has stood the winds, drought, and cold of the past four years without attention of any kind, and it is now as hale and beautiful as when placed there, a position that would have brought grief to a majority of plants. For vases it may be made to assume a spreading habit by taking out the growths which have a tendency upwards, and selecting those which are decidedly spreading and pendulous, the form known as gracilis being very suitable. For tubs any of the varieties are suitable, and grown in pots for decorative purposes in halls, corridors, &c., it reminds one of a tree-like Fern, having the grace and elegance of those plants without their liability to injury from the draughts of such positions.

It is, however, to its merits as an ornamental evergreen tree or shrub that I wish to direct attention, and may be allowed to say that its introduction to this country dates no further than 1855, its discoverer being Mr. William Murray, who named it in compliment of the spirited firm who purchased the results of his researches amid the vegetation of the Sierra Nevada. Mr. Andrew Murray states, "it was found on the banks of a stream in a mountain valley, growing to the height of about 100 feet. The foliage is most graceful, and the branches hang down at the tip like an ostrich feather, while the top shoot droops like that of a Deodar."

This handsome tree is now plentiful, and its fitness for general decorative purposes in pleasure grounds is apparent in many ways, and in none more than as an avenue tree along the sides of drives and approaches to mausoleums, whilst for churchyards or cemeteries it stands pre-eminent. Its hues are more evergreen than that of the Deodar, and it stands wind better, though the Cupressus Lawsoniana assumes in very bleak positions more of the character of a bush—low and spreading—than a towering tree, yet its aspect is of that grace and elegance which befits its association with monuments, and exhibits an unmistakeable sympathy with the feelings of the spectator. As a lawn tree and in the foreground of shrubberies it stands out in contrast and relief with the trees and shrubs of broader foliage, and contributes an air of lightness to otherwise heavy groups.

As a screen it has no equal in ornamental grounds. Its growth is dense, and is not so liable to split or divide as that of Arbor-Vitæ. It also bears cutting well, and grows quickly, and may be kept of any height or width. Though there are many varieties the plants vary very much in character, both from seed and cuttings. Its diversity of habit is due also to situation. In warm and sheltered places the growth is erect and tree-like, the disposition is to tower upward rather than spread outward, and yet there is no disposition to sparseness of branch and spray at the base. Do not, however, misunderstand me, for I do not intend to convey an idea that it is tender; it succeeds in positions that the Deodar does not, and yet the best growths are made where slight and distant shelter is afforded. In exposed positions it becomes more of the character of a bush than tree, its upward tendency being checked by the winds, and this causes its vertical growth to be slow, and side growth to take place more than in a sheltered situation. It does well in any soil, growing more quickly in light loam than those which are heavy and wet, and delights in a moist station, yet freed of stagnant water in the subsoil.

There are many varieties. Erecta, which grows up a close and compact pyramid, and of this there are two sub-varieties—viz., lutea with yellowish young growths; and glauca, which, as its name implies, has the habit of the species with glaucous foliage; gracilis, slender, and a more drooping habit; nana, a pigmy of the species with very compact growth, and useful for beds in winter; stricta, growing into a fine pyramid, not nearly so bush-like as erecta; argentea, with white variegation, another argentea with very pale foliage, almost silvery; and variegata aurea, with gold variegation. In fact there is a great variety of forms, which, however, are not apparent at a distance, and we have one which I do not see in lists, a perfect balloon shape, and not more than 3 feet in height, and yet not compact in growth so far as relates to nana or compacta, but having more the habit of gracilis.—G. Abbey.

NOTES RELATIVE TO THE POTATO.

I fully agree with Mr. Luckhurst that in investigating the Potato blight we must not take the experience of one year as a basis on which to rest our deductions. In this remote portion of the country artificial manures have not yet come into general use. We have many farmers of the old-fashioned class who are content to work on in the lines laid down for them by their fathers. These old stagers continue to use farmyard manure for their Potato crops, and farmyard manure alone, and not too much of that even. They invariably grow the soundest crops, and I can assure Mr. Luckhurst that what they take up are slightly larger than ordinary marbles.

No man of common sense could be so bigoted as to say that the seasons exercise no influence upon the blight. Where the predisposing agents are already in existence, a wet or dry autumn will cause a greater or lesser blight; but what we all want to find out is the primary cause of the blight. If Mr. Luckhurst's theory of atmospheric cause is correct, then why does he not attempt to show that our climate underwent a change in 1845, and that that change has existed to the present time? On this hypothesis only can I reconcile that theory.

I have not seen the pamphlet he alludes to in his last communication, nor any other treating on the view of over-cultivation. My deductions are based upon experience in observation of the nature of the esculent in question.

Going back to the year 1846, I knew a field in which the two extremes of manuring were in operation. The richly-manured half had scarcely a sound Potato in it, whilst the other half, which had been manured with almost dry, light, farmyard litter, were fairly good. Year by year I have been more and more convinced that in our great anxiety to produce heavier crops we have been working on a suicidal policy, and have killed the goose with the golden eggs. A naturally hardy robust constitution has been fed upon confectionery, pastry, and condiments until its constitution has given way under the strain. Virgin soil may act as a corrective to the invalid, but one year's treatment will not wholly eradicate ills the growth of many, especially when that soil is mixed with the destroying element. That the evil is wide-spread and universal is evident from the fact that offers of large money rewards fail to produce disease-proof seed.

As I said in my first communication, my belief is that in order to effect a cure it will require combined and long-continued effort. To be effectual it must be combined, and a matter which is now troubling our meadows in this division of the country affords me an illustration of the sort of co-operation required. Since the introduction of railways into the Lake country of England our meadows have year by year become more and more infested with the Ox-eye Daisy. Some time ago a writer in the *Agricultural Gazette* called attention to this matter, and said that as the plant was only of three years' growth, and as sheep were particularly fond of it, united action of sheep-pasturing on the part of farmers would soon eradicate the pest. Some acted on the advice, others did not; the seed was carried from the neglected meadows to those of others who were trying to rid themselves of it, and the latter found their efforts futile, and for lack of this co-operation a large proportion of our hay crop is only fit for bedding purposes. For lack of this same co-operation a large proportion of our Potato crop goes to feed our swine, or is utterly wasted.

If agriculturists wait for some specific which will suddenly restore to us sound crops of Potatoes, I am afraid they will be doomed to wait in vain. God helps those who help themselves, and I am confident in the belief that we have the remedy within our hands.

Let us take care that our high-pressure system of farming does not lead us into the same fix with other necessities of

life. The reflection whether we may not behave so well to the land as to endanger our grain and root crops is not so utopian and visionary as some people may be apt to suppose. Already the cry of raking-up subsoils is raised, as though the surface matter was satiated with its feast.

We are doing away with our old system of allowing the earth to recruit exhausted nature under fallow. Are we, or are we not, preparing ourselves for "a famine of the land?" History oft repeats itself, and it may be as well to pause before we have advanced too far, and ask ourselves the question, "Will the soil bear the constantly increasing strain we are placing upon it?"—Beta.

CALADIUM CULTURE.

This beautiful and easily-cultivated genus of ornamental foliage plants has of late years become very numerous and popular.

They should be potted when growth commences, using a compost of two parts peat, one part turfy loam, one part silver sand, and plenty of drainage, and be placed in a brisk bottom heat, and a moist temperature of 70°. By frequent potting theysoon make large plants. Slight shading is necessary during strong sun, yet they should at all times be fully exposed to the light, as too much shade and strong heat produces drawn and thin foliage, so that if removed to a cooler temperature or the exhibition tent they have a flimsy appearance. Syringing is beneficial to these as well as most other foliage plants; rain water should be preferred. We labour under the disadvantage of having to use spring water rising from chalk, and the consequence is that plants present the appearance of having had a sprinkling of whitewash. Sponging is a benefit to such plants as Crotons, Dracænas, &c., as it dislodges insect pests; but it does not do for Caladiums, for it injures the beautiful bloom on the leaves.

When their beauty begins to fade, gradually dry them off by giving less water, but on no account should the soil be dust-dry all winter, or when starting time arrives the bulbs may be found to have disappeared from "dry rot."—G. P., jun.

SEAKALE FORCING.

Now that the Seakale question has cropped up, and as "H." asks, "Can Seakale pots be dispensed with?" I will give two instances where good Seakale has been forced without the aid of pots or boxes. A plan was in operation more than twenty years ago, and was carried out as follows:—

The beds were raised a little above the level of the surrounding ground, and between each bed was a trench about 2 feet deep and 2 feet wide, with, I believe, a single brick wall on each side built pigeon-hole fashion. These trenches were for the fermenting material, which was filled up to the level of the walls, and the crowns were then covered with the common Bracken Fern to the depth of 18 inches. This plan produced some of the best Seakale I have ever seen.

The next plan was on the level ground in quarters, not merely beds, but planted at equal distances; in this case sticks were merely stuck round the crowns, and their tops brought together cone-shaped, then a little long litter placed round the sticks, then the fermenting material. This plan also answered very well. This was in a large forcing establishment. Many people, I believe, force their earliest batches in Mushroom houses, which is a saving of labour, and may be very convenient, and the Kale quickly produced; but still I am no convert to that system. I am of opinion that No. 1 plan is commendable for early forcing. I cannot clearly see that pots or boxes can be dispensed with, even if sticks are used, which seldom last more than one year; and as pots are so liable to be broken, I think boxes are the next best, and perhaps the cheapest in the end.

Having a lot of spare drain tiles of a large size, I place two of these together on their ends; the bottom edges coming together form a sort of oval, the top is covered with a piece of slate. This plan answers very well. I usually place a stick on the top of the fermenting material just over the tiles; this is a guide, and saves that probing process with the fork tines, which in the case of pots is the primary cause of breakages.

Now, No. 1 plan always struck me as a step in the right direction. If the heating material can be more equally divided between root and branch it must be a more natural way of forcing. What could be better than such a plan for Asparagus, the beds of course to be covered with glass? I believe a good deal of the best forced Asparagus is grown in France on a similar principle.

I think that many of us have for a long time been forcing Seakale and Rhubarb at the wrong end. Even if these roots are taken up to be forced there is a great mutilation, which must to some extent weaken the roots, and as a matter of course the forced heads cannot reasonably be expected to be so fine as from the outdoor forcing.—G. R. Allis.

GERANIUMS FOR BEDDING.

I want to induce all to obtain and none to throw away the following:—Gloire de Corbeny, salmon; Lady Kirkland, Bonfire, Warrior, Vesuvius, Lucius, the best bedder ever raised; Claude Lorraine, Maia, Creed's Seedling. *Bronze*—Black Douglas, Emperor of Brazil, Maréchal McMahon, Kentish Hero (for large beds), Sybil, Dwarf. *White-edged*—Beaton's Nosegay, Flower of Spring. *Silver Tricolor*—Mrs. John Clutton, Charming Bride. *Golden Tricolor*—Mrs. Pollock. Edging for Iresine: Crystal Palace Gem.

In leaving out Jean Sisley I do it with regret, but no one will obtain a mass of bloom from her.

A really good white is yet to be found, and Madame Vaucher had better be kept. All your readers are glad to learn the name of any really good plant. We know the best Roses now, would some one have an election of bedding Geraniums? It would save much money and time.—Age.

ROYAL HORTICULTURAL SOCIETY.

Mr. Cutbush has very ably exposed the miserable vacillation of the Royal Horticultural Society's Council and the injury thereby inflicted on those on whom, after all, depends the future of the Society, for I suppose it will be allowed that if there are no exhibitions there will be an end of the Society; and I think we must come to the resolution not to send anything more until the prizes of last year are paid and a schedule worthy of the Society acted upon, for it seems that issuing one and acting on it are two different things at South Kensington. I allude to the prizes of last year, because I hear it is coolly debated whether they shall be paid or not. If there is any hesitation upon the subject it will be the duty of the exhibitors to at once try whether the Council cannot be compelled to pay. There is nothing that I am aware of in their charter to enable them to act dishonestly.

I know that there is one reason that keeps some exhibitors from acting on this suggestion—lest it might appear that they had less confidence in Mr. Barron than in his predecessors; but let it be clearly understood that, on whatever other point the exhibitors may differ from the Council, they are unanimous in their approval of the step which placed the management of their exhibitions in the hands of one so generally liked and so thoroughly competent as he is. In him at any rate they would be sure to find no dilatoriness, want of courtesy, or firmness.—An Exhibitor R.H.S.

I have informed myself of the numerical strength of the several classes or parties, so to speak, who, divided against each other, and, indeed, against themselves, have been and are working out the ruin of that great Society which it was their bounden duty to support. I was happy to find that the number of those who remain attached to a legitimist policy, and ready to support the few leaders of horticulture proper which are left to us, is greater than I expected; indeed, I cannot otherwise account for the singular transaction which occurred with regard to the report at the anniversary meeting when that document was virtually condemned, together with the framers thereof. On that occasion the Council were saved from resignation, not upon the merits of the case, but by the charming manner and high gentlemanly bearing of their chairman. After this occurrence I own to having cherished a shadow in the form of a hope that something of the following kind might have been effected—to wit, that a fusion between the old independent horticultural party and that of the local Fellows might result in the formation of a Council containing a good proportion of the former. That these two parties (in Council) having agreed to act honestly together might have together gone to the Commissioners and so entered into arrangements of such a nature (upon the basis of cancelling the lease) as to leave all parties in the possession of their desired privileges. The thing is, I believe, still possible

in some shape or another. Should anything feasible of this kind turn up, I and my friends will be ready to give it their support. If not, and the Council stick to their policy of making use of these usurper's powers to retain the lease and starve the Society, then I counsel on the part of my brother horticulturists a firm, compact, and persistent opposition to an evil and selfish influence.—R. Trevor Clarke, *Welton Place.*

EARLY WRITERS ON ENGLISH GARDENING.

No. 4.

SIR HUGH PLATT.

An inventor who devotes himself to the completion of some one work which if effected will be of national importance is worthy of admiration—such men were Arkwright perfecter of the spinning jenny, Watts of the steam engine, Wedgewood of porcelain, and Stephenson of the railway system; but a schemer—a man who potters over small things, all insignificant, and flitting from one to others as unimportant, is one who is usually an annoyance and too often a mere waster of his time and money. Such a man was Sir Hugh Platt.

I have vainly sought to discover his parentage and the place and date of his birth, but it is evident that early in life he was in the metropolis, for he tells in one of his prefaces that "he had drawn the longest line of his life within the liats and limits of London."

In the Register of Lincolns Inn is recorded that on the 4th day of May in the thirteenth year of Elizabeth's reign he was admitted a student, introduced by John Pinkerynge and Thomas Lodge. He was therefore entered as a student in 1571. He probably was then about twenty, and if so would be only fifty-seven at the time of his death in 1608. This date last named is certain, for he executed his will on the 19th of October, 1608, and he died between that day and the 1st of November of the same year, on which day the will was proved. He describes himself as of Stepney in the county of Middlesex, knight, and wisely, being a lawyer, made his will very plain and brief. Having previously provided for his sons, he left his wife Judith all his property and sole executrix, relying that she would provide for their daughter of the same christian name, and specifies none of his property except a brewhouse in the City with other houses thereto belonging.

Charles Bellingham, who edited the sixth edition of Sir Hugh's "The Garden of Eden," speaks in its dedication of his "near alliance" to Sir Hugh, and it is not improbable that Bellingham had married the daughter mentioned in his will.

The sons seem to have been well provided for and prospered, for in Hornsey Church is a monument to the memory of William Platt, founder of some fellowships in St. John's College, Cambridge. He died in 1637; and the inscription tells that he was son of Sir Hugh Platt of Kirby Castle, Bethnal Green, which then was included in Stepney parish. That monument, kept in repair by St. John's College, bears testimony to the good position of the Platt family, for on it are blazoned more than thirty coats of arms of families allied to it. The wife of Sir Hugh had pre-deceased that son two years, for in the register of the same church is this entry, "The Honourable Judith Platt, wife of Hugh Platt, Knight, buried Jannary 28th, 1635." The wife of Robert, another of Sir Hugh's sons, was also there buried in 1656. Lysons thinks that it was also Sir Hugh's burial place; but there are no registers of the date when his death occurred.

In 1594 Sir Hugh resided at Bishop's Hall, about a quarter of a mile eastward of Bethnal Green, a residence of Bishop Bonner's, if he was not also its builder. But Sir Hugh at the time of his death resided at Kirby Castle. It was built in Queen Elizabeth's reign (1570) by Thorpe, the architect of Holland House, for John Kirby, a London citizen, and who seems to have suffered from the over-expenditure. He, as well as other sufferers from a similar cause, was satirised in a doggerel rhyme—

> "Kirkeby's Castell and Fisher's Follie,
> Spinila's Pleasure and Megse's Glorie."

Kirby Castle was built on the site previously known as "The Blind Beggar's House." That "beggar," believed to be a son of Simon de Montfort, Earl of Leicester, was left for dead at the Battle of Evesham in Henry III.'s reign; but a baron's daughter searching for her father's body found young de Montfort, married him, and for safety they assumed the character of beggars. Their only child was the "pretty Bessie" of the ballad in the Percy "Reliques."

> "'My father,' shee said, 'is soone to be seene,
> The silly blind beggar of Bednall Green,
> That daylye sits begging for charitie,
> He is the good father of pretty Bessie.'"

In those days no societies existed for the promotion of botany or gardening where those who delighted in their cultivation could associate. The only substitute for such societies was acquiring an intimacy and correspondence with congenial fellow students. This was done by Sir Hugh, who, Bellingham says, had communications with every gardener of any note in England who tested his suggestions, and among them were Hill, Taverner, Pointer, and others who are also mentioned by Gerarde. They deserve a brief memorial here. Sir Hugh directs how Carnations, Gilliflowers, and Pinks may be grafted "upon one root of Carnations;" and he says this was imparted to him by "Mr. Jarret, the chyrurgeon in Holborn." Gerarde also knew him, and describes him as "a curious searcher of simples." Tulips were one of his especial favourites, propagating them by seeds and offsets for twenty years, and every season producing "new plants of sundry colours not seen before, all which to describe particularly were to roll Sisyphus's stone or number the sands." Jarret was also a correspondent of the botanist Clusius, who speaks of him with praise and acknowledgements of the plants received from him.

The authority Sir Hugh most frequently quotes is "T. T.," and this was evidently Thomas Tusser, who was his contemporary, of whom you published my memoir some months since. "Master Hill" was also one of his authorities, and probably the Thomas Hill whose portrait and biography were the first of this series. "Andrew Hill" is a different authority quoted by Sir Hugh. He quotes (Garden of Eden, i., 36) "Gardiner's Kitchen Garden, printed 1599," a book unknown to me.

Although Sir Hugh derived from others most of the garden knowledge he published, yet much of it was from his own experience, and he had more than one garden. He tells of the results of pruning frost-bitten Roses "upon divers standards at Bednal-green," and that by cutting down Beans he had from the same plants a second crop—"This I have proved in my garden in St. Martin's Lane." In the same volume there is the "old, old story," of dishonest seedsmen and poultry dealers, for Sir Hugh indignantly writes, "I would there were some fit punishment devised for these petit coseners, by whose means many poor men in England do oftentimes lose not only the charge of their seed, but the whole use and benefit of their ground after they have bestowed the best part of their wealth upon it. Cheapside is as full of these lying and forswearing huswives as the shambles and Gracechurch Street are of that shameless crew of poulters wives, who both daily and most damnably, yea, upon the Sabbath-day itself, run headlong into wilful perjury almost in every bargain which they make, selling cocks for capons when they have pared their combs and broken off their spurs; old hens for pullets when they have broken their pinions and brestbones."

If space could be allowed much more I should like to quote, but let me conclude with a list of his very varied works, and for the most part published after his decease.

"The Jewel House of Art and Natnre; Experiments in Husbandry, Distillation, Chemistry, &c. 1594. Edited by D. Bryant in 1653."

"H. P. Manuale, &c. 1594." A Selection of Moral Sentences from the Fathers and Patriarchs.

"A Discoverie of certain English Plants. 1595."

"Delights for Ladies to Adorn their Persons, Tables, Closets, with Bouquets, Perfumes, and Waters. 1602." In the Preface he hopes that it will not receive the same unkind acceptation as his first fruits, "The Jewel House of Art and Nature," and his hope was realised, for I know four subsequent editions.

"A New, Cheape, and Delicate fire of Cole-balls. 1603." Is merely recommending coal dust to be made into a paste with loam and formed into balls for fuel.

"Florae's Paradise Beautified with Sundry Sorts of Delicate Fruits and Flowers. 1608." This contains much good gardening information, combined with much mysticism and reliance on planetary influence.

"The New Founde Arte of Setting Corn. 1650." This was a decoy publication. It advocates spade husbandry, and "the new founde arte" probably was dibbling, but it is not revealed, and the reader is informed that of the secret more might be heard by inquiring at the printer's.

"The Garden of Eden or an Accurate Description of all

Flowers and Fruits Growing in England, with Particular Rules How to Advance their Nature and Growth. 1652. Edited by C. Bellingham." The sixth edition is dated 1675. It is only a reprint of "Florae's Paradise." The second part of the "Garden of Eden," all from MSS. left by Sir Hugh, was published in 1659 and 1675.—G.

MR. W. PAUL'S EXHIBITION OF SPRING FLOWERS.

For a few days longer this Exhibition invites inspection at South Kensington, and those amongst flower lovers who have not yet seen it would do well to do so, as it is a display worthy alike of public patronage and of the reputation of the able and spirited proprietor of the Waltham Cross Nurseries. When Mr. Paul exhibits something good is expected, and is invariably provided, and it was the unanimous opinion of the many spectators on Saturday, the first day of the Show, that the collection is fully equal if not superior to those of former years. The plants are arranged in the western arcade and reach nearly its entire length. They comprise Roses, Camellias, Hyacinths, Tulips, Narcissus, and other popular flowering plants, with a background of Palms and foliage plants.

The Camellias are excellently-bloomed plants in the perfection of health, and comprise besides those we have previously noticed, Dante, white; Madame Lebois, fine salmon red; Centifolia Rosea; Jargioni, white; Archduchesse Augusta, crimson, fine deep colour; Perpenti, rose; Pius IX., rose, very free; Lucretia Guzarrini, rose, white-striped, good form and free; Belle Jeanette, red, shell-like petals; Teutonia, var. amabilis, rose and white, attractive; Souvenir d'Emile Defresne, white and red, very striking and free; La Reine, fine white; Valtavaredo, rose, &c. All these are varieties of sterling merit.

The Roses both in plants and cut blooms are an attractive feature and receive a good share of attention. Well-bloomed plants of John Hopper, Céline Forestier, Victor Verdier, Duke of Edinburgh, Princess Mary of Cambridge, and Mdlle. Marie Rady make the principal show; still the smaller plants of the newer varieties possess a magnet-like influence in attracting attention. Of these Richard Wallace is good; St. George is a rich velvety crimson with a good substance of petal; Diana is of the type of Jules Margottin, but richer in colour. It is evidently very free and gives promise of usefulness. Star of Autumn is a flower of fine build and full. It is of the John Hopper type, but deeper in colour than that Rose. Peach Blossom is a new Rose of globular form and delicate colour. Amongst Tea Roses Anna Olivier is a fine light flower with coppery centre and good substance of petal; Catherine Mermet has lovely blooms; President is charming; Souvenir d'un Ami is fine, as are Comte Taverna, Souvenir d'Elise, and others. In boxes of cut blooms which have many admirers, were John Hopper, Prince de Portia, Mdlle. A. de Rougemont, Fisher Holmes, Mdlle. de Stella, Pierre Notting, Paul Verdier, La France, Lord Clyde, Mdlle. Bonnaire, &c. These were excellent for the season, La France being especially admired.

We now turn to the Hyacinths. These are a show in themselves. To this flower Mr. Paul devotes special attention, and has been instrumental in introducing some of the first varieties of the day. The plants are characterised by sturdy vigour rather than mere length of spike—that is, they have breadth as well as length, and, as a rule, the bells are remarkably fine. Of the Reds, Vurbaack is the best, being of high colour with a fine spike; Garibaldi is exceedingly rich, as also is Prince Albert Victor, and Linnæus. Solfaterre, Koh-i-noor, Fabiola, Princess Clothilde, Prince of Orange, Macaulay, Von Schiller, and the old double Waterloo have just claim to honourable mention.

The Blues are well represented by robust spikes of King of the Blues, General Havelock, Mimosa, Baron Von Tuyll, and Haydn (mauve), amongst the darks; the lighter shades having as the best Lothair, very good; Lord Byron, Princess Mary of Cambridge, fine bells; Admiral de Ruyter, silvery bells of good form and substance; Czar Peter; Blondin, extra; La Candolle, Charles Dickens, and Couronne de Celle. The best of the new sorts are Von Moltke, dark blue and white; Baron Beust, light blue and white; and Christy Minstrel, very dark.

Amongst Whites the best are La Grandesse, the first white Hyacinth of the day; L'Innocence, fine; Miss Nightingale, pure; Paix de l'Europe, fine spike; Baronue Van Tuyll; Snowball, massive bells; Mont Blanc, Leviathan, Alba-Maxima, Madame Van der Hoop, and Snowspike (new). This is very pure with beautifully formed bells and a nice spike. It is a very promising variety.

Of the Yellows, Bird of Paradise and L'Or o'Australe are the best, the bells of the latter being as fine as those of the light blues, which is not the case with yellow Hyacinths generally.

Tulips were a very gay bank, and comprised Proserpine, rose purple, fine; Bride of Haarlem, crimson and white; Cardinal Gold, scarlet and gold; Cerise Gris de Lin, chocolate and fawn; Bacchus, red; Belle Alliance, glowing red, dwarf; Rosa Mundi, rose and white; Grootmeester Von Maltha, crimson and white; Standard Royal, fine, white and bright rose; Leonardo da Vinci, glowing scarlet; Lady Palmerston, Brutus, and Standard Golden were very distinct and brightly striped with red and gold; Cottage Maid and Rose Luisante, rose and white; Chrisselora, yellow; and Pax Alba and Pottebakker, white.

The Narcissus are remarkably good, the best being Bathurst, Queen of the Netherlands, Glorious, Florence Nightingale, Bazelman Major, and Sir J. Paxton. These are the best of the fine collection.

The groups enumerated with Primulas, Cinerarias, Deutzias, Spiræas, Cyclamens, Lilies, &c., constitute a display worthy of patronage, and of the gay period of Easter week.

ROYAL BOTANIC SOCIETY.

The lingering winter reaching far into spring has not hitherto brought flower-show weather, but Wednesday the 31st, for the first Regent's Park Show, was mild, yet dull. But the dulness without was atoned for by the brightness within, for the Show was a good one, nearly all the classes being filled with excellent examples of culture. We were obliged to leave before the awards were completed, but a general idea of the Show may be gathered from the following jottings. The plants were arranged in the corridor reaching its entire length, and occupying a portion of the conservatory.

In the class for twelve stove and greenhouse plants (open), Mr. Ward had Anthurium Scherzerianum, with the finest spathes perhaps ever seen; a good Eriostemon, Franciscea, Cytisus, Lycaste Skinneri, with upwards of twenty blooms; a fine Cypripedium villosum, Azaleas, Heaths, &c. Mr. Wheeler had a good group containing a large Chorozema, Pancratium fragrans, Imatophyllum, &c.; the same exhibitor had also a mixed group of plants.

In the class for six greenhouse Azaleas in 12-inch pots (amateurs) Mr. Ward's plants were dense masses of fine blooms. Stella, punctata omnicolor, A. Borzig, Model, Roi des Beauties, and Madame Vander Cruysseu. Nice plants also came from Mr. Wheeler, and a larger half dozen from Mr. Child, gardener, Garbrand Hall.

Six greenhouse Azaleas in 12-inch pots (nurserymen), Messrs. Cutbush & Son had small but well-bloomed plants.

In the class for six Chinese Primulas (open) Mr. James and Mr. Wheeler sent plants which had been finer a fortnight ago than now. They were large, with fine blooms, but were lacking in freshness.

In the class for nine Cinerarias (open) Mr. James had splendid plants of William Reeves, Attraction, Treasure, Right Hon. B. Disraeli, Purple Gem, very fine; Agrippa, Pandora, Floribunda, and Admiration. He also exhibited a group of smaller plants of remarkable substance of bloom and distinct colours.

The Lilies of the Valley were very good, the pots from Mr. James being vigorous in foliage and bloom. Those from Mr. Child being also good; while Mr. Tom's were more floriferous than either, but with smaller flowers.

Hyacinths had a fine cheery effect collectively, both by their numbers and contrasting colours. There were also undoubtedly some fine spikes, but it is not less certain that there were still more that can only be regarded as moderate. In the amateurs' class Mr. Douglas had spikes worthy of himself; and very good plants also could be picked from the collections of Messrs. Potts, Toms, Collins, and Weir. In the nurserymen's class W. Cutbush and Sons were in the ascendent; and Messrs. Carter & Co. and Barr & Sugden staged some charming flowers. In the class for single or compound spikes Messrs. Cutbush, Mr. Douglas, Barr & Sugden, and Mr. Toms competed.

The Tulip classes were, as usual, very gay, and contained some splendid flowers. In the amateurs' class for four varieties Mr. Douglas had massive blooms of Proserpine, Keizer Kroon, Vander Meer, and Pottebakker. Mr. Toms had Fabiola, Rose Luisante, Cerise Gros de Lin, and Pottebakker. Mr. Weir had the same varieties as Mr. Douglas, but substituting Vermillion Brilliant for Keizer Kroon. In the nurserymen's class W. Cutbush & Son had remarkably dwarf-grown pots of the above-named varieties, and Messrs. Carter and Barr & Sugden staged excellent collections.

In the class for six Deutzias Mr. Douglas had snowy columns, with fine blooms and good foliage. Mr. Child had standard plants. Messrs. Carter, Mr. Toms, and Mr. James also entered smaller but well-bloomed specimens.

In the class for twelve Cyclamens a fine effect was produced by the two champions, Mr. Little and Mr. James. Those from Mr. Little were marvels, and those from Mr. James were models of culture. Each exhibitor also staged imposing collections of this attractive flower.

In Clematis Mr. Wheeler was the only exhibitor with nicely-bloomed plants of the best varieties. He had also six forced shrubs, four Rhododendrons, an Azalea, and a Lilac.

Amongst new plants Messrs. Carter had a brightly-marked

Coleus Duke of Edinburgh and a bold-foliaged fimbriated variety, Mandarin; also a hardy purple mauve Primrose, Lady A. Taylour. Mr. Williams had his new Anthericum variegatum, Alsophila Van Geerti, Encholirion corallinum, and the graceful Palm Geonoma gracilis. Mr. Douglas also sent a fine Amaryllis, Sir J. Cathcart. Amongst the "new" plants also was a good specimen of Dendrobium fimbriatum oculatum from Mr. Stevens, gardener to G. Simpson, Esq., Reigate, laden with its bright yellow flowers. Mr. C. Turner, Slough, sent a basket of Double Violets of the Neapolitan type. The plants were sturdy and floriferous. Mr. W. Paul sent a new Rose, Star of Waltham, which is undoubtedly a fine dark Rose; and Mr. Bennett, Manor Farm Nurseries, sent Tea Rose Marie Guillot, but its delicate petals were injured in transit; also a new Hybrid Perpetual Comtesse de Serenyi.

Amongst the miscellaneous groups, which were an effective feature of the Show, were Mr. Williams's stove and greenhouse plants, consisting of a fine specimen of Imatophyllum, a good Franciacea, Aërides Fieldingi, Dendrobium thyrsiflorum, Cymbidium eburneum, Amaryllis Mr. Little, Tillandsia Lindeni, Ferns, &c. A beautiful collection of Roses in pots, also boxes of cut blooms, were sent by Messrs. G. Paul & Son, Cheshunt. The plants were good, and the blooms clean and excellent. La France, Richard Wallace, Paul Verdier, Edward Morren, Duke of Edinburgh, Madame Willermoz, Céline Forestier, a fine group of Cheshunt Hybrid, Madame Lacharme, Captain Christie, and a charming new Tea Rose of a rich salmon colour, Mdlle. Marie Finger, are amongst the most attractive of this creditable contribution. A box of cut blooms of Maréchal Niel from W. J. Woodley, Esq., Oakwood Lodge, were also very attractive.

Mr. C. Turner sent a group of two dozen Ivies in pots, excellently grown plants, and his bank of richly berried Aucubas were very effective.

Mr. W. Paul staged well-bloomed plants of Camellias, and a box of beautiful cut blooms; also a collection of Waltham White Primula with gigantic flowers. Messrs. Carter & Co. staged a collection of fifty Hyacinths with many good spikes and well-finished trusses, a glowing bank of Tulips, and excellent plants of Spiræa japonica. Messrs. Barr & Sugden had similar groups with a showy collection of Narcissus. Thus was composed the first Exhibition at Regent's Park, and which will compare favourably with its predecessors of the same period of the year.

THE MULCHING OF FRUIT TREES.

It is a common and a good practice to cover the surface of the ground in autumn over the roots of newly-planted fruit trees with good manure, both to act as a protective against the weather, and as conveying nourishment to the soil by the rains washing down its virtues.

Now, at this period of the year should that surface-covering remain over the roots, or should it be removed? There is no question as to its benefit during winter, but it is not at all certain that its removal during the spring is an advantage or not. Probably nine persons out of ten would say, "Oh! leave it on, of course."

Now, in ordinary free-growing trees, as Apples, &c., the point is not of great moment; but in the case of trees planted on a south wall, Peaches, Nectarines, &c., it is absolutely necessary that the best possible practice be adopted to induce their free growth. The first condition to secure to that end is root-action as early in the spring as possible to continue the supply of sap after that stored up in the branches has been appropriated by the bursting buds. For this there must be earth heat, as, until a certain degree is reached, the roots will not move at all.

Now is it not reasonable to suppose that this necessary earth heat is imparted by the sun sooner and quicker when the surface is exposed than when it is covered? The difference in heat of the surface of a south border between (in April and May) being covered and uncovered is very great.

Last year out of six newly-planted Peach trees the surface-mulching was drawn off five of them every morning, and pushed on again at night. It was only the work of five minutes a-day. The five trees flourished admirably, but after the first break of the buds the growth of the covered tree was stubborn, it became infested with insects, and it never did any good. This is a simple but important subject for abler men than—A Young Gardener.

NOVELTIES IN THE ROYAL GARDENS, KEW.

In the house No. 1 must be mentioned Phrynium sanguineum, chiefly beautiful from the scarlet bracts subtending the branches of the panicle. The colour is similar to that of Rhubarb leafstalks when in the most brilliant condition. In contrast to these the flowers are white, and the entire inflorescence would be most attractive in the choicest bouquet. Novelty is ever desired, and this could be used with good effect from its singular form as well as for its colour. It lasts in perfection a considerable time. In gardens it was first called Maranta sanguinea, and the well-known cultivation for that genus is the best for this. Out of flower it is ornamental, not only from its peculiar habit of producing tufts of foliage on long leafless stems, but from the purple under-surface of the Maranta-like leaves. It was figured in the "Botanical Magazine" of 1852; a volume, we may remark, which contains many plants of special interest introduced about that time, and now established in our gardens—Jasminum nudiflorum, Lilium giganteum, Calanthe vestita, Paulownia imperialis, Nymphæa gigantea, N. Devoniensis, Rubus biflorus (R. leucodermis), and several others. The blue Meconopsis Wallichi is there also, it has recently been re-introduced after being lost for many years.

In the Conservatory we observe Podalyria calyptrata, an old plant seldom seen, though very ornamental from its profusion of pink and white Pea-like flowers. It is easily grown, and flourishes well in soil consisting of rather more than half peat, and may be increased from seeds or cuttings. Orobus vernus is here very attractive, and is well worth forcing for its flowers of purple turning with age to a kind of steel blue. The foliage is very pretty, and of a lovely green.

Some pots of Lachenalia tricolor var. lutea are very ornamental in the Cape house. This genus has been sadly neglected, though, perhaps, not more so than bulbous plants in general. Interest in this class is certainly reviving, and is taking the special attention of several cultivators. The cultivation of the above is very easy, and by a little management may be had in succession for a considerable time. They are grown best in rich sandy loam, and requiring a season of rest, must always have water according to their condition. On the same shelf is a plant of Scilla peruviana var. glabra. The colour of the flower is very good, almost like S. siberica. It differs from S. peruviana by the leaves not having a ciliated margin, though quite distinct from the common glabrous variety Ughi.

Gardenia Stanleyana rarely exhibits flowers; recently, however, it has been conspicuous in the stove with a number of its extraordinary trumpet-shaped blossoms, altogether unlike its well-known congeners. The corolla is about 9 inches long, the slender tube expands into a bell-shaped mouth, with a spreading limb of five ovate segments, about 4 inches across from tip to tip. Its colour is white, spotted with purple, and a band of the same colour runs down one side of each lobe. To cause it to flower we advise that plants be at once potted, using a mixture of rather more than half peat with fibrous loam, the whole enriched with dung; then plunge in bottom heat of about 85° during the time of growth, after the completion of which remove from the bed, and during winter give as little water as necessary. If the plant intends to flower, buds will form about the early part of next year, and may be perfected about this time. Rich feeding seems important in the cultivation of Gardenias.

OUR BORDER FLOWERS—BARRENWORTS.

Much might be said respecting this charming group of spring and early summer flowering plants. A collection—or may I say a selection?—needs only to be seen to be appreciated. Had they been an expensive and difficult tribe to cultivate perhaps they would have attracted more attention. I regard them as among the neglected occupants of our rockeries and herbaceous borders. In many places you look for them in vain; you may go from place to place and peer into every nook, but you see no plant of Epimedium. Why is this? Is it because they are unknown, or that they are beneath the cultivator's notice? If we want to see those gems of spring we must look for them where herbaceous plants are cared for and are carefully tended. With this as other plants, it is not enough to just thrust them into the ground and leave them to chance.

We have one at least that is called native by us—Epimedium alpinum, but it has not been my good fortune to the present time to stumble on it at home. I have found these plants of great service in the spring time as pot plants in the spring garden, and in the borders they are not difficult to manage, and when once well established they last a long time,

and will bear a considerable amount of hardship. Generally speaking they are a moisture-loving race, but should on no account be exposed to stagnant water. They are very useful where cut flowers are in request, their lovely flowers and beautiful foliage commending them for all purposes that flowers can be put to. I find that good drainage, a moderately moist exposed situation on rockery or border, a compost of good loam, sandy peat in equal proportions, a little leaf mould, with a little coarse sand and grit is essential to their well-doing. They require a depth of 18 or 20 inches of soil to develope their character.

If required for pot culture they can be kept plunged in any out-of-the-way corner when they have matured their growth; but they should be attended to with water when they require it. Epimedium rubrum is to my mind one of the foremost of the train, it is of free growth when well established, and in bloom it has a grand appearance; E. sulphurea is a very desirable plant, especially on the rockery; E. pinnatum elegans affords a fine contrast, and is one of the best of the family; E. macranthum is a very desirable plant, and when well established presents a pleasing feature on the rockery or in the border; E. grandiflora should be in all herbaceous borders. This variety affords a grand contrast in colour among the red and yellow kinds; being white makes it still more desirable. E. alpinum should have a moist situation at the foot of the rockery. It will also do well in a moist peat bed.

Fig. 60.—Epimedium alpinum.

The Epimediums are a widely distributed but interesting family, increased chiefly by division after they have made their growth. I have not been able to secure seed from any of the kinds. The early blooming varieties are well adapted for the spring garden, grown in pots and plunged where they are required, to be removed when the bloom is passed. Sometimes they suffer from frost in the spring. I find that a good-sized pot inverted over them is a sufficient protection.—Veritas.

THE VICTORIA AND PARADISE NURSERY, UPPER HOLLOWAY.

Mr. B. S. Williams' establishment is known as amongst the first of its kind in this country. Its prominent standing has been secured by the thorough knowledge of its proprietor in practical plant-culture, and the enterprise he has brought to bear in commercial horticulture. His policy has not been to bury himself in his nursery and, hermit like, to shut himself out from the world, but he has by every legitimate means sought not only to make the charms of plants known, but has taught how they may be successfully grown. He has by this means achieved honourable fame, and has established a name which is familiar in home and continental garden literature.

There are establishments where the glass structures are more numerous than are to be found in this nursery, but very few where they are larger and better adapted for their purpose, and fewer still which contain better examples of skill in plant-growing and superior choice specimens.

In Palms and tree Ferns the nursery is especially rich, such, indeed, as we have not seen in any corresponding establishment in Britain, and only in one or two of the great continental plant emporiums.

In the hardwooded department the Azaleas are superior specimens of health combined with size. When in bloom, or out of bloom, these splendid plants are worth going a long journey to see, so remarkable are they for their general excellence.

The Camellias are also in exceedingly good order; indeed, no collection could be more thoroughly healthy and clean. Their first blush of beauty is over, yet fine blooms of the following good varieties are still more or less plentifully distributed over the plants:—Etoile Polaris, small red; Lemichezi, fine rich pink; Comtesse Eostans, pink and white mottled, good; Henri Favre, fine rosy salmon; Il Cygno, white; Jubilee, white marbled, very fine plant; Montironi Rosea, fine; Madonna, blush; Resplendens, Imbricata, Archduchesse Marie, Duc de Bretagne, Wilderi, &c.

The collection of Heaths is extensive, and the plants are in thorough good trim. It is not often that such plants of the good old Erica. Cavendishi are to be found now-a-days with health and size going so well together. There is an enormous plant of E. depressa—not, however, to be there much longer—said to be nearly a hundred years old, yet as healthy and vigorous as a young plant. It is not necessary, however, to enumerate, as all the best varieties are here in all sizes that can be wished for and vigorous.

The Orchids here are represented by a collection of plants which, as might be expected, are unsurpassable in quality, and embraces the choicest varieties, as well as the more popular kinds which are commonly grown in quantity. Ada aurantiaca is in bloom, and the high-coloured flowers are very telling. Aërides Schrœderi is noticeable, and a splendid plant of A. Fieldingi throwing-up several spikes is prospectively grand. A. Veitchianum is also attractive. Cymbidium eburneum displays its wax-like flowers; and Lælia Turneri is exceedingly rich. The Cypripediums contain beautiful plants of which C. Lowii, C. villosum, C. barbatum, and C. Roezli are flowering. Dendrobiums in bloom are represented by D. infundibulum, D. macrophyllum, the lovely D. lituiflorum, and D. Wardiannm. Masdevallia Lindeni is strikingly effective, its rich and distinct colour rendering it very conspicuous. Amongst the Odontoglossums in bloom are O. cordatum, O. luteo-purpureum, O. Uro-Skinneri (fine spike). Amongst Oncidiums are the almost ever-blooming O. cucullatum, and the pretty little O. anomalum. Phalænopsis Schilleriana is charming as usual, and Zygopetalum crinitum and Saccolabium præmorsum giganteum arrest attention. Calanthe Turneri has nice spikes of flowers, and ought to be more generally cultivated, as it is alike beautiful for cutting and for mixing with Ferns and fine-foliaged plants. The stock of Calanthes is very extensive, especially C. Veitchii; this and C. vestita luteo-oculata are two of the best varieties. They are now just showing signs of growth, and are being potted for next winter's blooming. These plants should be grown by all who have the means to grow them.

Palms and Cycads are a great feature in the establishment. A fine stock of that most elegant of all Palms Cocos Weddelliana is kept in a small state for table decorative purposes, and a number of plants of Geonoma gracilis are but little less elegant. Kentias, Verschaffeltias, and Martinezias are well represented in various stages of growth. Fine plants of Dioon edule and Phœnicophorium sechellarum are prominent, and there are striking examples of Cycas circinalis, Encephalartos Lehmanni and E. villosa.

Ferns are also grown largely in this nursery. The Filmy Ferns are in beautiful order. The Todeas, especially T. superba, are very fine, and Trichomanes, Hymenophyllums, &c., are growing luxuriantly. We noticed some very fine plants of Gleichenias, especially G. Mendeli and G. semivestita. A new greenhouse Fern Polystichum Lepidocalon is being raised in quantity in anticipation of a brisk demand.

Amongst the Tree Ferns are some extraordinary specimens high enough almost for a chief to ride under on his elephant, and sufficiently spreading to afford shelter on a grand palaver day to a retinue of dusky followers. The most striking are Alsophila Leichardtiana and the handsome Cyatheas—C. Burkei and C. Dregei. We noticed amongst these the very distinct Lomaria cycadoides.

We expected to find here a fine stock of the new Maidenhair Adiantum gracillimum, and we found it. This might well be styled the Gauze Fern, so exceedingly delicate is its structure, and so clearly can a bouquet of flowers be seen through its network of fronds. The popular A. Farleyense was "becoming scarce" in the Nursery, so said the guide; but he did not define what he means by plenty; his "scarce," however, is half a houseful of plants in all sizes.

In passing through the stoves we found a grand plant

of Anthurium Scherzerianum, and a host of the same valuable variety in small young stock. The newer white form of this is also opening its spathes, which bid fair to be larger in size than previously. Tillandsia Lindeni major is extremely beautiful, and the stock of this lovely flower is being increased rapidly. Abutilon Selowianum marmoratum is very fine, and Ficus Parcelli is particularly clear in its markings. Pandanuses are numerous and in first-rate form, and Dracænas are represented in splendid condition and in fine variety. Phyllotænium Lindeni is very attractive, and a nice stock is being raised of Anthericum variegatum. This is a new plant not yet, we believe, sent out, and is admirably adapted for table decorative purposes. It is a Pandanus-like plant, yet with soft gracefully-arched green foliage clearly striped with white. It is evidently of quick and easy growth, and is likely to become popular. Amongst the collection we noted a good stock of Sarracenias, and the best of the Platyceriums were growing freely.

But we must stop to conclude somewhere, and it may well be in the house first entered—the entrance conservatory.

Here the towering Ferns, the arched Palms, the rigid Aloes, and the stately Dracænas combine to each set off the charms of the other. The Cyatheas dealbata, Cunninghami, princeps, and Smithii are splendid specimens, with fine trunks and expansive heads, and the Dicksonias are equally large. A fine plant of the good greenhouse Palm, Sabal umbraculifera, is noticeable, and there is a good specimen of the hardy Palm Chamærops Fortunei. Dracæna lineata and Cordyline indivisa are worth attention, and a grand plant of Imatophyllum miniatum is throwing up its gay flowers.

In the packing-shed are immense Aloes and fine standard Bays in tubs for outdoor decoration in summer. Packing of plants was being proceeded with for exportation, something like twenty thousand being in course of transit from the nursery. Mr. Burton continues to superintend with his proved ability and uniform courtesy to all.

WHITE AND CLUSTER ROSES.

As the shows for the coming summer are now being arranged, I would, with all diffidence, put in a plea for white and cluster Roses.

It is very seldom one can find the former well represented at shows, owing, I presume, to exhibitors not caring to cripple their stands with the smaller blooms of the white kinds.

In schedules, for instance, where they have usually a class for twenty-four blooms of any one kind, might not that with advantage be substituted by one for the best twelve, or any other number of white Roses in distinct varieties? I think if such a class were introduced wherever possible it would prove an attraction, and also encourage what might well be fostered —the improvement of our white Roses.

Cluster Roses, again. Cannot something be done that Rose-lovers may see them at the shows? Many kinds are little known to most people; they are very lovely, and if exhibited in full cluster, would agreeably relieve the somewhat flat sameness of the present orthodox mode of showing separate blooms. —Cornubia.

P.S.—In my notes published on page 230, "Perfection de Lyon" should be "Perle de Lyon."

FLOWER MISSION AMONG THE SICK-POOR IN EAST LONDON.

Depôts are now opened at the Home of Industry, Commercial Street, Spitalfields, E., and Conference Hall, Mildmay Park, N., for the supply of the hospitals and missions nearest them. Flowers and fruits of all kinds would be most thankfully welcomed if sent addressed to the Secretary of the Flower Mission at either of the above depôts before 11 A.M. on Tuesday and Thursday mornings throughout the season.

The following extract from a letter of thanks for flowers will show how greatly they are needed and appreciated:—

"*From the Discharged Female Prisoners' Aid Society.*
"*Nine Elms House, Vauxhall.*

"When the Daffodils arrived they really made quite a sensation in the wash-house, that a kind lady thought of them in the Isle of Wight! Then the beauty of the flowers! Every woman and girl got a bunch. We have about twenty-six girls in our school here, and they were so pleased to have them to lend for the Sunday evening mission service, to put on the table to show to and please our other congregation of waifs that comes in then. It was really very touching; and a week later when I was at the class the remains of some were carefully treasured and put before me. So think of us occasionally again. I visit in the cancer ward at the —— Hospital occasionally. What a boon your flowers would be there! At present they have a few artificial ones—very pretty to look at—on the table, but that is all. The air of the ward would be all the better for them, for though the ward is very clean and neat, the disease necessarily causes malaria."

THE NEW HORTICULTURAL CLUB.

As Secretary of the new Club I write to state that the difficulties which existed as to obtaining suitable accommodation have been, I hope, removed, and that our Committee have every prospect of, within the next fortnight, concluding an arrangement for a place in every way desirable, situated within three minutes' walk of Charing Cross, and overlooking the Thames Embankment. It will comprise reading room, drawing, dining, smoking and billiard rooms, and all the adjuncts of a west-end club, and on terms exceedingly favourable, involving no risk or responsibility. It is earnestly hoped that it will afford a *point d'appui* for all who are interested in the pursuit we love so well. It will, we trust, be especially valuable to our country members, for whose accommodation a number of bedrooms will be provided. The subscription will be two guineas, with two guineas entrance fee.—H. Honeywood Dombrain, *Sec.*

THE BANANA.

There are several varieties of this fruit cultivated in the Island of Jamaica. Of these the Martinique, as named there, but called here the Jamaica, is considered the best, as being hardier in growth, easier to cultivate, not easily blown or broken down, and the nicest for eating. They bear in one year after planting. The bunches are very large. We have seen some that a man could not lift. The fruit is long, and is of a rich yellow colour. They are often brought here from Nassau. Once planted they require no care, but will continue growing, suckering-out, and bearing in the high woods. They will grow in any soil, but prefer gullies or damp places close to a river or spring. All other sorts of Bananas have been cast aside since these were introduced into the island.

Another long Banana called the Tiger, from the skin of the fruit being striped with black, is grown in some places, but the fruit is not considered so good.

The Otaheite is another of the same class of the long Bananas. The fruit must be very ripe before fit to eat. The flesh is of a rich strawberry colour. They are seldom grown, as they root-up very easily and cannot bear the weight of the bunch. They are not a profitable kind to grow.

Of short Bananas, first is the Dwarf or Chinese, not growing more than 4 or 5 feet high, with a strong stout body. They bear large bunches of fruit hanging nearly to the ground, and stand firm, but the fruit is of no account, and is usually used as a vegetable, the same as a Plantain.

Second, the Redskin. This is a strong-growing plant, bearing large bunches of handsome-looking fruit, and is most saleable in this country, but not considered equal to the Martinique in Jamaica.

Third, the Apple. This is not a profitable Banana to grow. The bunches are medium size, and the fruit about the length of a person's finger and very delicious, but the stalks root-up easily, and they require more cultivating.

Fourth, the triangular Banana, usually grown here, is the meanest of all the Bananas. The bunches are of medium size, but the fruit is not a nice one, being too slimy. They should be baked before eating.

There are some other varieties grown, but those we have mentioned are the only kinds that are commonly met with in the West Indies.

Every negro hut has Bananas growing around it. They are manured with ashes from the kitchen. As the bunches are fit they are cut off and taken into the house to ripen, for Bananas that ripen on the stalks are not near so nice, as they contain a strong alkaline juice, which exudes from the stalk when cut off. The fruit should be allowed to fill out and be fully grown; the bunch is then cut off and hung upside down to ripen in the house. The green fruit can be used as a vegetable by peeling off the skin, washed and boiled, and mashed up with butter and lard, and pepper sprinkled over it. A favourite way in the West Indies is to boil them with salt beef or pork,

and mashed up with some of the fat skimmed off the water. When ripe the fruit can be made into pies, same as Apple pies, or a pudding, by peeling them; then place in a dish and pour butter and sugar that has been rubbed together over them, and bake. They are very delicious done in this manner. Many inquiries have been made to us about protecting the plants from frost. We do not think that any Bananas will stand the frost and cold; the leaves are so thin that they are susceptible to any extreme, but some of the species may do better than others here. In the West Indies when the stalk comes up spindling and weak it is cut off just below the leaves; this does not kill it, but has a beneficial effect in making it thicken out and become stronger. We think that if this plan was adopted with those that had been affected by frost it might have the same tendency; but it should not be done until the cold weather has entirely passed away and the plants show an inclination to grow. As the bunches are cut the stalk should be cut down to within a foot of the ground, cut into pieces and placed around the roots; the same with the leaves. This is returning to the land a part of what has been taken away. The juice of the stalk is good for clarifying sugar. The young leaves of the spire are used for dressing blisters; very cooling and soothing when placed on after the blister is clipped.

We would not advise flooding the roots in the winter, for the frost is seldom severe enough to injure them; it is the leaf that suffers. When plants with young fruit are caught by the frost before coming to perfection we think it is the best plan to cut down the whole stalk at once and chop it up, covering the roots with it. This will enable the plants that are standing to receive the full nourishment on return of spring, instead of wasting its strength on a part that will never come to any good. In the West Indies if the Banana plant is highly manured, the stalk, or body as it is called there, will grow very large and succulent, but at the expense of the fruit, the bunches being small. Ashes have been found to be the best manure that can be given, with an occasional sprinkling of salt.—(*California Horticulturist.*)

NOTES AND GLEANINGS.

Mr. W. A. Lindsay, Secretary of the Royal Horticultural Society, has represented to the Governor of the Fiji Islands the desirability of obtaining their Plants new to horticulturists. The Governor, Sir A H. Gordon, has courteously responded to the representation.

—— We find the following paragraph in the *Bruce Herald* (New Zealand) of January 5th:—"A new species of a vegetable-devouring pest has lately been observed in Napier for the first time. It is a very small black-red insect, like a beetle, and can be seen on the hills in swarms. Through whatever paddock or garden these insects travel they leave nothing green behind them. From the country, also, we learn that grasshoppers are in myriads."

—— A scheme, we understand, is in contemplation for the formation of Manley Hall, Manchester, with its conservatories and grounds, into a Winter Garden, on a scale of magnitude and completeness hitherto unattempted in this country. Manley Hall and grounds comprise an area of eighty acres.

—— The Linnean Society, like many another great institution, had its origin in an accident. The late Sir John E. Smith, then a medical student, was breakfasting one day with Sir Joseph Banks, when the latter told him that he just had an offer of the memoranda and botanical collections of the great Linnæus for £1000, but that he had declined to buy them. Young Smith, whose zeal for botany was great, begged his father to advance to him the money, and at length persuaded him to do so, though not without difficulty. It may appear strange that Sweden should consent to part with the treasures of her far-famed naturalist; and indeed the king, Gustavus III., who had been absent in France, was much displeased on his return at hearing that a vessel had just sailed for England with these collections. He immediately dispatched a vessel to the Sound to intercept it, but was too late. The herbarium books, MSS., &c., arrived safely in London in 1784, packed in twenty-six cases, and cost the purchaser £1088 5*s*. In the following year Smith was elected a Fellow of the Royal Society, and devoted himself more to botanical studies than to his profession as a physician. In 1792 he had the honour of being engaged to teach botany to Queen Charlotte and the princesses, and he was knighted by the Prince Regent in 1814. At his death in 1828 the celebrated collection, with Sir J. E. Smith's additions, was purchased by the Linnean Society.—(*Cassell's Old and New London.*)

—— On the 23rd ult. the freehold estate well known as Meredith's Vineyard was offered for sale by public auction by Messrs. Protheroe & Morris, auctioneers, London. The estate comprises upwards of six acres of land applicable to Vine-growing, or for the purposes of building land. There was a fair attendance, and amongst those present were several of the leading horticulturists and florists connected with the district, and others from a distance. In opening the sale the auctioneer stated that he had gone carefully over the estate and made an estimate of its value as a going concern, which he considered should be about £21,000. He then went into particulars as regarded the breaking-up of the estate, and stated that the freehold land might be put down at £6500; 50,000 feet of glass at £3125; dwelling house, £1400; three miles of hot-water pipes, £792; boilers, £100; brickwork, &c., £300; stonework, sheds, tables, &c., £250; making a total of £12,500. The bidding then proceeded, the first offer being £7500. This amount was increased by £50 upon each offer up to £8650, when the bidding rose to £9000. The advances then proceeded by gradations of £50 until the amount reached £10,000, at which sum the estate was knocked down to Mr. John Cowan of London. The Cowan Patents Company, propose not only to make use of the property as an exhibition of their patent apparatus, where it can be seen in full working order, but will use their best endeavours to maintain its well-earned fame, and, if possible, increase its reputation. It was stated by the auctioneer that there were certain plants, &c., which, in accordance with the conditions of sale, did not go with the estate; and if not taken by the purchaser at a valuation they would be sold by auction at a future day.

INCREASED POWER IN PLANTS TO RESIST COLD.

At a meeting on February 9th Mr. Thomas Meehan referred to a tuber of Solanum Fendleri, exhibited by him some months ago, and which had taken a departure towards those of the common Potato. He had offered some suggestions in relation to the possibility of a common origin of these two species, but among the improbabilities he had classed the power of resisting cold, as, while the common Potato was easily destroyed by frost, Fendler's Potato endured without injury a temperature of zero. He had been under the impression that whatever changes plants might experience in the course of ages, the adaptation to special temperatures was nearly if not quite unchangeable. A recent experience, however, suggested the possibility of more change than he had supposed. During the very low temperature, with the high wind, of a week ago, the frost to the extent of 2° or so, and for a short time, got into a greenhouse with blooming plants, some of which were injured by it. Among these were Calla æthiopica, Browallia elata, Bouvardias, Begonias, and some others. The light frost, in the case of all but the first-named, destroyed the leaves, but left the flowers uninjured. The flowers in their several parts are but metamorphosed leaves, and thus we see that with the morphological advance of the leaf to a petal came an increased physiological power to resist cold. In the case of the Calla the flowers as well as the leaves were destroyed, illustrating the same law, as the spathe of this flower is but a leaf very slightly differentiated, and consequently more subject to the laws regulating leaf life. There was nothing quite new in these observations, as all must remember that when the first light frost killed the Dahlias, Chrysanthemums, and other tender plants, the petals would often remain uninjured after the leaves had been blackened by frost; and also the fact that when the leaves of plants become still more highly metamorphosed and become seeds, those of the tenderest plants would often endure considerable cold. Thus the seeds of the common Convolvulus or Morning Glory, and of the Balsam, or Lady's Slipper, as it is called in American gardens, would live out in the earth with us and grow in the spring, though the plants would be killed by a single degree of frost.—(*American Monthly.*)

Auriculas Growing Tall.—I know Mr. Tymons to be a thoroughly practical and enthusiastic Auricula grower, but I must only repeat that if the stem is cut off where there are no rootlets I do not see the least chance of its rooting. I have never—(but then it may be my bungling)—been able to root

even an offset which had not a tiny root attached to it. It may be very small, but that is sufficient; but if it have none it has ever been with me an ineffectual attempt.—D., *Deal.*

PASSIFLORA EDULIS.

This is an interesting species of an extensive and beautiful family of climbing plants. Most of them require a stove temperature to bring them to perfection, although P. cærulea and its varieties will flourish on a south wall in the open air in the southern counties. But P. edulis while being a native of India will still succeed in a lower temperature than many of its allies—that is, it will cover a roof and flower freely in a warm conservatory, yet to perfect its fruit it requires, and is worthy of, stove temperature. Its flowers are not nearly so beautiful

Fig. 61.—Passiflora edulis.

as those of some other varieties, but its handsome plum-like fruit, which are so easily and freely produced, add an interest to the plant to which its more gay compeers can have no claim. The fruit, besides being decidedly ornamental, has a flavour which is particularly agreeable to some palates; and where such is the case, and means are provided, it is specially grown for dessert purposes. In the gardens of Drumlanrig Castle a house is solely devoted to the culture of this fruit, and large crops are produced. The fruit has a pleasant aroma, is cooling, and has a refreshing subacid taste, and is particularly adapted for allaying thirst in the tropical countries to which it is indigenous.

As an ornamental roof-covering plant it is to be feared that P. edulis has frequently given place to less worthy objects. It is not easy to find a plant more beautiful than this with its elegant pendant shoots laden with flowers and fruit, which hang with an airy gracefulness from the roof of a suitable glass structure; the plant is, moreover, of very easy culture. It should be raised from cuttings in preference to seed. Seedling plants grow freely enough, and soon cover a large space, but they are sparse in blooming compared with plants which have been struck from cuttings. Short-jointed young shoots strike quite easily any time during the summer if put in sand under a bell glass, and attended to by the requisite amount of heat, shade, and moisture.

A suitable compost for established plants is turfy loam two-thirds, the remainder leaf mould, peat, and old decayed cow dung, this to be liberally mixed with sand and broken charcoal. Although the plants require an abundant supply of water during the summer season, any approach to stagnancy is pernicious, and consequently the drainage must be very complete. It is well, too, in potting to place some crocks or rubble round the neck of the plant, as it is apt to canker and decay at the surface of the soil; but to grow it well it should be planted out. Corners of bark pits, walled-off from the bottom, form fitting receptacles in which to plant. In these, with due attention, plants will flourish for many years. In the summer season a free use of the syringe is necessary, as a dry atmosphere, and especially if dry at the root, if only occasionally, at the same time, will certainly invite a crop of red spider. Syringing must be less frequent pending the setting of the fruit, which is aided by each bloom being artificially fertilised with its own pollen. On this point the same treatment that is given to Vines is applicable.

In the winter the roots must be kept somewhat dry, yet even then the soil must always be perceptibly moist. A minimum winter temperature of 45° is safe, and a plant has been preserved for some years at a lower temperature than this, but it is not advisable.

In training, a vital point is to guard against overcrowding. If the young shoots are suffered to cling together and become interlaced, the plant will lose vigour and only produce useless spray. The aim should be to have the young growth thinly disposed, so that each shoot can have the benefit of light and air and become matured. It is only by this means that fruit can be expected. Spring is the best time for pruning, just when the plant is commencing to grow. The shoots can then be thinned-out and shortened, so as to cover the space required. Taking out old wood by degrees and laying-in young is the necessary mode of prolonging the vigour of the plant, and to preserve it in a flowering and fruiting state for many years.

Besides P. edulis, the fruit of P. quadrangularia is eatable. This variety perfects a larger fruit, and has a more beautiful flower than the foregoing. It is also more robust in habit and requires a higher temperature. It is one of the most handsome of the entire genus, and is worthy of being cultivated where a suitable position is at command. The following is Lady Dorothy Nevill's receipt for the preparation of Passiflora jelly:—

Peel and cut the fruit before it becomes over-ripe, cover with spring water and allow the fruit to boil till quite tender. Then strain through a jelly-bag, measure the juice, and to one pint of juice put half a pound of loaf sugar, the rind of four Lemons and the juice of six, then boil very quickly till stiff enough to turn out of the mould. A pot of this jelly made from P. quadrangularis was some years ago submitted to the Fruit Committee of the Royal Horticultural Society and was highly approved of.

HARLAXTON.

Harlaxton is situated about three miles from Grantham, and its manor house may unquestionably be classed amongst the finest of English mansions. Its erection may be regarded as the life-work of the late Gregory Williams Gregory, Esq., who died in 1854, just as his great work was completed. For a period of twenty years £10,000 to £15,000 annually were expended on the fabric and its surroundings, and in order to secure perfectness of detail Mr. Gregory made periodical visits to the Continent to note and subsequently carry into execution the most elaborate examples of architectural ornamentation he could find, and which he could adapt to his magnificent mansion, for that is a term that may justly be applied to this sumptuous pile. Its interior arrangements had the same lavish care bestowed on them, and everything that could be collected in rich and rare furniture and works of art was arranged with consummate taste.

On its completion Harlaxton was regarded as one of the wonders of the time, and an hotel had to be erected for the accommodation of the numerous visitors who came from all parts to see it. Its tapestries were rich, its furniture superb, and statuary inside and in the grounds extensive and costly. So great was its fame that Her Majesty honoured it with a visit of inspection, and there was a general feeling of surmise that it was destined for a Royal residence. This was not to be; but instead, its riches were to be scattered, as the then owner had strangely devised the furniture and works of art to

one, and the mansion and estates to another. The phrase attributed to Marshal Blucher in reference to London, "What a place to sack!" might at that time be applicable to Harlaxton. It became a matter of contention as to what was legitimately to be considered as furniture, and expensive litigation was the result. In the end, however, its treasures were removed, but the present owner, Mrs. Gregory, has laboured to restore, refurnish, and redecorate; and Harlaxton, if a kingly mansion once, is a princely residence now. But the statuary of the grounds cannot be replaced, and only a fine marble bust of Mr. Gregory remains in the gardens.

The conservatory adjoining the mansion is an elaborately finished structure, the stone dressings being especially ornate, and full of costly and superior workmanship. The edifice is in five compartments, the interior dressings being of marble. It is heated so that some portions are devoted to tropical plants planted out and some as cool conservatories. It is filled with good plants in an excellent state of health, and by Mr. Vinden's care is alike interesting and attractive.

The mansion being erected on the side of a steep declivity, and well backed by woods, afforded a fine scope for landscape treatment, and full justice has been done in making the grounds ornamental. They are laid out in broad bold terraces and massive Yew hedge boundaries rising, as it were, mountain-like tier beyond tier, and are reached by broad walks and fine flights of steps. Now we are on a level with rich flower beds and looking down on highly-coloured panels spread out several feet below. The several stone staircases, as they may be called, and balustrades which abound in the grounds are a study for the architect. They are extraordinarily massive, yet exhibit a delicacy of treatment such as can only be seen in miniature in fine art exhibitions.

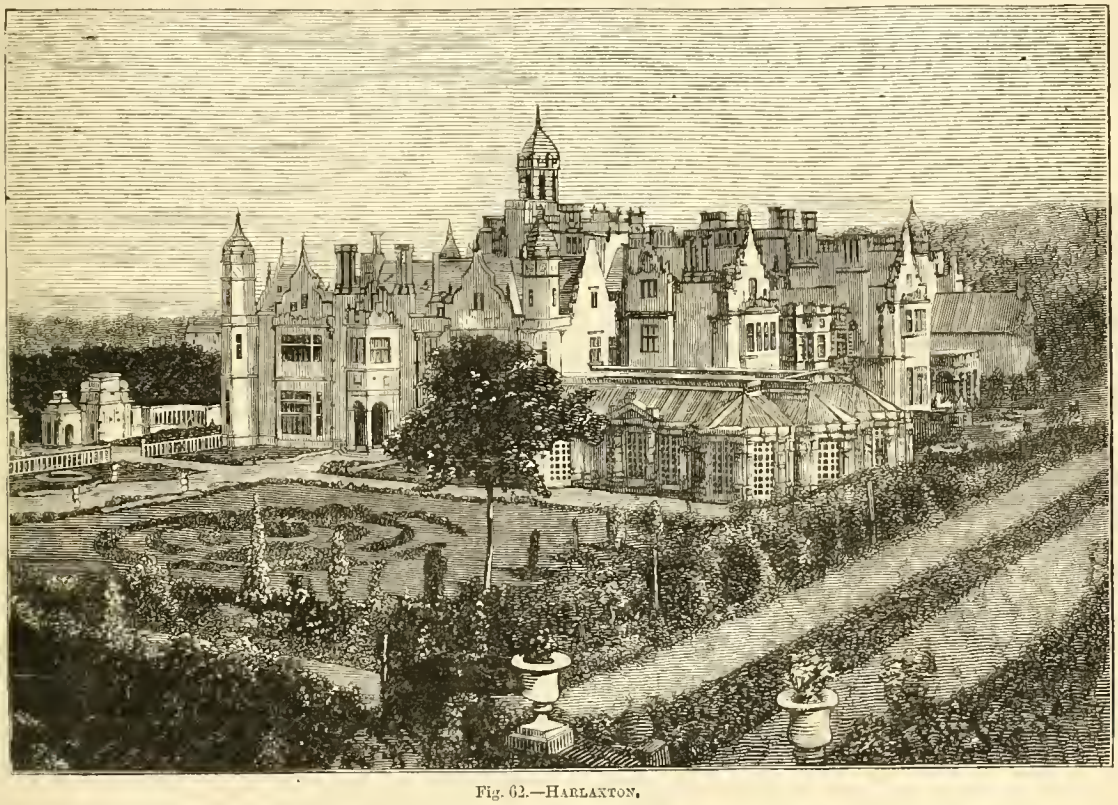

Fig. 62.—Harlaxton.

The Yew hedges mentioned are a fine feature of the place, and so are the isolated pillars of this evergreen, which are interspersed with vases in different parts of the grounds. As a groundwork Berberis (Mahonia) is extensively used, out of which columns of Irish Yews tower sombre and stately, yet toned by the associated stonework.

The flower beds are skilfully managed, and last year, although in one of the driest spots of Britain, they were filled with the best varieties of bedding plants, and (it could only be by unremitting care and labour) presented a mass of beauty quite worthy of this establishment.

The view from the terraces is exceedingly fine, being an almost unbroken panorama of trees, out of which the spires of distant village churches emerge, and bounded by the sweeping woods of Denton and Belvoir.

The kitchen gardens are about half a mile from the mansion, and are unlike any others to be found in Britain. The walls alone cost £10,000, and are extraordinary examples of masonry. They are built of brick with very substantial copings and elaborate stone dressings, and have niches at intervals which had been intended for statuary. The walks are paved with bricks, and are flanked by flower borders bordered by marginal lines of the beautiful blue Gentian. The main walks converge to the point of entrance, and the visitor is almost startled by the extreme novelty of this garden, its walks and walls, when taking his first view. That the effect may be seen in the drive-past on the main carriage way iron latticework openings are made in the boundary wall, and none can pass without an admiring glance.

The walls are well clothed with fruit trees, especially Pears, which are admirably managed. Worthy of especial note also are two Morello Cherry trees, the finest trees and bearing the finest fruit we ever saw. They are not pruned after the ordinary manner of laying-in young wood, but are closely pinched and spurred, and the crops and quality are quite extraordinary. The glass structures are devoted to Grape, Peach, and Cucumber culture, in which Mr. Vinden excels. He is also equally at home as a grower of plants, of which many are required for the mansion; he is also successful as an exhibitor.

We have only given an outline of this exceedingly fine and well-managed place, but have a hope of being enabled to fill-in the details on a future opportunity.

PEARS—WINTER NELIS.

I wish to draw attention to another old Pear, Winter Nelis, which my experience leads me to place at the very top of the list.

It possesses every quality which the most fastidious Pear critic could desire. It is a sure cropper, the fruit is fine, on

well-established trees considerably over middle size, of the most delicious flavour and texture, second only, if second, in these respects to the very best Marie Louise. Then it remains in season longer than any Pear I know of.

I have had it in use from the end of November to the present time, and I have still a few left which look as if they would keep till next month. Another great point in its favour is, that it never decays at the core, it begins to go always from the outside.

It deserves a wall and should have one if possible; but I have it as a pyramid and the fruit is very good, hardly distinguishable, save in size, from that grown against a wall. But the pyramid is rather delicate and apparently liable to canker. My opinion of this Pear is so high that were I doomed to grow only one sort, it would certainly be Winter Nelis.

Easter Beurré, the crack winter Pear of the French, is worthless here. Whether from a wall or from trees in the open, it is by far the worst Pear that we grow in these parts.

My experience of Knight's Monarch is the same as that of your late correspondent's. The fruit refuses to ripen. Glou Morçeau, though it does fairly well in neighbouring gardens, is worthless with me, though a noble-looking Pear. I have given it a good trial on a south wall.

I am trying a good many other kinds, but cannot as yet give an opinion as to their merits.—L., *Cheshire.*

NOTES ON VILLA AND SUBURBAN GARDENING.

Continuing my remarks from last week upon the work to be now done in the kitchen garden, I advise that a crop of

Turnips be now sown; and although much cannot be expected from this crop, because, being early, there will be a probability of a portion of them running to seed, nevertheless, a few dishes of young early Turnips are worth trying for. The Early Stone and Early White Dutch are trustworthy sorts to sow both for the first and second crops. Sow in drills rather than broadcast, which gives a better opportunity to clean the ground.

Celery.—Of this most people grow some. Sow the seed in the following manner:—Make-up a small bed of prepared soil, and place a frame or two or three hand-lights upon it, and keep the sorts separate. Cover the seeds thinly, and gently water them, and not once allow them to become dry afterwards. This is very injurious to all small seeds, because when once the seed has begun to germinate, if allowed to suffer from the want of moisture its vitality is destroyed.

There are now too many sorts of Celery before the public, and in my opinion very little difference exists between them. There are tall and dwarf reds, and tall and dwarf whites, in many so-called varieties. I am satisfied with growing the following:—Williams's Matchless Red (tall) and Ivery's Red (dwarf), Cole's Crystal White (tall) and Sandringham or Tom Thumb (dwarf). After the plants are up and can be handled conveniently they may be pricked out in rows on a border of rich soil or manure, and grow there until wanted to plant in the trenches.

In small gardens, where space is an object, it is best to dig out the trenches at this time of the year, and fill them with manure pressed down and covered with soil. The space between the trenches can be cropped with Peas or Beans, or any vegetables which will come off before the soil is wanted for earthing-up; and again, if the trenches are dug 18 inches wide there will be room for two rows of Celery in each, thus by that plan space will be made the most of.

Parsley.—That which has stood the winter will now be starting into growth freely, but this soon runs to seed; therefore make a full sowing at once, either in drills by the sides of the walks or in a bed or border by itself. It is a crop which takes some time to come into use from seed, therefore it should be pushed on with all haste to succeed the winter crop. There are many good sorts of curled Parsley; Myatt's Garnishing seems to be about the best. The plants must be thinned-out in time and be highly cultivated to produce fine foliage.

Herbs.—If these are required in any quantity it is advisable to make plantations of them by deeply digging the soil and divide the ground into narrow beds according to the number of sorts to be sown; it is always best to have them all together. The seed may be sown and the plants allowed to establish themselves after being properly thinned-out. The sorts I allude to are Sweet Marjoram, Sorrel, Savory, Sage, Borage, Burnet, Thyme, Fennel, and Chervil, all hardy sorts; next comes Basil, which from being rather tender should be sown under cover and afterwards planted out.

Many of the sorts may be raised from cuttings put in under hand-lights, and be afterwards transplanted. These are Sage, Tarragon, Thyme, and Savory; while others may be propagated by division, such as Mint, Tarragon, Tansy, Pennyroyal, and Camomile.

Asparagus.—Where it is necessary to make new beds this should be done at once; and if they are likely to be permanent considerable pains should be taken in their formation. Asparagus likes a deep rich soil and plenty of moisture, yet the site must be well drained, therefore the soil should have plenty of manure trenched-in deeply and be well worked-up; if the soil is stiff add roadside sand to it.

There are two ways of planting. One is to strike out the beds 4 feet wide, with alleys 2 feet wide or more between each, and the plants put in rows; but another plan, and a good one, is to plant in single rows about 4 feet apart, and the plants 1 foot in the rows. They grow remarkably strong this way, and the shoots therefore come up large for cutting.

Old beds that have been covered up during winter should now have their spring dressing. Take off the soil down to the coating of manure, then dig that in carefully so as not to injure the crowns. Let the soil remain for a few days to dry, then rake it down and leave it even on the surface. Keep the beds very free from weeds during summer.

Globe Artichokes.—Like Asparagus, these must have a good, rich, and deeply-cultivated soil to grow in, and now is the best time to make a plantation. Plant in rows 3 feet apart, and the same from plant to plant. Rooted suckers should be taken from the old plants. They must be taken off very carefully, and after planting be well watered until they become established. A plantation will last seven or eight years. They produce their heads in June and July; but if they are wanted longer a few should be planted every spring, which will produce heads towards autumn.

Cabbages.—Fill-up the winter bed with plants from the seed bed, and afterwards earth-up the rows, as they are now beginning to grow; but before this the ground should have been pointed-up with a fork.

Tomatoes should be sown in mild heat and be grown to a good size for planting out in May. The same may be said of Capsicums, which ought to be planted in May in the warmest part of the garden.

Salsafy and Scorzonera need not be sown till the middle of April, or the plants will run to seed; and the sowing of Beetroot should also be deferred to the same time for the same reason.—Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

Allusion was made two weeks ago to the drying winds experienced this spring, and a continuance of them has allowed us to push forward operations without interruption; indeed, cultivators would be glad of a shower to moisten the ground which is being prepared for Potatoes.

We have just planted-out the Potatoes for earliest crop on a warm border. The sets had been placed in boxes, and not covered with cocoa-nut fibre refuse, so that young roots had been formed, and as the house was airy the eyes started strongly. Care was taken in planting them not to injure any of the young sprouts. The ground, which had been dug and manured in the winter, was forked lightly over, planting the Potatoes with a line as the work progressed. The sorts are Myatt's Early Ashleaf, Veitch's Improved Ashleaf, and Extra Early Vermont. This last is said to be so similar to Early Rose as not to be distinguished from it. It was very promising last year, having produced a very large crop with a disproportionately dwarf haulm. The Kidneys were planted 2 feet apart, and the American variety 18 inches only between the rows.

Made another sowing of Peas, dwarf sorts, such as Carter's Premium Gem, not requiring any sticks, and varieties requiring sticks—viz., Dr. Hogg, Fillbasket, and G. F. Wilson. Fillbasket is an excellent cropping sort, and will be the standard for all who prefer quantity to quality. G. F. Wilson is an early form of Veitch's Perfection, being ready for gathering quite a week before that excellent dwarf marrow sort, and in other respects it is equal to it. The dwarf Peas are being rapidly improved. Premium Gem is a decided advance on Little Gem, and Blue Peter is an excellent cropper; also, Mr. Laxton has Unique, which he says is 1½ feet high. They are sown half the distance apart that the other sorts are, and being put in the same time their relative cropping qualities will be determined.

If the Asparagus beds are not forked over they ought to be done at once. The usual way is to mark off the alleys between the beds, just forking very lightly between the rows, and adding to the surface of the beds any mould required from the alleys.

Sow Celery for the latest crops in an open place. In the northern districts Beet, Scorzonera, and Salsafy may be sown at once; but the middle or end of April is a better time in warmer latitudes. We are (in Essex) two or three weeks earlier with all crops that require a season to mature, if they are sown

at the same time, than in the south of Scotland or northern districts of England.

A second sowing of Broad Beans should now be made. If Brussels Sprouts, Savoys, and Broccoli for the earliest crops are not already sown they ought to be put in at once.

FRUIT AND FORCING HOUSES.

Pineries.—A high degree of temperature can be kept up in the fruiting house now if it is necessary to push on the fruits that are swelling, with a minimum of 70°, rising to 90° with sun heat; but the quality of the fruit is deteriorated by a high temperature, as it necessitates the house being kept pretty close, much artificial heat in cold nights, and proportionately more atmospheric moisture. Under such circumstances the crowns are frequently drawn-up out of proportion to the fruit. Should a day or two of bright sunshine occur after a dull period, it it as well to shade any fruits swelling-off with a sheet of paper during the hottest part of the day, say from ten to two in the afternoon. The fruit should also be tied to sticks to prevent it from falling over, for unless the fruit is quite upright the crowns will be one-sided.

ORCHARD HOUSE.

The Peach and Nectarine trees will not be in flower for a few weeks yet; the house has been well aired, and no artificial heat has been required at night, so that the lateness of the bloom will in all probability be the means of a good set. Plums and Pears have only been taken-in this week; however, a week or two of fine weather would cause all blossoms to open rapidly.

A little care is necessary in watering the trees, and there is more danger of the flowers dropping through the roots becoming too dry than if too much water should be applied. Thorough drainage is of the utmost importance, and there is but little danger to be feared from superfluous water when it drains away freely. Should the trees not be quite free from brown scale, now is the best time to look over them and have the scale removed, afterwards washing the place with strong soapy water.

Strawberry plants on the shelves do not as yet make much growth; the pots are watered alternately with weak liquid manure. They ought also to be watered with care, as the 6-inch pots are crammed quite full of roots; there is not much danger of overwatering any of them unless the drainage has become choked through worms working. When this is the case it is best to turn the plant out, and after clearing the crocks from mould carefully replace the plant as before. Worms may be destroyed by watering with clear lime water. Remove succession batches of plants to the forcing house as they are required. Any variety will bear rapid forcing now. President and British Queen are the best for late crops.

PLANT STOVE.

Climbing plants are growing freely, and if neglected now will be materially injured for the ensuing season. Those trained to the roof should not be allowed to twine into each other, nor should the young growths on the same plant be allowed to do this. Those growths that coil round the wires must also be untwined in order to train the plants as they ought to be done. Stephanotis, Ipomæa, Hoya carnosa, and all rapid-growing creepers should be looked over once a-week.

Pot plants of the same climbers should be trained in the same manner. The flowering growths must not now be trained round the trellis but to string, one end of which is attached to the trellis and the other to the roof of the house; this allows the leaves and flowers ample space to develope themselves, and when the flowers begin to open, the growths may then be tied into their proper places. The splendid plants of Stephanotis floribunda and other stove climbers exhibited at the metropolitan exhibitions are obtained in this way.

Not a single mealy bug should be allowed in the house. We can only recommend hunting them up with soft soap and water. It is mere waste of time and money to fancy that this pest can be destroyed by merely syringing the plants infested with any decoction.

Thrips are also very troublesome in the stove. Tobacco smoke will destroy them if it can be applied strong enough, but the leaves of many stove plants are very tender, and the young fronds of Ferns will not stand smoke. The best treatment is to wash the insects off with a sponge and soapy water. Red spider is kept in check by syringing the plants; those that cannot be syringed must be washed off by hand.

FLOWER GARDEN.

We have run the mower over the lawn and cut the grass edgings. It is now time that all the pleasure grounds should be in first-rate order, as a badly-kept lawn spoils the best place.

If any shrubbery borders have not yet been forked over it ought to be done at once. It may not be desirable to fork or dig where choice herbaceous plants are, but the Dutch hoe at least should be run through the ground, making the surface neat with a small rake. Rhododendron beds should be hoed and raked, and a dressing of rotted manure be placed over the surface. This practice is especially needful in dry districts, as it not only nourishes the plants but retains moisture. Hoed beds of spring-flowering plants, and also stirred the surface of Pink beds for the second time.

Auriculas are now throwing up their flower trusses, and it is desirable to shelter them from the east wind; in fine days the lights may be removed for a few hours in the middle of the day. Do not allow the plants to be exposed to rain; a slight shower would not injure the Alpine section, but the more tender florist varieties are much better under shelter.

Carnations and Picotees will be potted into the flowering pots as soon as we can attend to them. In the meantime the plants have been looked over, the withered leaves picked off, and a few plants that were attacked by aphis dusted with Scotch snuff.

Planted-out the first batch of Gladiolus bulbs. We have planted as early as the first week in March and once in February, but it is not desirable to do so, as the plants grow through the ground too early, and though they may not be cut down by spring frosts they are sometimes injured. To have a continuous display of this fine autumn flower until the end of October a succession of bulbs must be planted every fortnight until June. Do not neglect to place a little sand under and over the bulbs, nor should they be planted too deep; 2 inches of mould over the top of the crowns is quite deep enough for the largest bulbs. Small bulbs should not be quite so deep in the ground.—J. Douglas.

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Jersey.—May 5th, Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

Bath.—May 12th, September 1st and 2nd. Mr. B. Pearson, 13, Milsom Street, Sec.

Crystal Palace Company.—Flower Show, May 22nd; Rose Show, June 19th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.

Coventry.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.

Leeds.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.

Burton-upon-Trent.—June 16th. Mr. Wm. Shave, Bond Street, Sec.

Glasgow.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.

Fareham.—June 23rd. Mr. H Smith, Sec.

Exeter (Rose Show).—June 25th. Mr. J. N. Gray, Queen Street Chambers, Hon. Sec.

Wisbeach.—June 30th. Mr. C. Parker, Hon. Sec.

Maidstone.—(Roses), June 30th, at Vinters Park. H. Benstead, Esq., Hon Sec., Rose Club, Mill Street, Maidstone.

Spalding.—July 1st and 2nd. Mr. G. F. Barrell, Hon. Sec.

Durham and Northumberland.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.

Nottingham.—Rose Show, &c., July 9th and 10th. Apply to Alfred Kirk, Municipal Offices, Nottingham.

Tonbridge.—July 14th. Mr. W. Blair, Free Press Office, Hon. Sec.

Wimbledon.—July 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Sunnyside, Wimbledon, Hon. Sec.

Darlington.—July 16th, at Southend. William Hodgson, Sec.

Brecon.—July 22nd. Mr. W. J. Roberts, Sec.

Cleckheaton.—July 24th. Mr. S. H. Williamson, Hon. Sec.

Preston.—July 28th and 29th. Mr. W. Troughton, 4, Church Street, Hon. Sec.

Southampton.—July 31st and August 2nd. Mr. C. S. Fuidge, 32, York Street, Lower Avenue, Sec.

Ramsgate.—August 25th. C. D. Smith, Esq., 8, Marine Terrace, Margate, Hon. Sec.

Dundee.—August 26th, 27th, and 28th. Mr. R. McKelvie, 51, Reform Street, Sec.

South of Scotland.—To be held at Dumfries, September 3rd. Mr. J. Blount Dinwiddie, 11, Buccleuch Street, Dumfries, Hon. Sec.

TRADE CATALOGUES RECEIVED.

Louis Van Houtte, Royal Nurseries, Ghent, Belgium.—*Catalogue of Gesneriaceous, Bulbous, and Tuberous-rooted Plants.*

Ch. Huber & Co., à Hyères (Var.-France).—*Priced List of Ornamental Plants.*

J. Linden, 52, Rue du Chaume, Ghent, Belgium.—*Illustrated General Plant Catalogue.*

John Saul, Washington City, D.C.—*Descriptive Catalogue of New and Rare Plants, and General List of Florists' Flowers.*

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three

questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

POTATOES (*C. B. G.*).—The Lapstones you enclosed are affected by what is called "the Potato disease," about which so much has been written but no remedy ascertained.

CANKERED FRUIT TREES (*Jane*).—In the case of aged trees there is no cure for chronic canker. When it occurs on young trees a thorough drsining of the soil and a thin trsining of the shoots in the growing season to secure wood-ripening, are vital points to be attended to.

GAS-HEATED BOILER.—A correspondent, "J. H.," wishes to know the dimensions of the gas-boiler mentioned by "J. W." on page 178, and whether he thinks it would be capable of heating 150 feet of 2-inch pipe, also the amount of heat he was able to maintain in his greenhouse during the severest of the recent weather.

PRIMULA SINENSIS METAMORPHOSIS (*R. R. W.*).—We never before saw such a total change of the flowers. All are green; the petals are like the calyx. Stamens and pistils are all green, and even the ovary is leafy and green. We do not think the sport will be permanent.

GARDEN ENGINES (*E. B.*).—Any one of those advertised in our columns does its work well.

MOWING MACHINE (*M. A.*).—Write to Messrs. Green and tell them your difficulty with the chain. They will give you the information you need.

BONE MANURES (*F. J.*).—All in the list are good manures. We believe No. 6 the most durable.

IRISES (*W. A., Coventry*).—Any of the florists who advertise in our columns could supply fifty varieties if you explain to them what you require.

POTATOES FOR SEED (*H. K.*).—In the neighbourhood of Liverpool and Manchester all the varieties you name are grown. Inquire of the dealers in Potatoes there.

VICTORIA SAVOY (*A Subscriber*).—This is merely a form of the Dwarf Green Curled, and may be only a good selection. It is the best Savoy for general crop.

CAULIFLOWERS (*Idem*).—Walcheren, Lenormand's, and Veitch's Autumn Giant.

BROCCOLI (*Idem*).—Snow's Superb Winter White, Perkins' Leamington, Carter's Champion.

GOOSEBERRIES (*Idem*).—Rough Red, Whitesmith, and Warrington.

PLANTS FOR SCREEN (*M. C.*).—Having a hedge which will in due time give you the desired seclusion we should not go to the expense of a permanent fence of wire with climbers to cover, but content ourselves with a summer screen or two of such subjects as Scarlet Runners, Sweet Peas, and Nasturtium, the two last giving very useful flowers for cutting, and the first is one of the most useful vegetables. We should have all three, a row of each as follows, commencing from the back:—Scarlet Runners, a double row sown early in May, sowing rather thickly 3 inches apart in the rows, and providing with a double row of stakes, the stakes a foot apart every way, and in quincunx order, and with 7 feet stakes there will be little seen through it when covered. A double row of Sweet Peas mixed, and containing about half Scarlet Invincible, being sown at once and furnished with stakes 6 feet high, completing with an inner row of Nasturtium Tall mixed, and furnished with stakes 6 inches apart 5 feet high. This will give you a complete block by attending to the growths, tying and training to the stakes as required.

SURFACE PLANT FOR FERNERY (*Idem*).—The "small pointed-leaved Ivy" would grow luxuriantly in a stove fernery, but better far is Ficus repens, a very close-growing and rapid evergreen. It clings to walls or stone remarkably well, in fact will cover speedily any surface.

GRAFTING MAGNOLIA (*T. V.*).—The proper time to graft is in April just when the plants commence swelling the buds, and the safest mode is by inarching, which will take a year if not two to effect a complete union, the union of Magnolia scions with the stock being notoriously slow. Budding may also be accomplished in July or August. Cover the ligature with grafting wax, which is more neat, and is not so liable to crack as the usual grafting pigment of clay and cow dung. The leaf you sent is one of the forms of *M. grandiflora*, we think exoniensis, but the leaf is too small to judge with certainty.

CUCUMBERS AND MELONS (*X. Y. Z.*).—The Box-like border will be better than pots, but the depth ought to be not less than 9 inches, as in a shallow soil the roots are subject to suffer from drought. We should not give them all the soil at once, but add to it as the plants advance in growth. The netting, which we presume is wire, we should have fixed at a foot distance from the glass, and train the Vines to it. Ordinary netting we fear would not answer, and wire is not more costly than netting. It should be painted. Telegraph is a good Cucumber; more prolific but smaller is Munro's Duke of Edinburgh; Blue Gown is larger and very free; Tender and True has a very fine fruit, and is free-bearing. Melons: Meredith's Hybrid Cashmere, Cox's Golden Gem, Duke of Edinburgh, and Read's Scarlet-flesh; but if you have only sun heat Munro's Little Heath.

ECHEVERIA PUMILA (*C. W.*).—Judging from the small offset you sent us, the preceding is its name. It is one of many succulents at present so extensively in use for flower gardens, and is very suitable for an edging to beds. It is easily grown in light turfy loam, with a fourth of well-rotted manure and a sixth of sand or old mortar rubbish broken up small, good drainage being necessary. Water in winter carefully, keeping only from shrivelling, and during growth water more. It is a greenhouse plant, and should have a light airy position.

THINNING GRAPES (*Idem*).—It is difficult to describe this operation, there is so much diversity in the shape and size of berries, in their setting, and form of bunch. The shoulders of the bunches should be tied-up, and the smallest berries ought first to be taken out, and leave the largest and best three-quarters of an inch apart for the small round and oval-berried kinds, and an inch for those which have large berries. The berries inside the bunch should be removed, leaving them as much exteriorly as possible, and with plenty of room to swell. The earlier they are thinned after setting the greater prospect is there of large berries; but it must not be practised until it is clear which berries are taking the lead (some are small, and will be always so from being seedless), and those that are certain to attain a full size.

SEAKALE—CUCUMBERS (*Idem*).—It is not proper to blanch Seakale the season of planting, but it should be allowed to make a good growth, and in the winter following it may be forced, or blanched by covering with pots, and then with litter, or it may be blanched by covering with ashes or any light material. Liquid manure for Cucumbers may be made by a pack of sheep droppings to thirty gallons of water, and the same quantity of cow dung, horse droppings, and soot to twenty gallons, or 1 lb. of guano to the latter quantity of water.

CYCLAMEN PERSICUM PLANTING OUTDOORS IN SUMMER (*G. S.*).—We do not recollect in what number the planting-out of these plants is recommended. After the middle of May the plants may be turned out of the pots in the open border in light soil, and there they may remain until August or early in September, when they should be potted and placed in a cold frame.

MUSK TREE (*Idem*).—The spray is, we think, Guarea Swartzi, which is a stove tree from Jamaica. The whole plant has a strong odour resembling Musk, and so has Guarea grandiflora, neither of which are in general cultivation. Its foliage is good, and its perfume renders it very desirable. Propagation is effected by cuttings of ripe shoots in April or May in sand under a bell-glass in brisk bottom heat. It is not at best other than a tardy-rooting subject from cuttings, and even layers root slowly.

CYCLAMEN PERSICUM (*An Amateur*).—Sow the seed at once in turfy loam, leaf soil, sandy peat, and silver sand equal parts, and cover about a quarter inch deep with fine soil. Place in a hotbed and keep moist. The plants will soon appear, one leaf first, then two, and when they are showing the second pot them off singly in 3-inch pots in the same compost, but with only a sixth of silver sand. Put so that the corms are just covered with soil. Return to a hotbed, or place on shelves in a house where there is a brisk heat and moist atmosphere; keep moist, but avoid making the soil sodden by too heavy and needless watering. They do well in a stove, a Cucumber house, or anywhere near the glass in a warm and moist house. When they fill the pots with roots shift into 4½-inch pots, and again as these fill with roots into 6-inch, selecting the largest for this size. If kept growing during the winter they will flower well next spring, but to do this they require a cool stove or warm greenhouse temperature.

PROPAGATING SHRUBS (*West Coast*).—Your soil will grow almost any and all kinds of shrubs. To give you names would be to enumerate an extensive list, which you may do quite as well as ourselves from any catalogue. Peat is the best soil for Rhododendrons, and they will flower this season if transplanted now. Sweet Bay cuttings under hand-glasses in a shady border at the end of August or early September. Portugal Laurel by cuttings, with about an inch of old or last year's wood, in a shady border in a sheltered situation about the middle of September. Aucuba same time and position, but better under a hand-light or glass. Laurustinus in sandy soil at end of September in a sheltered shady border. Pyracantha, layers in autumn. Pyrus japonica, suckers, which spring freely from the root; layers in autumn; or ripe-wood cuttings after the leaves are fallen. Mahonia, Berberis Darwini, B. dulcis, all three from seed sown in spring, of which you may save plenty of seed, only keep from birds; or by suckers, but seedlings are every way preferable. Box by cuttings about 6 inches long in sandy soil in a shady border in September. Enonymus japonicus, cuttings of ripe shoots in August under a hand-glass in a shady border in sandy soil. Arbor Vitæ, cuttings in sandy soil under a hand-glass in a warm shady border, but better by seed sown in April in a warm border. Junipers by cuttings in September in sandy firm soil in a shady border under a hand-glass; or seeds, which do not vegetate under a twelvemonth, often two or more years. Yews, cuttings in sand in a shady border, and a heel of old wood; better by seed, which will not appear until the second or third year. Escallonia, cuttings of shoots in August in sandy soil under a hand-glass.

ROSES—PRIMULA JAPONICA (*Idem*).—For your soil we should have the Roses on Manetti; upon own roots they do not grow nearly so vigorously. They will not answer upon Manetti stocks for standards; those will need to be on Briar stocks. Primula japonica flowers at this time of year, April, and May, and it is perfectly hardy. Primula cortusoides amœna is increased by division, as you will see particularised in the article to which you allude.

DOUBLE WHITE VIOLETS (*Flora*).—The double white Violets mentioned in Bacon's Essays as flowering at Easter were no doubt the same as those now cultivated under that name, and which may be had of any of the principal florists advertising in our columns. Queen of Violets is large, white with purple blotches, and very sweet.

GERANIUM LEAVES CRUMPLED (*Idem*).—The leaf sent is not diseased, but the atmosphere in which they are growing is too cold and dry, the crumpled state of the leaves being caused by a chill or sudden check to growth. There is also an appearance of thrips having been active upon them, which may be destroyed by fumigation with tobacco.

SPARAXIS NOT THRIVING (*Idem*).—The treatment of these plants in pots is as follows:—Plant in September or October five or six bulbs in a 5 or 6-inch pot, using a compost of equal parts turfy loam, sandy peat, and leaf soil, with a sixth of silver sand. They should have the soil made firm about the bulbs, inserting them about an inch deep, and place in a cold pit or frame, plunging in ashes, and keep cool, no water to be given until the foliage appears, then give it sparingly, increasing the supply with the growth. Early in March they may be removed to the greenhouse, placed on a shelf near the glass, and be duly attended to with water until in flower. We apprehend your plants have been kept at a distance from the glass, have been too heavily watered, and not had enough light and air.

POULTRY, BEE, AND PIGEON CHRONICLE.

A VISIT TO MR. VANDER MEERSCH.

"I HAVE over four hundred birds to show you, and shall be very pleased for you to see them. Balham is the best station to reach me by, as more trains arrive there than at Tooting. Just drop me a line." Thus wrote Mr. Vander Meersch many months ago, but no opportunity came for my accepting the invitation until recently.

Now, there are many stations at which the traveller's only wish is to get *on*, and the wish to get *out* never enters his head. Many such are around London, but there are others where the country looks so pleasant, or the town or village looks so bright, that one quite longs to get out and take a ramble. Such a one

is Balham. Often and often had I passed it in spring, and autumn, in summer, and especially in winter, but it always smiled a welcome. Pleasant-looking treey Balham! for after all the fine trees were what had captivated my eyes, and made we wish to see the place.

But what a winter we have had! How cruel to man and beast, and bird! Oh, that snowy freezing December, and February still worse to bear because of the mild January preceding. Surely March will make amends! but March 1st piercingly cold, with north-east wind, no sun, no cheerfulness. March 2nd just the same. March 3rd rather worse, because of little spiteful snowflakes that almost blind one. What days to walk up Piccadilly with the wind in your face! Metropolitan railway stations usually cheerful, but cheerless now, with shoeblack boys having no customers, for people dare not stand still and take bronchitis. March 4th comes, and—"Why, really, you don't mean it, do you? there you are at last, my old friend, Sol." Positively there at ten o'clock is a little sunshine, more at eleven, and by noon, when I reach Balham station, it is really a pleasant bright March day.

Now has come the time at last to walk through the place I had so often admired in passing. How broad, and bright, and pleasant the street is! how well kept the houses and gardens!

There is my friend, a butcher's boy (N.B.—Always ask your way of a butcher's boy, for he is a walking, or rather driving, local directory). I pause till the said boy, rosy and plump as his beef, has ceased his flirtation with that pretty maidservant. Just as a hungry man is an angry man, so an interrupted lover is liable to be cross. "Will you tell me where Mr. Vander Meersch lives?" "Why, sir, at Lower Tooting." "Well, is this Tooting?" "Some calls it so, but I call it Balham, and Upper Tooting begins at the 'Wheatsheaf.' Go straight on for a mile, cross a broad way, and on the left opposite, a big red-brick house, is Mr. Vander Meersch's." Now, there's a butcher's boy for you; his information clear, concise, and easily remembered. Had I interrupted his love-talk I should not have had such a good direction. Note.—Always be judicious, and do not speak at wrong times. Attention to this and like matters make a man get on comfortably in life. Discretion oils the wheels of life and makes the machine run on smoothly.

Thanks to that butcher boy my troubles are at an end. I stroll on in enjoyment, not in doubt. Presently I come to the "Wheatsheaf," for there is its sign, and there in the door the host. I come soon after to the broad crossway. There's the large red-brick house, just one of those you rarely see anywhere except near London. Why it is I know not, but around London there are grand red-brick mansions, their colour toned by time, most pleasing to the eye, giving an idea of warmth and comfort which no stone can give. Some stone for dwellings chills, as, for instance, all who know Aberdeen feel chilled when walking the streets by the cold grey granite of the houses.

Would that men would now make such good red brick as in the years when Hampton Court was built, or when many such houses were as the one I now look at. Directly opposite I see Mr. Vander Meersch's name on a wicket, and walk in through a nice roomy garden to a most snug old-world romantic home (for home is the only word), named "The Walnuts"—suitable name, for walnuts came to England in Henry VII.'s reign. Soon I enter a regular cosy parlour; and though I am as yet alone I know it is Mr. Vander Meersch's, for on a side table is a stuffed Black Trumpeter, a bird that in life I remember well, and a grand bird it was. There, too, on a table in the window is a stuffed White Jacobin, another grand bird; but as yet we Pigeon fanciers have not found a bird-stuffer who is a fancier, and therefore no dead specimen has justice done to it. Above me chirps a good Norwich Canary; at my feet is a toy terrier, while a black retriever makes love to my hands. Around me are glorious hyacinths, and I sit and wait for the master's arrival, feeling a fancier in a fancier's home.

I do not wait long, for Mr. Vander Meersch soon arrives, and with him I begin the tour of his premises. He is particularly fortunate in having so much space, and yet so near London. Before the house lies a square of lawn all—house and lawn—within walls. On the lawn are fowls enjoying a ramble. Two sides of the lawn running around the interior of the outer wall are wooden poultry houses and runs, each a semi-detached villa, with a run at either end of the block; two houses and their runs, then two more, and so on all round the two sides. They are very neat erections and do not look awkward, as they are low-roofed.

Mr. Vander Meersch manages to keep thirteen different varieties of fowls, in size varying from Black Cochins to Game Bantams. There were Hamburghs, too, of every variety. I was glad to see the Black Cochins, for they are a class which need much to be taken up by fanciers. We have plenty of good Whites, but Blacks are few indeed. I stroll round admiring the neat arrangement of the houses and the excellence of their inmates. Indeed the whole plan is admirable, including the exercise-lawn in the centre, with flower beds protected by wire.

Come we next to the Pigeons, looking up as we pass to a loft above a stable—a deserted loft now, for it brought sad reflections, for the rats forced their way in and destroyed many birds. First within an enclosure I come upon Pigeons kept on the pen system, almost as Rabbits are, the birds sitting in one part or division and living in the one adjoining. In these I found good Fantails, tame as cats from constant companionship with their owner, large Runts, small African Owls, also Jacobins, and they were Mr. Vander Meersch's Jacobins that I particularly wished to see. He is breeding not only for Blues but Silvers, and is on the way to success.

These colours will be a very agreeable addition to our shows. We have Red Jacks and Yellow Jacks in abundance and of admirable quality. Then come Blacks, striking by the contrast of the white head and black hood, but other colours there might be. Now, as I said, Mr. V. is breeding for Blues and Silvers, and what we have begun to see good—viz., Whites, as witness that beautiful White Jack shown by Mr. Fulton at the Bristol Show. The difficulty with the White is of course getting rid of the bull eye and obtaining a good pearl eye in its place, as bull eye and white feather will go together; this, however, may be done. There is another colour which I used to see—viz., Mottles, which I should again like to be shown.

A correctly mottled Jack would be as good a colour as in Tumblers, and the old fanciers had Reds, Yellows, Blacks, Blues, and Mottles. Duns would hardly be a desirable addition, but a clear Blue as good in colour as a Dragoon would be a great addition, for I fully believe in old Girton when he says "Jacobins are by far the prettiest Pigeons of the Toy kind." We may look for first-class Blues, Silvers, and Whites in a few years from Mr. V.'s stock. Next I come into the largest compartment of all for the Pigeons, some 30 feet long by perhaps 10 wide, all roofed in, and with a close wire front. Around me are the shelves, on the old principle of being open, save having a blind to hide the nests.

All sorts of Toy Pigeons are before me, and some that are not Toys—Turbits, Nuns, Barbs, Trumpeters, and Dragoons, and a few Shortfaces. I handle several, and see Mr. V.'s plan of matching-up for the season. To show the difficulties which fanciers have to contend with, and true fanciers overcome, I am shown a most perfectly Shortfaced Jack, but—it has orange eyes; then a Black with a chain and hood of marvellous length, but—half its face is black and the beak very pleasant-faced. But these birds will form ingredients from which will come grand and perfect prize birds. And herein lies the ceaseless pleasure of Pigeon fanciers; they have always a "Hill Difficulty" to meet and surmount. I go on to other like, but less lofts, and see many birds, upwards of thirty varieties being kept by Mr. Vander Meersch. Among the Fantails was a blue-laced hen, a *rara avis* indeed. Wiltshire met me too, for among the White Pouters was one from Mrs. Ladd of Calne.

Having made the tour of the premises to the great disgust of a most savage bull-terrier, who regarded me probably as the well-dressed head of a gang of burglars who had come disguised as a clergyman in order to spy out the weak point for attack. Oh, that bull-terrier, with his chain shortened to save my calves, which quivered with fear, as I had to pass very near him once or twice!

Returning to the house, having perambulated the whole premises and seen everything down to horse, Alderney cow, and that terrible dog, I sit down to lunch in a room hung round with old Mr. Wolstenholme's portraits of prize Pigeons; almost every fancier has them, and some of them are still good, although time and fanciers have made great strides onwards since they were drawn, as in the Trumpeter and Pouter; but the Lance Fantail and the Black Short-faced Tumbler are excellent, and will please for ever. Chattering over luncheon and talking Pigeon-talk, I am next shown by Mr. Vander Meersch his prizes, cups, and, what are much more useful, a silver tea-apparatus, &c.

But the day wears, and I must be in Wiltshire by night. On my way to the station I am shown peeps into the vast houses for orchids, azaleas, heaths, &c., in Rollisson & Son's nursery, with which Mr. Vander Meersch is connected; thus he is a sort of walking *Journal of Horticulture*, for his life is spent among flowers and birds. Happy man to be situated, and not "pent in a populous city." But time and trains wait for no man, and with a hearty shake of the hand with my pleasant Belgian friend I hasten to Balham station, having enjoyed greatly the best part of a fine March day with Mr. Vander Meersch.—Wiltshire Rector.

The Bath and West of England Society meet this year at Croydon. The Exhibition opens on May 31st, and closes on June 4th. Croydon being so quickly accessible from London, if the weather proves favourable the visitors will be numerous. The poultry prizes are liberal, and there are fifteen £5 cups. We are sorry the Society adheres to the injurious rule of requiring the birds to be delivered on the Saturday. We know to our cost that the Sunday frequently spoils the looks of many of the birds before the judges come round, for the pens are made very dirty. We wish the Society would admit the birds on

Monday, to be judged on Tuesday. Is it too late even now to have this remedied? The schedule, too, in other ways is behind the times. Every pen must be sent in a separate basket. We had hoped this rule was to have been obliterated from all schedules. Then, Black Hamburghs, which generally muster strongest of the Hamburghs, are left out entirely. Game Bantams are huddled into one class with only two prizes, and there is no Bantam variety class. Pigeons have sixteen classes, and no cups. We are glad to see one of those sixteen is for our friends the Archangels. No colours are divided; but Turbits of all colours, Tumblers of all breeds, and Dragoons of all sorts have each to go to their one class.—W.

POULTRY-SHOW EXPENSES.

We are frequently asked whether poultry shows usually are self-supporting, and what expense a show of a fair size entails? We have before us the balance-sheet of a show held during January last, and from it we may gather some of the items of expense connected with such exhibitions. We must first, however, say that we do not think shows are usually self-supporting. The expenses are legion. The outer world and exhibitors generally have no idea of the large expenditure a poultry show entails.

Looking over the lists of shows held during the past ten years we find very many which only continued two or three seasons. They collapsed from the mere fact that the committee would not endure loss year after year. There are, however, so many towns and villages ready to have a show whenever a suitable date occurs, that those discontinued are not missed. Of course many summer shows have been going on for many years, and seem to thrive, but they are generally connected with an agricultural association, and conduce to each other's prosperity. Then there are some shows which, perhaps, from careful generalship and genuine hard work do succeed and fight their way well, and become annual events. Of such a show we cannot have a brighter example than that held at Oxford.

The Crystal Palace, Birmingham, Manchester, Bristol, and such-like shows we look now upon as national institutions; but poultry exhibitions generally we do not think are profitable. They commence with poultry, then a few Rabbits are added, then cage birds, and then cats to make the family party happy. But all these latter pets are merely added as elegant baits to tempt in the outside world, who, busy in the daily avocations of life, pass the very doors of the exhibition without turning in, regardless of cocks crowing and of Canaries singing. Even these baits are short-lived, and the people, when it ceases to be a novelty, neglect to come. Then the show puts up its shutters from want of local support, without which shows cannot live.

We often think the inhabitants of some places are more energetic than others; what else can account for the extraordinary manner in which some poultry show rooms are filled with visitors, and others literally empty? For examples take Bristol and Oxford. We have been in the Drill Hall in the former city and not seen more than a score of people, and the whole of them almost fanciers from a distance—strangers to the town, and this is, we fear, the state of things generally at Bristol; while we have been present at every one of the evenings of the three Oxford Shows, and on each occasion found the buildings so filled to overflowing that literally it was impossible to move, and the whole crowd kept surging round the rooms unable to see a feather. This we should like to see at all shows. We do not mean an inconvenient crowd, but each show well supported by its townspeople.

An exhibition causes much money being spent in the town, and in return the residents should all do their best to make it a success. When we are asked for advice about establishing a poultry show we always strongly recommend having two committees: the one composed of a few working fanciers who really know what to do and are willing to do it, and the other consisting of as many members as possible, each to guarantee £1 in case of loss. This stimulates them to promote the interests of the show and to enlist visitors. By it a large sum of money is guaranteed in case of debt, which falling on many pockets makes the sum for each to pay quite a nominal one, and so does not prevent another trial being made. This is a good plan, and we have known it to work well.

Too large a working committee is most disastrous. Everyone thinks he knows best, and nothing is arranged to the satisfaction of all; but on the working committee there must be some real fanciers—men who know the ways and movements of exhibitors; a committee of novices fall into all kinds of mistakes and needless expenditure.

The show of which the balance-sheet we have before us was a first exhibition, and comprised poultry, Pigeons, cage birds, Rabbits, and Cats. We find the entries amounted to very nearly a thousand, which is a fair, though by no means a large, number for the amount spent in cups and prizes, which amounted to £195. The entry money came to about £170, making £25 difference between the two. We always like to see the fees pay the prizes, and this should be the case. Here, however, the dates were badly chosen, and a Sunday absurdly included, which of course lessened the number of entries. We find the charges for about eight hundred pens came to close on £40, nearly 1s. each. Judges' fees amounted to £19, which we think reasonable, for the staff was a large one and good, consisting of no less than six gentlemen. Labour, materials, attendants, and food came to about £80, and printing, advertising, and posting, £40 more. The rent of rooms and refreshments for judges and staff about £30, making a total expenditure of nearly £400. We must remember that the secretary was an honorary one, and did not cost the society anything.

This, then, is the expenditure for a show of about a thousand pens. We do not consider that it was extravagantly worked, nor peculiarly economically; but it was well done, and the arrangements were good. Against the outgoings we find £143 taken at the doors on the three days of the show, £170 for entries, and about £32 collected in the neighbourhood for cups and pieces of plate, a great part of which was contributed in half-crowns, the energetic honorary secretary having opened a ladies' subscription list of 2s. 6*d.* each, and so collected a goodly part of the £32 without any especial call on anyone's pocket. We can recommend very strongly this most useful and successful plan of obtaining some prize plate to give a schedule a healthy look; and then, lastly, there were about £10 commission on sales. Thus the receipts only came to £350 against an expenditure of £400, and a debt of £50 remains. Now, had there been only a small committee this debt would most likely have prevented their holding another show; but the two committees existed, and the second being a large one, the loss will be equally distributed among all of them, and so no one will really feel much inconvenienced, and they are, we believe, already looking forward to holding their second exhibition.

One word in conclusion to exhibitors and the fancy generally. We think all should do their best for shows, not only in supporting them with entries, but by being as courteous and civil as possible to the show authorities, for they are mostly men who from genuine love of the feathered world give much valuable time and a large outlay of money to promoting the welfare of the fancy, reaping, in many cases perhaps, as a return only rude treatment from those whose interests they have been serving.—W.

HOUDANS LAYING.

I am sorry to see in the last two numbers of the Journal complaints of Houdans not laying.

From twenty pullets I have had an unfailing supply of eggs since November; only two or three a-day in that month and December it is true, but always some eggs. Now they are in full laying.

I feed on bruised oats, small wheat, and corn dust slaked with pot liquor, and mixed with kitchen scraps, given warm in the early morning and again at noon, their last meal being the best whole oats.

They have a large grass run, but it has proved a snow run mostly this winter for them, yet they have laid well, fine, large, rich eggs.—Sabrina, *Aberdeen, N.B.*

I am much obliged to your correspondents for their notice of my questions about Houdans. Would not some more breeders give us a fair and candid statement on this point? for I wish to be assured about it before I break up my yard. They have other good qualities, and I admire their appearance; but if they are faulty in this respect I must change for some other breed.—D., *Deal.*

STANHOPE (NEAR DARLINGTON) POULTRY AND PIGEON SHOW.

This was held in a large tent near the railway station on the 20th inst. The Show, although only small, contained some very good birds. The *Game* were excellent and the entries large. In single cocks there were thirteen; both prizes being taken by the same exhibitor with Duckwing and Brown Red, each superior, stylish birds. The three highly-commended pens were Brown Reds. In Black or Brown Reds (cock and hen) both prizes went to the latter colour, very good close-feathered birds. The Duckwings were a good class, and besides the prizes two pens were highly commended. The first-prize *Spanish* won the cup for the best pen in the Show, and also the cup for the best pen within three miles of Stanhope. They were very good, and shown in fine condition. The cup for the best pen of *Dorkings* went to Darks. Neither of the Dorking classes were good, and the cup certainly was of more value than the birds. The *Hamburgh* classes were very fair for the locality, but they might have been better; many of the combs were faulty. The Game *Bantams* were of medium quality. In pairs of hens a capital pair of Brown Red Game were first, a perfect match, and good in all points; second went to Grey Dorkings;

and four pens were highly commended. The *Duck* class was a very creditable one with thirteen entries, Aylesburys were first and Rouens second; and six pens highly commended. The first-prize *Turkeys* were very good, and in capital condition.

The PIGEONS were not large entries. The cup for the best pen went to a very good Carrier, and the next best was a Barb belonging to the same exhibitor.

The RABBITS were not first-class with one or two exceptions. The total number of entries was 165.

SPANISH.—Cup, J. Craig, Bridgend, Frosterley. 2, T. Flintoff, Ruby, Stockton-on-Tees.
DORKINGS.—*White.*—1, Master J. Morley, Stanhope. 2, H. Pease, Stanhope Castle. *hc*, W. Love, Wolsingham. *Any other variety.*—Cup, J. Lodge, Woodcroft.
GAME.—*Black-breasted and other Reds.*—1, M. Bainbridge, Stanhope. 2, J. Gibson. *Any other variety.*—1, J. Gibson, Stanhope. 2, J. Fenwick. *hc*, M. Bainbridge; J. Rowell. *Any colour.—Cockerel.*—1 and 2, M. Bainbridge. *hc*, G. B. Bell, Leyton; J. Sanderson (2).
HAMBURGHS.—*Golden-spangled.*—1, W. Simpson, Pyeclose. 2, W. Urwin, Edmondbyers. *Silver-spangled.*—1, G. Barkas, Crawleyside. 2, J. Sanderson. *hc*, G. Barkas; H. Surtees, Edmondbyers; J. Hutchinson.
HAMBURGHS.—*Golden-pencilled.*—1, A. G. Michel, Bishop Auckland. 2, G. English, Frosterley. *hc*, G. English; J. Foster, Hedleyhope, Towlaw. *Silver-pencilled.*—1, J. Foster. 2, W. Jopling, Bridgend, Frosterley. *hc*, W. Simpson; M. Ridley; W. Jopling.
POLANDS.—1, J. Jackson, Hedleyhope, Towlaw. 2, W. D. Maddison, Sunniside.
GAME BANTAMS.—*Black-breasted or other Reds.*—1 and 2, W. Gray, Towlaw. *Any variety.*—1, J. Hutchinson. 2 and *hc*, W. Gray.
ANY VARIETY.—*Hens.*—1, T. McKenzie, Stanhope. 2, T. Curry, Wooderoft. *hc*, G. B. Bell; M. Ridley; J. Fenwick; J. Sanderson.
ANY OTHER VARIETY.—1, J. Littlefair. 2, J. Rowell. *hc*, G. B. Bell.
DUCKS.—1, W. Love. 2, W. Simpson. *hc*, W. Love; G. B. Bell; J. Bright, Bewley; J. Buston, Wolsingham (2); T. Briscoe, Frosterley.
TURKEYS.—1, H. Pease. 2, J. Currey. *hc*, W. Love.

PIGEONS.

CARRIERS.—Cup, W. Taylor, Sbotley Bridge. 2, S. & W. Coulson, Wolsingham. *hc*, S. & W. Coulson; R. & T. Sanderson.
BARB.—1, W. Taylor. 2, J. Young, Bishop Auckland.
JACOBINS.—1, G. Trueman. Fore Boudgate, Bishop Auckland. 2, J. Young. *hc*, J. Best.
TUMBLERS.—1, S. & W. Coulson. 2, R. & T. Sanderson.
ANY OTHER VARIETY.—1, J. Stephenson. 2, J. Young.

RABBITS.—1, M. M. Maughan, Bishop Auckland. 2, H. Pease. *hc*, A. Friend Bishop Auckland; H. Thompson.

Mr. James Dixon of Bradford was sole Judge.

NATIONAL ORNITHOLOGICAL ASSOCIATION.

NOTICING in your report of the Crystal Palace Bird Show some reference to the "N. O. A.," which I interpreted as meaning the National Ornithological Association, may I ask what action that Association intends taking as to the holding of an exhibition or exhibitions?

Some time back I was solicited to become a member for which I paid a sovereign, receiving in return a card of membership and a code of rules, with the understanding that certain shows would take place during the latter part of 1874. "Judging by *points*" appeared to be the hobby-horse of the Association. Whether it has made a *full stop*, or what is intended to be done, I am at a loss to know.

If no action is taken by those at the helm of the Association as to the holding of the promised exhibitions, I shall most certainly decline to continue my subscriptions.—ONE IN THE DARK.

FROSTERLEY SHOW OF POULTRY, &c.

THE eleventh annual show of poultry was held at Frosterley on the 27th ult. The Exhibition was in all respects a good one. We may particularly notice the *Game* classes; they were very superior to most local shows. The number of entries in the poultry and Pigeons was 212, and in dogs and butter 98.

The cup for the best pen shown by an exhibitor in the parish of Frosterley was won by a very good pair of Dark Dorking hens. The first-prize *Spanish* were very good, the others only medium. The *Andalusians* (for which there was a class) were very poor, all evidently a cross of the Spanish. *Dorkings* and *Cochins* were fair birds. The *Brahmas* mustered thirteen entries, some good birds in the class. The *Hamburghs* were about an average in quality. The first-prize Golden *Polands* were remarkably good, the cock's crest the best we have seen for a long time.

The *Duck* classes were well filled; both the Rouen and Aylesbury were very good, particularly the prize birds. *Geese* and *Turkeys* large, and in good condition.

The *Pigeons* had only four classes, consequently the entries were not numerous; but the prize birds were very good.

SPANISH.—*Black.*—1, J. Craig. 2, T. F. Newby, Stockton-on-Tees. 3, M. Amor. *Blue.*—1, J. Craig. 2 and 3, J. Holroyd.
DORKINGS.—1, T. F. Newby. 2, J. T. Proud, Bishop Auckland. 3, T. Currah, Woodcroft.
COCHIN-CHINAS.—1, Mrs. Ridley, Peakfield. 2, G. B. Bell, Coldwell. 3, E. Pickering, Bishopley.
BRAHMA POOTRAS.—1, W. T. Whitfield. 2, F. E. Gibson, Middleton Teasdale. 3, G. Atkinson, Etherley.
GAME.—*Black-breasted and other Reds.*—1, C. E. Morgan, Bishop Auckland. 2, M. Bainbridge, Stanhope. 3, W. Younghusband, Darlington. *Any other variety.*—1, J. Gibson, Stanhope. 2, T. Horne. 3, C. E. Morgan. *Cock.*—1, J. Harker, Crook. 2, C. E. Morgan. 3, J. Gibson. *Cockerel.*—1, W. Younghusband. 2, C. E. Morgan. 3, G. B. Bell.

Mr. James Dixon, Bradford, acted as Judge.

A FRAGMENT ABOUT POUTERS.

GERALD.—The fish seem to have left off feeding, Walter, for I have not had a rise for some time. Come, let us sit down beneath the shade of this tree, and see what Margery's basket contains.

WALTER.—Here are seven good speckled trout, and more to follow I hope. We will rest awhile and pay our respects to that great pie, drink a cup, and smoke a pipe thereafter.

GERALD.—How does the young blue get on, Walter? It is three weeks old now, and you will see how its markings are.

WALTER.—It will be well pinioned on each wing and clean on the limbs, I think; but I fear for the bib, as the highest feathers on the breast are still white. How do your young red pair thrive?

GERALD.—The biggest and best marked is, I fear, to be off-colour, for the tips of its feathers are lighter than I like. The other with the bishop wing is sound in colour, and will, I think, moult into a blood red.

WALTER.—My black hen laid last night; but the yellows have broken their eggs again. I had no change for them; but the next time I shall shift their eggs about till hatching time should I not have a pair of feeders lay within a day or two. The yellow cock is a heavy sitter, and works his nest down to the bare boards. Let me hear the lines you say you composed, Gerald; but wait till I fill and light my pipe.

GERALD.—The lines are of little account, Walter; but I will let you hear them as you wish. I found an old work at the stall of a dealer in old books the other day, that treats of fancy Pigeons, and after reading it by the fire I fell a-musing over my pipe, and wrote down the following, which I shall call

THE FOUR POUTING PIGEONS.

First comes the yellow Pouting cock,
Clad in his suit of golden-coloured hue
And markings all complete, that you
Might scarcely pick a fault in him throughout.
Bright as an orange and as round, his crop
Is marked with crescent ending fine at points,
Nor reaching to his eyes to blur their fire.
Next see the red, with hollow taper back,
And well-set limbs inclining at the hock,
His downy feathers fitting like a sock.
Nor long toe feathers doth he any lack.
Red as the flowing heart blood of the slain
His jerkin is. But, look! here comes the black.
So burnished in the sunlight doth he seem,
Rather than black, to be of glossy green.
Rose-pinioned on each wing, sharp cut below,
No blaze face nor foul thigh marks doth he show.
But yet the blue, of hue like summer sky.
And markings white, like fleecy clouds thereby.
His purple neck, and wing bars all of jet;
Across his tail a darker band is set.
Tight-shouldered, narrow-girthed, flights broad and long,
He walks with stately mein, nor rumps along.
Neither too thin in limb, nor yet too rough,
His joints are not too straight, but bent enough.
For beauty, stylish shape, and symmetry,
Though last he comes, the king of all is he.

—POUTER ON THE BRAIN.

OWL PIGEONS AND DRAGOONS.

I TAKE up my pen with much pleasure to reply to Mr. J. C. Lyell and "BUBO." I say with *much* pleasure, because both writers have a great regard, Mr. Lyell particularly, for the authority of the old writers on Pigeons—the, so to speak, "fathers of the fancy."

Pigeon-culture is not a science of yesterday, for its great authority dates back to 1735; and though I hail every true improvement with pleasure, yet we must always advance on the old lines. To illustrate my meaning by an instance of the opposite character I take a pert and perky letter which appeared recently in a contemporary on the Dragoon. The writer states

that "Dragoons are a distinct breed—as distinct as the Short-faced Tumbler is from the Runt," and that "a Dragoon should be a large bird, even larger than a Carrier;" in utter ignorance that Moore in 1735 wrote, "The Dragoon is absolutely and without dispute a bastard strain, being bred originally from a Horseman and a Tumbler," and "the Horseman," from which it is bred, he says, "is smaller than the Carrier." Much more so, of course, is the Dragoon, which point, however, is settled by Girton, who wrote, "The Dragoon is a lighter and smaller-made Pigeon than the Horseman." I could quote more mistakes from this said "pert and perky letter," but I have quoted enough to show that ignorance ought never to set up as teacher; indeed, ignorance as to what a Dragoon is according to the great authority is the foundation on one side of the whole discussion. Now, in Mr. Lyell I have one who possesses, reads, and respects Pigeon authorities as much I do myself. We can, then, discuss the nature of the Owl on the proper basis of rightful authority.

Mr. Lyell correctly states that in the Treatise of 1765 it is written, "The Owl is, according to Mr. Moore, a small Pigeon, very little larger than a Jacobin;" but, unfortunately, Moore states nothing of the kind. This mistake of the author of the Treatise is pointed out by Mr. Tegetmeier (*vide* "Pigeons," page 139), who, after quoting the words of the Treatise about the Owl, writes, "This statement of the writer is erroneous, for Mr. Moore says nothing whatever of the size of the Owl, but makes the assertion quoted concerning the Turbit."

Moore was undoubtedly a good fancier and correct writer, and his work was original. He was a scholar, and a friend of Pope the poet, but he died soon after he published his book; and after thinking much on the subject I have come to this conclusion concerning both the author of the Treatise and Girton—viz., that they were simply a couple of booksellers' hacks. The former quotes Moore throughout without acknowledgement, which is the conduct of a dishonest man; and Girton, also known as Thompson, most amusingly transposes the sentences in order to avoid being the same. Sometimes the beginning is put at the end, and the varieties do not follow in the same order. The cards are cleverly shuffled, but, as a rule, they are the same cards. A bookseller in those days found there was a demand for a work on fancy Pigeons; they got hold of Moore's book, got a competent writer, and he got hints from some fanciers and some pictures, and redressed old Moore, and, as a rule, the whole was done wonderfully well, but as to the size of the Owl a mistake was made.

The English Owls have always been moderately-sized Pigeons, as Turbits have been and are, and as Jacobins have been and are; for though the Jocobin has been written of as one of the smallest Pigeons, it never was—it only, according to fancy rule, ought to be. The Owl has always been a flying Pigeon, and many Antwerps used to show a bit of the Owl frill. This, I think, is conclusive about its size, for no very small Pigeon can fly much, it is too weak. English breeders of African Owls have spoken of them to me as "sort of greenhouse birds." In a warmer country no doubt they would feel more at home in the air and on wing, so I am not surprised at their doing well in India.

Next about the term "degenerate" as applied to the African Owl, to which "Bubo" objects. I mean it in the same sense as a Short-faced Tumbler is degenerate—namely, "having declined from its natural growth" or become smaller, as the French soldier of to-day is smaller than the soldier under the first Napoleon. I did not mean "degenerate" as a term of reproach, but as meaning smaller and feebler. No one can admire the Foreign Owl more than I do, and I agree with "Bubo" thoroughly that the best colour is white; it is a fairy-like little Pigeon, and white just suits it.

Then comes the question, How about the two varieties? Well, I would say they are simply the production of two climates; the Foreign of the warm climate, the English of our colder climate. That is how I would account for the difference. I believe imported Barbs are smaller than those English-bred, and which are naturally bred in England, I mean not bred in-and-in.

The analogy between the English and Foreign Trumpeter hardly, I think, holds good, as the Foreign bird is the larger and finer, coming (climate again making the difference I imagine) from a colder country. Unfortunately the Foreign Trumpeters will not breed in England, while fortunately the African Owl will.

I think I have now noticed every point mentioned by Mr. Lyell and "Bubo," and I am truly glad that two educated and intelligent writers, learned also in the old books, and respecting their authority, have come to the front, and I welcome them heartily, and hope their pens will not be idle. We want such writers, and not writers of "pert and perky" letters, who are Pigeon-ignorant save in what some judge they approve likes.

Mentioning judges, I hope all the newer ones will read the old books, or they will lack knowledge they ought to possess, for the Pigeon fancy is no new thing, but at least one hundred and fifty years old, or indeed much older.

Reverting once more to the Owl, I hope English and African Owls will both be bred and prizes offered for each as they now are. A mixture of the two birds, to my eye, spoils both.—Wiltshire Rector.

N.B.—Looking at my copy of Girton I see it is called "The New and Complete Pigeon Fancyer." How unprincipled those eighteenth-century writers were! for the book is simply what might have been correctly termed "A Third Edition of Moore's." No doubt the writer of the Treatise and Girton both had practical fanciers to tell them much. Girton also gave (copied, no doubt) the natural history of the Pigeon, but with blunders. The two books were made to order for publishers, and on the whole they are well done; but there was no original writer between Moore and Windus of the Almond Tumbler. Hence I am only surprised that Girton made so few mistakes, but one he did make in regard to the Owl, as I have shown, and then built up an argument upon his mistake.—W. R.

CANARY-BREEDING CAGES.

Simplicity of construction in cages for this purpose is one of their chief recommendations. Decorative and emblematic design so frequently witnessed are generally the productions of mistaken but ingenious persons, who have little practical experience and still less compassionate regard for the comfort of their birds. Yet good birds demand good cages, for they are worthy of being displayed to the greatest advantage. The old breeders of the Canary distinguished as "The London Fancy" seem to have been a very painstaking class. Whatever objections may be raised to many of their arrangements, nothing can be said against their excellent breeding and flight cages. They have appreciated the importance of cleanliness, comfort, and the general healthfulness of these constructions, no doubt prompted by the difficulties encountered in breeding this remarkable but delicate bird. Such cages have been in use for thirty years, and after an annual cleaning are in every respect equal to new.

They are generally made of mahogany, and are known as "box cages," rendered very convenient by the front part being wirework, and this removeable. Such cages are so constructed that the feeding cage for weaning young birds can be placed inside or hung on at the doorway, a system to be highly commended in preference to double or compartment cages, as there are better facilities of thoroughly cleaning than can be where two or more cages are combined; and if they are sufficiently large, which adds but slightly to their expense, they can be readily converted into flight cages for moulting and storage during the winter season, a convenience for which many breeders will be thankful.

Mahogany is decidedly the most lasting and solid wood for making cages, but it has two drawbacks to its general adoption for this purpose—great weight, and expense. It fortunately happens that their requirements can be supplied equally well, and where hanging cages are employed even with advantage, by using American pine; this wood, if well selected, free from knots and cracks, and with the work neatly fitted, and every joint well glued and nailed, makes excellent cages. The glue should be used freely, so that every joint be completely closed by it, for wherever interstices exist you may expect, even with the greatest precaution, a colony of red mites.

Any close-grained well-seasoned wood may be employed, but the pine has advantages not possessed by other kinds, and when neatly stained and varnished can be made very effective. Mahogany may be employed for the removeable parts, because it is stronger and can be kept thinner and lighter for appearance.

The only ornament necessary is that the front edges of the body of the cage be stop-chamfered. The stop-chamfering may be cut in with black which adds greatly to the appearance. Should the cages be bought in the white—that is, without any colouring inside or out—you can finish them to your own taste as follows:—Carefully remove any roughness, then rub over with fine cabinet-makers' glass paper, and size the inside and out with two coats of paper size, not too strong; when dry again rub lightly down with the glass paper, and then give the inside a coating of the following paint:—

Oxide of zinc, which may be purchased at any chemist's if not obtainable at an oil and colourman's, rubbed up well into a very stiff paste with a small quantity of copal varnish, and thinned down to the consistency of ordinary paint with turpentine; this may be conveniently done on a large dish or stone slab with a thin table knife. This paint dries very quickly, and if too much varnish has not been used gives a very desirable appearance with two or three coats. It may be tinted with a small quantity of oil blue or other colour according to taste. Before laying on the last coat stop all joints and cracks with glazier's putty. This paint will not be found injurious to birds if allowed to dry for two or three days before using the cages, and they can be frequently washed without re-whitening.

The outside, except where mahogany has been used (which is preferably French-polished), can be stained any light tint and varnished with the following:—Half a pound of shellac dissolved

in a wide-mouthed bottle in one pint of methylated spirit. You have only to mix those two articles, and with an occasional shake-up the varnish will be ready for use in a few days. It dries very quickly, you can lay on two or three coats in an hour, and the cage may be used immediately. For any parts required to be painted black, a small quantity of lamp black stirred into a portion of the above varnish is excellent.

In the spring of every year, say the end of February, and again in August, or as frequently as you may consider desirable, wash your cages over well with strong salt and water, which will destroy all insect life, and give them a thorough scrubbing and rinsing in clean water: this must be done inside and out. If necessary when dry give one coat of white to the inside, and revarnish the outside. Thus you can avoid the red mite.—J. Packham.

BEE OUT-LOOK FOR 1875.

The dawn of the second quarter of the year is always interesting to humanity, at least in the northern hemisphere; and to whom is it more interesting than to the bee-keeper? for all his labours are, as it were, concentrated in the three approaching months of April, May, and June. 'Tis true that the main honey harvest is usually gathered in July, but by no means invariably so. The months of May and June frequently boast of the principal ingathering of the year. What, then, of the season of promise that is now before us? Everything is hopeful this year to all bee-keepers whose stock is vigorous, even though the spring is very late and breeding has not been advancing at a rapid rate, for the winter has been on the whole everything that could have been desired. Snows and frosts have enriched and opened the ground, preparing the way for the fertilising influence of the winds of March and the showers of April: hence I augur an abundance of saccharine matter this summer. So Hope is on the tiptoe of expectation.

We trust, then, that all earnest bee-keepers are on the alert, and have everything in order. The first thing to do, if not done already, is to put the hives in the best possible condition for ulterior work. Floor-boards should be cleansed or renewed, old comb and superfluous drone-comb should be cut away, both being replaced where possible (as in all bar-frame hives) with fresh worker comb saved from stocks which may have failed during the winter. Queenless hives should be broken up, and their population joined to a neighbouring stock. It is a wretched waste of good material to let these die-out. For the same reason all unusually weak stocks should be united to others. Let these various operations be carried out on the first balmy day when the sun is out, and let not the soothing influence of smoke be overlooked in all manipulations of hives. Success often depends upon its use.

Next have recourse to a system of continuous feeding, not in large quantities to supply inducements to the bees to store it, but just enough given on warm days to stimulate the hive into activity, and especially the mother bee, by increasing the internal heat, which feeding always produces. Take care, however, to avoid creating a strong upward current of air, which would chill the brood. For this reason close up and cease feeding at night, and by day also, when the wind is cold, especially if it blows in the direction of the entrance.

Where hives are small it is excellent policy to add ekes to them in the spring. The bees will gladly lengthen-out the combs as the queen's activity increases, and every inch added thus to the hive affords room for the rearing of many thousand bees, whose addition to the population will both furnish large swarms and increase in proportionate ratio the honey harvest of the year. Ekes added for increase of honey space later in the summer are a mistake.

Where possible, and especially in cold situations, keep the hives as warm as possible by narrowing the entrances, so as to diminish the indraught of wind, and cover them up with carpet or straw coverings to prevent loss of heat. Of course we must open the entrances as the season advances, and allow the bees as they grow in numbers every facility for speedy and easy ingress and egress, more particularly so in hot weather.

Simultaneously with the increase of the population by the addition of ekes to the hive below, space for honey-storing should be given above in supers. These should be not more than 4 or 5 inches deep at first; but they can be enlarged as they get filled by affording ekes of the exact length and breadth of the super, say 3 or more inches deep. They can be easily secured to the super (as to the hive below) by a few hooks and eyes. This method of enlarging the super is far preferable to the usual plan of introducing an entirely new super, which often puzzles the bees and delays their working, besides tending to the formation of swarms. Of course I am here supposing that honey is the principal object of the bee-keeper. It matters little whether hives of wood or of straw are used, ekes of either material can be used at pleasure.

All material necessary for the sake of working the apiary to the best advantage should be prepared at once, such as hives, supers, boards, &c. It saves a world of trouble and confusion to be prepared beforehand. Take care also to sweeten all hives, new ones especially, by exposing to the air a month before use. Many valuable swarms have been lost by inattention to this necessary rule.—B. & W.

BEE AND HONEY EXHIBITIONS OF 1875.

It is, I think certain, that there will be an annual exhibition at the Crystal Palace in the month of September. I have been told that the apiarian fête there will come off about the 20th of the month this year. I have heard that there will be a bee and honey show in Glasgow about the 8th of September, and that £40 will be offered in prizes. In connection with the fruit exhibition at the Manchester Botanical Gardens in the first week of September there will be another apiarian fête. I called there the other day, when I was told that the Society would give £25 if the bee-keepers would raise £25 more, thus making a sum of £50 to be offered as prizes.

We hear of many small places offering prizes for bees and honey in connection with floral exhibitions; but the Crystal Palace, the Manchester, and the Glasgow Shows will, we trust, do much to popularise bee-keeping.

We shall probably hear of Dundee, and Aberdeen, and perhaps Exeter following the example of the larger towns. The interest taken in bees and bee-culture is increasing very fast. As to the Manchester fête I have of late been so much engaged that I have had no time to see any of my neighbours or consult them about a schedule of prizes. As soon as one can be drawn up it will be sent to the *Journal of Horticulture*, and other publications for insertion.—A. Pettigrew.

LIGURIANS v. BLACK BEES.

I am at a loss to see any need of such a trial between Ligurians and black bees as suggested by Mr. Pettigrew. Why should not each apiarian follow his taste and keep the variety he likes best? As to the fancy for Ligurians dying out, this is quite a mistake, at present at any rate; for I am in a position to know that many hundreds of English stocks are annually ligurianised, and that this breed is increasing in both north and south very rapidly.

The results of experience with Ligurians have been so often recorded, and almost without exception favourably, that it seems to me superfluous to keep telling the same tale over and over again. The importers of Ligurian queens in London last autumn had so many orders that many remained unexecuted, and I have no doubt the demand this summer will be still greater. I never heard an instance of a bee-keeper who had adopted Ligurians to any extent afterwards abandoning them for his old friends. Mr. Pettigrew has, he says, not tried Ligurians, therefore from his own experience he is not competent to judge, and the most that can be said against them appears to be that they are better breeders but not better honey-gatherers. Hundreds of bee-keepers will affirm they are better in both respects; but admitting the first, I am at a loss to know how the other can but follow.

Mr. Pettigrew himself is a great advocate for strong stocks and rightly, as a hive with 60,000 bees is much more likely to produce a large harvest than two of 30,000 each. If, therefore, a Ligurian queen will breed three bees while a black queen is breeding two, it follows that more work will be done.

The most profitable bee-keeping in the world is probably carried on in America, where it is followed as a business by many people. There a man's harvest in honey is reckoned by tons and tens of tons. One bee-keeper last year made $30,000 by the sale of 67 tons of that sweet produce. Many bee farms muster one thousand and even two thousand stocks; and so well is the superiority of the Ligurian variety appreciated that it is generally cultivated—the importance also of never leaving a stock without a fertile queen (as is the case after the natural swarming) results in a very large business being done by dealers in supplying such bee-farmers with fertile queens ready at need.

In a number of the "National Agriculturist" now before me I find no less than twenty-eight advertisements from breeders and importers of Ligurian queens; as much as $6 being priced for fertile Ligurian queens. Business is also done in selling Ligurian bees' eggs for queen-breeding, and for this purpose the combs containing eggs are cut into strips, packed in little boxes with a number of bees to keep the eggs warm, and then dispatched far and near by mail for use in nucleus hives. I do not see why this plan should not be adopted in England as well as the distribution of ripe queen cells, although the disadvantage would occur of uncertainty as to pure impregnation. Where the would-be queen-breeder has the advantage of a Ligurian apiary near him his chance of success would be very much increased, but in my opinion even a cross-bred stock is more valuable than pure blacks.

I think bee-dealers here are wronged when it is insinuated that the praise of Ligurians are sung for the mere purpose of

extorting high prices for fancy stocks. It might be retorted that other dealers decry Liguriana as they have only black bees for sale. It is not forgotten that the very old apiarian and poet Virgil says—

"The better brood, unlike the bastard crew,
Are marked with royal streaks of shining hue."

—John Hunter, *Eaton Rise, Ealing.*

THE CANDYING OF HONEY.

The results of experiments made in America on this question which are quoted in the Journal are very interesting. In writing on crude honey some time ago it was said that it never candied. This statement is not absolutely correct, for the crude honey obtained last year in June or July candied this year in February. It was an exceedingly fine sample of pure nectar or crude honey which had been subjected to a long process of evaporation. Almost all our apiarian visitors last autumn tasted it, and said it was quite different from real honey. When it was found crystallised it was tasted, and then melted into its former liquid state. After all it was nothing but crude honey, smelling and tasting more like the nectar of flowers than real honey.

Hitherto we have not met an instance of crude honey crystallising. Now that we have seen one it is but right to withdraw the statement that it never candies. While we withdraw the statement alluded to, our views and opinions on the question of crude honey are strengthened and confirmed by the very experiment which has enabled us to see that it is possible to solidify or candy crude honey.

Everyone should know that candied honey is easily melted or liquified by heat, and is quite as good afterwards as before. The honey from some kinds of plants candies much sooner than the honey from other kinds, and the crystals of some kinds are much larger than the crystals of other kinds.—A. Pettigrew.

ITALIAN BEES.

I extract the following from the American "Bee-keepers' Magazine" for January last. The writer says:—"I have been breeding three-fourths Italian blood—viz., hybrid queen mated with Italian drones, and am much pleased with them. They are docile, industrious, and finely coloured. . . . I am not only convinced that Italians are worth more than their cost, but my old fogey neighbours are also, as all unite in ascribing my wonderful success to the breed of bees I keep." His report for the year 1874 is as follows:—"I took seventeen swarms from the pit March 17th in good order. I increased during the season to twenty-five stocks. I took 200 lbs. of fruit-blossom honey, 1500 lbs. clover, and 450 lbs. golden-rod honey, all with the extractor, and all excellent honey, except the first 50 lbs., which was thin and strong." Here is 2150 lbs. of honey from twenty-five stocks—that is, on an average, 86 lbs. per hive.—B. & W.

OUR LETTER BOX.

Bone Dust for Chickens (*A. H. M.*).—The bone dust used for manuring is quite as good as any other.

Books (*L. M. S.*).—The price of the book you mention is 3s. 6d., and is published by Blackwood & Sons.

Direction (*D. H. W. F.*).—Mrs. Cheshire, Avenue House, Avenue, Acton, Middlesex.

Guinea Pigs (*A Very Little Boy*).—They will eat all the fresh vegetables that Rabbits eat; lettuce and cabbage leaves, and slices of carrot. They are especially fond of parsley and apples.

Canary Breeding (*Blue Bell*).—We imagine you have selected a pair of Canaries to breed from, and that by this time they are paired or are pairing. If thoroughly paired place them in a roomy clean cage furnished with food, materials for building with, a nest box or basket, and all will go on well no doubt; at least we hope so. Some breeders scarce ever prepare their birds by pairing them before placing them in the breeding cage or compartments; then much squabbling and turbulence ensues until one or the other becomes subdued. In most instances, however, the temporary fits of fretfulness terminate in harmony and love. When "Greek meets Greek" and the "tug of war" appears endless, the pair must be separated. Keep your birds well at all times, but more particularly before they begin to breed, letting the pair have chopped egg, and bun or bread crumbs, and green food, which will much encourage the male bird to feed the hen. The same kind of food may be continued during breeding time, care being taken that a supply be in readiness to feed the young with when chipped. Examine carefully the eggs in the nest, when they have been sat upon for six or seven days, to see if they appear dull or of a leaden hue. Always lay hold of an egg lengthways; if the eggs appear transparent against a strong light they will be useless, and with the nest must be removed. Time will thus be gained in recruiting the hen for again going to nest. Hens vary in temperament. Some are as easy as an old shoe, and will allow you to pry about their nesting operations, and examine their eggs and young without becoming discomfited thereby; others will forsake either eggs or young if meddled with. After a hen has completed her nest and commenced to deposit therein her eggs, remove all superfluous building materials, clean and scrape the cage bottom, and after supplying it with grit sand, let the cage so remain during the sitting and chipping of the eggs, which latter will take place on the thirteenth day from the commencement of sitting. Clean the cages well out when the young are about ten days old, and again before the hen begins to sit her next lot of eggs. During building the hen would be much benefited with an occasional bath, a supply of green food, and some old crushed mortar or chalk. It is a good plan to make your birds familiar with you before breeding time, and then any little prying curiosity on your part will not so much disconcert them. Our plan is when we examine either eggs or birds to leave a sprig of fresh green food entwined in the wires at the end of the perch. This at once takes the birds' attention, and leaves the impression that your interference was for the purpose of supplying them with food. We could enlarge upon our own ideas of treatment to "Blue Bell," who stated she is a beginner, but space will not now permit, therefore we should advise her to purchase a treatise upon Canary-breeding for general plan of operations, which with her own knowledge will guide and fortify her with many of the ins and outs appertaining to Canary-breeding and keeping. We can reply to other questions in future issues.

Honey Cakes (*C. J. R.*).—Mix a quart of strained honey with ½ lb. of powdered white sugar, ½ lb. of fresh butter, and the juice of two oranges or lemons. Warm these ingredients slightly, just enough to soften the butter, and then stir the mixture very hard, adding a grated nutmeg. Mix in gradually 2 lbs. or less of sifted flour, make it into a dough just stiff enough to roll out easily, and beat it well all over with a rolling pin; then roll it out into a large sheet half an inch thick, cut it into round cakes with the top of a tumbler dipped frequently in flour, lay them in shallow tin pans slightly buttered, and bake them.

Parrot Self-plucking (*F. M.*).—It is supposed to be to allay an itching of the skin, caused by the bird having bones and other unnatural food given to it, and to the want of exercise. Fruit and other vegetable food only, no hempseed, and a shower bath of tepid water daily, are the best remedies. The water may be applied through the rose of a watering-pot. If this does not put an end to the self-plucking, have a cradle made as shown by a woodcut in our twenty-fifth volume.

REMARKS.

24th.—A rather dull day, but warmer and more pleasant than the preceding one.

25th.—A fine day throughout, and much warmer, especially towards night.

26th.—A very beautiful morning, the after part fair and warm but dull.

27th.—Very fine morning; cloudy at noon; fine afternoon, but a slight shower between 5 and 6 P.M.

28th.—Squall very early; fine morning; dull noon; then bright for two or three hours; but dull after 4 P.M.

29th.—Fine till noon, then becoming rather dull, occasional sun, but a rather dull though fair day.

30th.—Fine morning, very bright at times, and pleasant all day.

Though the wind has changed to the west, and the temperature has risen about 5° this week, its general character has been very similar to its predecessor, being dry and fair, but with only short bursts of sunshine.—G. J. Symons.

COVENT GARDEN MARKET.—March 31.

The influence of the holidays has had its effect here, the markets not being so well supplied this week, or yet so good an attendance of buyers; the trade having bought pretty freely on Saturday is no doubt the cause of their absence. Importations have also been light, and, with the exception of consignments from Paris of salading and Asparagus, offers no cause for remark.

From observations taken near London during forty-three years, the average day temperature of the week is 55.9°; and its night temperature 35.2°.

THINNING GRAPES.

MANY an amateur must have looked at his bunches of Grapes in bewilderment immediately after the flowers have fallen, when the berries are little larger than a pin's head, and so closely packed that it seems impossible to cut one away without damaging the rest, and while he looks and wonders and waits for advice, they rapidly swell to the size of a pea, and every hour the task before him becomes more difficult. Grapes swell so rapidly at first, and every day they are left unthinned takes so much away from those which are to be finally ripened, that it would be well to get a little theoretic knowledge of thinning before the time comes for actual practice.

Rules cannot be laid down for thinning perfectly every bunch of Grapes, but every large practitioner has rules—it may be unknown almost to himself—by which he invariably begins thinning, and beginning well is more than half the battle. Thinning Grapes is not at all difficult when the operator can once see clearly before him what it is that he intends doing and begins methodically to do it. On the other hand, if it is haphazard work—if he merely begins by cutting out berries where they are thickest, then leaving them for a time to see if they are likely to be too thick again, going over a bunch three or four times at intervals of several days, he will make himself a large amount of needless labour, and, after all, the bunches will not be satisfactory.

I will mention (from memory) what I consider the principal points whereby to judge a bunch of Grapes, and name them in the order of their relative importance, when it will be seen at a glance that considerably more than half depends on the time and manner of thinning.

1st, Evenness of berries as to size. 2nd, Regularity of berries as to distance apart, and whether they are just so close that they will neither crush each other nor fall about loosely when the bunch is handled. 3rd, Colour. 4th, Bloom. 5th, Size of berries. 6th, Form of bunch. Last and least, Size of bunch.

Now the 1st, 2nd, 5th, and 6th of these points (supposing the Vine to be in a healthy condition) depend entirely on the thinning. All the other points are also liable to be affected by it, the 3rd and 7th by not thinning early and sufficiently, and the 4th by rough handling.

Thinning should be done as early as possible after the berries commence swelling, which is from ten days to a fortnight after the first flower opens. By this time, if the Vines are vigorous, the branchlets which bear the berries on the upper portion of the bunch will have raised themselves so as to be at right angles with the main stem of the bunch. Supposing there is a good set, it is these branchlets I commence operations on by cutting away unflinchingly every berry from the under side of them; I mean the side nearest to the point of the bunch. Next, all undersized berries are cut out; these have not been properly fertilised, and will only disappoint if left in. The centre of the bunch as soon as it can be done is thinned severely; and in the case of Grapes for late keeping, all berries which are not likely to be visible when ripe are cut entirely out. After proceeding thus far, if the berries are still too thick, leave, in preference, those which stand out boldly and have the most direct communication with the principal stems. The berries on the upper side of the uppermost branchlets may be left closer together than they are anywhere else; it is rarely they require thinning at all beyond cutting out imperfect berries. These branchlets in the course of growth turn up round the main stem, and if they are well furnished with berries, completely hide it and give a very compact appearance to the bunch. Do not be too particular about the berries being at equal distances apart, rather look to the berry stalks. If thinned properly thus early the berries when they swell will push each other into their proper places, if the stalks which bear them are so situated as to admit of this.

The thinning of a bunch must as much as possible be all done at one operation. The eye must be able to see prospectively the full-grown berries and the position they will take. A bunch cannot be thinned properly if it is operated on three or four times at a week's interval; at the most there ought to be only an odd berry or two to take out three or four days after the first thinning. A bunch of Grapes, like an ill-fitting garment, once cut wrongly can rarely be made perfect afterwards.

The thinning of the bunches to within one or two of the required number should take place before they come into flower, or a loss of size in the berries of the remaining ones will be the result.—William Taylor.

SPRING-FLOWERING CLEMATIS.

No one who saw the small plants of this gay class of flowers which the Messrs. Veitch exhibited at South Kensington on the 17th ult. could fail to have been struck with their extreme adaptability to conservatory and other purposes of decoration. Although well enough known in some circles how admirably the Clematis will force and bloom in a small state, the general idea is undoubtedly to regard it as a summer or autumn-blooming plant alone for growing in the open air, or if grown in pots, to consider that immense plants and large houses are indispensable to bring out its beauties. That is, beyond doubt, a very prevalent idea, and many with small houses are deterred from the cultivation of the Clematis in pots on account of their supposed want of convenience. As Messrs. Veitch's, and subsequently Mr. Paul's, plants showed, they need have no such fear, for if they have room to grow a Pelargonium or an Azalea in a 6-inch pot, they have room to grow Clematis.

No plants are more easy to force nor are more beautiful in March than these. Imagine a group in 7-inch pots, the plants from 15 to 18 inches high and a foot through, and each clothed with from twelve to twenty fine blooms of the most charming colours, and what at the time can equal them? Truly, few plants can com-

pare with them, and we do not hesitate to say that they ought to be grown as forced plants in every garden where a spring display of flowers is coveted. The flowers last a long time in beauty, and the plants are admirably adapted for room-decoration, for which no plants are more effective.

To their unquestionable beauty it is pleasant to add that they are of the easiest culture, and with ordinary care the cultivator cannot fail to succeed in having a display of a most satisfying kind.

In preparing for next season's flowering small plants which have bloomed this season should be placed in any sheltered position for a few weeks' rest. They should then be pruned—that is, have the old flowering wood cut away, and be repotted in light, rich, fibrous loam, taking care to have the pots clean and well drained. They should be plunged in the open ground, and to ensure good growth mulch the pots with cow manure, and keep the plants well watered during the summer. Choose a good position exposed to the full sun in order that the wood may be well ripened. During the month of October the plants must be removed under shelter to protect them from heavy rains. They can be trained into any desired form by a few stakes or wires; this may be done any time before forcing commences. No plants are more easy and certain to force.

They will be blooming in six to eight weeks after being placed in heat. They require a light house and an ordinary temperature of 50° at night, and 70° to 80° by day according to circumstances, but a few degrees of heat more or less is of no consequence, the plants being anything but miffy and tender.

A vinery just being started would suit them well, as the plants would be in bloom before the roof became covered with foliage. Thus those who have not a regular forcing house need not deny themselves these beautiful plants. When they are in full growth a little liquid manure should be given them, which will increase the size and texture of the blooms.

The double varieties do not flower so freely as the single, but their individual blooms are massive and fine. C. Jackmanni and its allied dark varieties will force, but will not bloom quite so early as the following, which have proved to be the best forcing varieties at present in cultivation, and should be included in all collections.

Albert Victor.—Deep lavender or light mauve colour; a very free bloomer and good.

Fair Rosamond.—Blush white, with slight red bar down the centre of each petal.

Lady Londesborough.—Silver-grey, with white filaments bearing chocolate-purple anthers; a free bloomer and excellent.

Lord Londesborough.—Rich mauve, with a maroon stripe down the centre of each petal.

Miss Bateman.—White, with a cream-coloured stripe down each petal, the stamens being of a pretty chocolate red with white filaments; an excellent variety.

Mrs. S. C. Baker.—Delicate pink, changing to French white, with a claret band down each petal; very free and good.

Lucie Lemoine (double).—White, fine; far superior to Fortunei or any other white variety.

John Gould Veitch.—Beautiful soft lavender-blue, with pale-coloured stamens.

There are many other varieties, but this short list embraces the best for early blooming whether small or large plants. Not one of them can disappoint the most exacting critic of floral beauty amongst forced flowers in March and April.—W.

THE ORCHID-HUNTER IN BURMAH.—No. 2.

Before closing the observations on the different varieties of Dendrobium formosum, it may not be out of place to note that there is an unusually magnificent variety of this plant common in the Andaman Islands, where it grows on the trees in the Mangrove swamps. These islands lie in the Bay of Bengal, almost in a line with Moulmein, and having much the same climate as that place, abound in Orchids and plants almost identical with Moulmein species.

One of the most curious of all the Dendrobiums—Dendrobium revolutum—is generally found growing on the same trees and under the same circumstances as Dendrobium formosum, and therefore claims attention in this place. This plant has the stem clothed with evergreen leaves, which grow remarkably closely together up the stem on either side. Though not allied to the nigro-hirsute Dendrobiums in some respects, it should no doubt form one of this division. It differs from them in generally bearing its flowers on the sides of the stems after the manner of the deciduous Dendrobiums. It has a very remarkable mode of growth, totally unlike that of any allied species. This peculiar manner of growth may not have been noticed; it is this, that the old stem continues at its extremity to grow for years, and it is this fact that causes imported plants to present such a straggling and ugly habit. The flower of this plant also being small, it is one little esteemed by Orchid growers. If, however, having a knowledge of the peculiar habit of this plant, the horticulturist steps in and prevents the prolonged growth of the old stem by cutting the old stems back judiciously so as to encourage new growths, he very shortly changes the plant into one of the prettiest and most noticeable evergreen Orchids in the house. Under this treatment also the plant flowers more freely; and although some may still be found to object to the dullish-white colour of the flower, most people will be attracted by the great peculiarity and distinctness of its form.

The next species of nigro-hirsute Dendrobiums, and as far as the climate and circumstances under which they grow being alike, the nearest allied to those already noticed is Dendrobium hedyosmum. To see this charming Orchid growing in masses on the trees in the country near Pegu is to see a sight not easily forgot. Pegu herself has not yet recovered from the effects of war; her town and pagoda are still in a state of ruin. In the midst of all this desolation Nature has treasured up some of her richest gems, for this district not only abounds in Orchids, some of which will be noticed hereafter, but it contains forests of Butea frondosa, next to the Amherstia the most gorgeous of flowering trees, making the whole district a blaze of flower in the spring months, and the Butea is the special abode of that splendid Fern Platycerium grande, which completely covers the stems of some of these trees. As regards Dendrobium hedyosmum it is pretty widely spread throughout this district, and also in the districts lying some sixty miles from Moulmein in the interior. The plant has a very compact habit, it produces its flowers in pairs from the top of the last growth, and in very flourishing plants throws out several flowers from the sides, towards the top of the plant also. It bears pure alabaster white flowers of waxy substance, having the labellum tinged with green and yellow, and marked in the throat with very bright orange stripes. In consequence of the great substance of the flower it keeps in blossom a very long time—over two months, which makes it an especially desirable plant. It is very easy to cultivate, and there is no Dendrobium equal to it for sweetness of scent, the perfume being very like that of Wallflowers.

Dendrobium Jamesianum is the next of the nigro-hirsute Dendrobiums worthy of observation. It is more conspicuously marked with black hairs than any of the same species, with perhaps the exception of Dendrobium infundibulum. It is commonly said to come from Moulmein. Whether it grew there formerly, and now escapes observation, or whether Moulmein enjoys the credit of its coming from the interior it is difficult to say, at any rate it cannot in the present day be found anywhere near Moulmein. In the interior, Tonghoo, Thayetinyo, Siam, and Bhamo in Western China it is frequently found. It is scarcely to be excelled by any other Orchid of this class. It lasts almost as long in flower as Dendrobium hedyosmum, it has more substance than Dendrobium formosum, with flowers very nearly as large, and the brilliancy of the colour of the lower portion of the lip is very striking, and as a whole it will always be among the most favoured of its tribe. The flower is pure white, the labellum being marked with the brightest brick red, the edge of the lip is very much fringed, and there is a rough texture in the throat.

This plant is not well cultivated by all Orchid growers, the cause probably being that the plant in its native districts is accustomed during the winter to very cold nights, with the thermometer as low as 40° in the early morning, and is accustomed to heavy dews. The plants of this Orchid in our stoves are very apt to acquire a shrivelled appearance unless carefully attended to, and it is probable that they require more moisture at the roots during the resting season than the other sorts of the nigro-hirsute race of Dendrobiums.—E. S. B.

Violets.—I beg leave to publicly thank your old and worthy correspondent Mr. Smith, late of Exton, and now at Mentmore, for not only teaching me how to grow these sweetly pretty harbingers of spring, but also with supplying me with a stock of plants. For a month past we have been gathering them by the basketful, and still they come in great profusion.

I am quite sure Mr. Smith's system would be read greedily. We all know Mr. Smith can use the pen as well as the spade, and let us hope he will favour the readers of your Journal with an exposition of his mode of growing Violets.—R. Gilbert.

ROSE TREES AND FROST.

I am sorry I cannot altogether agree with Mr. Beachey about injury done by frost to Rose trees. Old wood, no doubt, may be enfeebled by encouraging the growth of young wood from the base, but it will not account for the frost killing old wood still strong and vigorous, and producing young wood from the ends of its shoots as strong as that springing from the base. Moreover, in 1860 I lost ninety-eight standards out of one hundred, where the system of pruning, consequent on their being standards, was precisely such as Mr. Beachey describes, no suckers being allowed from the base of the Briar, and the heads pruned to form symmetrical bushes.

In the case of the Maréchal Niel I referred to, the young growth at the base was quite recent, and the strength of the main stems, shoots, and branches quite unimpaired. It would be scarcely possible, I think, to see more vigorous or healthy growth, the tree having in the course of four seasons covered a wall 20 feet long and 8 feet high. The young shoot from the base sprung up at the end of August owing to a redundance of sap, but it certainly could not have impaired the strength of the main stem, which was nearly 2 inches in diameter, and many shoots on the extremities of the branches were quite as strong and thick as this succulent one at the base, and I feel confident if Mr. Beachey were to see it he would agree with me.

As to the comparative merit of the two systems of growing Roses, one of which produces quality, the other quantity, there will always be differences of opinion.

Having a fair amount of Rose trees—not to be reckoned by the thousands as some amateurs, but between seven and eight hundred—I prefer to be able to pick for my drawing-room during the Rose season from thirty to fifty really choice blooms every day fit for an exhibition table. There is no way, as a rule, one enjoys Roses so thoroughly as when cut and arranged in specimen glasses or in suitable vases, and one really good Rose is, in my opinion, worth twenty inferior ones; but, as I said before, this will always be more or less a matter of taste.

As to the question of the maturity or immaturity of shoots there seems to be also great diversity of opinion. I cannot accept the fact that young green shoots are as mature as older shoots that have stood a whole summer's sun and winter's cold, nor do I see sufficient evidence that the strong growths of two and three years have been injured sufficiently by the younger growth from the base to account for the action of the frost. I find the inner pith in the old shoots more injured than the inner pith in the young, and I find old wood injured where, owing to the strength of the shoots, no young wood had been allowed to grow from the base. That sap, like water, may be a non-conductor of heat is, no doubt, partially true, but in such a severe frost as we had last year every particle of sap would be frozen; so the question still remains, Why is the cellular tissue more injured in the old shoots than the young? I am very much obliged to Mr. Beachey for his remarks, and as I, as a general rule, quite agree with what he has at different times written in the *Journal of Horticulture*, and in his estimate of Roses, I am sorry I cannot agree with him now; and till someone else can bring some other suggestions to bear, am still inclined to believe that the effect of frost on cellular tissue is very mechanical, and that the younger wood, with softer pith, and less indurated bark, has more power of expansion, so that the cell walls are not burst by the expansion of the sap. Other plants, such as Delphinium formosum, can stand an immense amount of cold when in their young state, but which die in autumn with a much less degree of cold.

I must thank "Cornubia" for his letter, especially as he agrees with what I said under the initials "C. P. P." I think he hails from the sunny south, and not from a climate like mine, where Tea Roses are killed to the ground every winter, and Céline Forestier has to push afresh from the base nearly every year. I can, however, quite enter into his enthusiasm for the true Perpetuals—the Teas, where they can be grown. Centifolia Rosea is a very favourite Rose with Mr. George Paul, and he has sometimes shown it splendidly, but I never could feel any enthusiasm myself for it, as its beauty soon fades away under either a summer's sun, or two hours in a hot tent; the petals are much too flimsy. Etienne Levet was certainly grand last year, and I have great hopes of François Michelon, but I cannot say any new varieties I saw last year impressed me greatly.

I must acquit Mr. Radclyffe of never having recommended Prince Camille de Rohan, as I remember at one time it used to be a favourite of his; but why it was discarded for Empereur de Maroc, Baron Chaurand, Maxime de la Rocheterie, and others like these, I fail yet to understand, any more than I can understand why he refuses to see the merits of La France and Marie Baumann. I am somewhat inclined to think that Mr. Radclyffe does not see enough of other persons' Roses as well as his own, and that when once he has issued a verdict in favour of a Rose he does not like to alter it afterwards, and so Edouard Morren and Felix Genero will remain amongst his select Roses for some time to come. I agree with "Cornubia," an election such as that conducted by Mr. Hinton ought to give every amateur a good and safe guide to select from, and it surprises me that so many should still write to the *Journal of Horticulture* for lists of Roses.—C. P. Peach.

THE GREAT HORTICULTURAL SHOW AT ANTWERP.

(*From our Special Reporter.*)

The hundred and twenty-fifth Exhibition of the Royal Horticultural and Agricultural Society of Antwerp was held in that city from the 4th to the 7th of this month. The locality chosen for it was the spacious suite of buildings belonging to the Société Royale d'Harmonie, and for an indoor exhibition we never saw anything better done. There is a diversity of opinion as to whether plants look better in a large well-lighted building or in a tent; each has its advocates. And then there is the other aspect of the question—whether an exhibition confined to one large space which may be all seen at once, or one which is distributed over several apartments, is most satisfactory. No doubt the effect produced by the former is very striking when first seen, but it soon passes off; while in the latter case the interest is kept up in passing from one part to another, each furnishing its own special and varied interest. It was so in this Exhibition at Antwerp. A great hall, very much larger than St. James's Hall in London, but arranged much in the same way, with spacious galleries on either side, was filled most tastefully with groups of flowering and fine-foliaged plants, and this was the chief part of the Exhibition; but there were smaller halls and apartments, which were devoted to smaller subjects than those exhibited in the large one.

The centre of attraction was, of course, the large hall. The centre of the floor was occupied with three large groups of Azaleas, which were masses of bloom, and were grown in a hemispherical shape. They were handsome healthy plants, but there is the same objection to them that used to be urged against the large specimens grown in England, and which were so long the chief attractions at our exhibitions—that they are too stiff and artificial, and wanting the grace and freedom of plants allowed to grow more naturally. The corners of the hall were filled with large specimens of Palms, Tree Ferns, Cycads, Dracænas, and other ornamental-foliaged plants. Those who seemed to contribute most to the decoration were Madame Le Grelle d'Hanis, M. de Ghelliuck de Walles, M. Van Houtte, M. Vervaen, M. Charles Van Geert, and others. At the extreme end of the hall was a group of Camellias, the most extraordinary plants we have ever seen. They were from 18 to 24 feet high, and none of them more than 2½ feet through. They were remarkably well grown, full of health, and covered with bloom. These plants are seventy years old, and the gentleman who propagated them was present in his eightieth year to testify to the truth of this statement. They are exhibited by M. Edmond Le Grelle. The Camellias generally, of which there were numerous groups distributed over the Exhibition, were well grown.

Under the galleries we remarked some good exhibitions. Among them a wonderful collection of Aralias from Madame Le Grelle, a group of ornamental-foliaged plants from Baron Osy de Wychen; a group of Agaves, Bonaparteas, and Liliads from M. Beaucarne; and well-grown plants of Camellias from M. Jean Vervaen and M. Vuysteke. In the gallery on the right the first object which attracts attention is a pretty lot of Azalea indica, exhibited by M. de Ghelliuck, which for fine cultivation were not excelled in the Exhibition. Among the most striking were Comte de Flandre, Punctulata variegata, Eclatant, Magnifica, Charmer, and Grande Duchesse de Bade. Occupying the corner opposite there was a fine collection of thirty Hollies, fine large specimens in baskets, exhibited by M. Charles Van Geert of Antwerp, and they unanimously received the first prize, as they well deserved. Among them we observed a very pretty species called crenata, with small leaves of the size and shape of the dwarf edging Box. In the corresponding corner opposite M. Van Geert had a collection of thirty large Conifers, specimens of perfect cultivation, which

received the first prize of a framed silver-gilt medal. In a collection of variegated plants exhibited by M. Hillegeer of Beveren we observed a purple-leaved Peach, which if introduced to shrubberies would form an object of interest and produce a good effect.

Generally speaking, the Camellias were very fine well-grown plants in rude health and abundance of bloom. Where, if not in Belgium, can we expect to see such Camellias exhibited, where they form an article of such extensive commerce? Belgium is as much the home of the Camellia and Azalea as Holland is of the Hyacinth and the Tulip. Those who were most successful in the classes for Camellias were M. Ed. Le Grelle already mentioned, who received the framed gold medal, or three hundred francs, for his tall specimens; and M. Jean Vervaen of Ledeberg was second with some well-grown bushy specimens, which obtained the framed silver-gilt medal. The other successful exhibitors in the other classes were M. Beaucarne, M. Joseph De Coster, and M. Louis Van Houtte.

Azaleas, as a matter of course, we expected to see in their perfection at a Belgian show, and we were not disappointed. We have already referred to the great groups that were on the floor of the hall, and these were contributed by M. de Ghellinck de Walle of Ghent, whose splendid group of thirty carried off the first prize of the framed gold medal, value 400f.; and the second prize of a gold medal of 200f. value was awarded to M. Jean Vervaene. M. de Ghellinck was again successful in the collections of fifteen plants, and obtained the gold medal value 200f., while M. Beaucarne was second. For the finest specimen M. de Ghellinck was again successful.

Rhododendrons were well represented. Orchids were very sparingly exhibited. Amaryllises were shown by M. Van Houtte of Ghent, M. Van der Linden of Antwerp, M. Louis Eeckhante of St. Denis-Westrem. M. Van Houtte took the first place in every instance, but we could not but remark that the style of flowers cultivated in Belgium would not find favour with us in England, in consequence of their narrow-pointed petals, which contrast unfavourably with the fine, stout, flat, and broad petals of our English strains—those sent out by Messrs. Veitch and Mr. B. S. Williams for instance.

Hyacinths and Tulips were much fewer in number than one might have anticipated. The season here as well as with us is unusually late, and no doubt the fewness may be attributable to this cause. But it did not prevent Messrs. Krelage & Son of Haarlem coming forward with a very fine exhibition of a collection of one hundred varieties. They were in good condition, with long, stout, densely-bloomed spikes, and worthily received the gold medal or 200f. For a collection of fifty Tulips, single flowers, Messrs. Krelage were again first. Cyclamens were well represented by Madame Jean Everaerts of Antwerp, and M. Van Houtte. The exhibition of the former was a fine collection of twenty-five varieties of Cyclamen persicum, which reminded one of the same plants as are exhibited at South Kensington. They were examples of superior cultivation and worthily received (*à l'unanimité*), the first prize of a silver-gilt medal. M. Van Houtte's collection comprised principally hardy species, such as Atkinsii, ibericum, hybridum, carneum, &c.

Forced Roses in pots were here, as they always are at our own exhibitions, objects of attraction and admiration. The great gold medal offered by the Queen was very appropriately given for the queen of flowers, and the successful candidate was M. A. A. Peeters, St. Gelles, near Brussels. These were all standards and shown in a close group forming a mass of green foliage with the flowers standing well above it. Being standards they came up well to the eye. The second honour fell to Madame Jean Everserts for a lot of remarkably well-grown plants, which for vigour and luxuriance of foliage surpassed all the other collections. These were dwarf plants of large size on their own roots, well bloomed, and in greater variety of colour than the last-named collection.

Palms were well represented, and the gold medal or 500f. for the collection of twenty was carried off by Madame Le Grelle D'Hanis, and they were certainly very fine. Madame Le Grelle was also successful in obtaining the large gold medal offered by the King for a collection of twenty Marantas, which filled the whole of the extreme end of the smaller hall. For ten ornamental plants of different kinds Madame Le Grelle was again successful in carrying off the gold medal, and Baron Nottebohm of Antwerp was second, both having obtained their awards as the prize list says *par acclamation*.

In speaking of the gallery on the right we omitted to notice a very rich collection of Ivies in pots shown by M. Charles Van Geert, which received the silver gilt medal *par unanimité*.

The most charming plant in the whole Exhibition, and that which attracted most attention as a novelty, was a seedling Bertolonia exhibited by M. Van Houtte of Ghent, having in its venation one of the most beautiful pieces of colouring to be met with in the vegetable kingdom. The leaves of the plants, which are shown in fine condition under bell glasses, are 6 to 7 inches long, and about half as broad as they are long, of a dark brownish-green ground, relieved with veins of bright aniline purplish pink. This is sure to become a popular plant in England.

It would be impossible, or at least not profitable to our readers, for us to notice the exhibitions that were made in every class. We have cursorily gone over the leading collections and given a general sketch of the Exhibition. We will now conclude by noticing a collection which attracted much attention in the Exhibition, which was brought by our own enterprising countryman Mr. B. S. Williams of Upper Holloway. This occupied the whole of one division on the side of the smaller hall, and consisted chiefly of new and rare plants in bloom. They were not entered for competition, and consequently no prize was awarded, yet Mr. Williams had the satisfaction of knowing from every evidence that his contribution to the Show was highly valued.

The gold medals of honour of the value of 300f. each, one for the exhibitor living within and the other for the exhibitor living without the Arrondissement of Antwerp who had contributed most to the embellishment of the Exhibition, were respectively awarded to Madame Le Grelle D'Hanis and to M. Louis Van Houtte.

After the opening of the Exhibition a grand banquet was given to the Jury in the hall of the Flemish Theatre. The chair was occupied by the excellent President of the Society, Baron de Caters, whose father was president before him. On his right were the Burgomaster of Antwerp, Dr. Hogg, the Burgomaster of Ghent, M. Krelage, M. Kegeljan, and Professor Morren. On his left were M. de Cannart d'Hamale, M. Ronnberg, M. de Ghellinck de Walle, Vicomte de Forceville, M. Alph. de Cock. Among the guests were representatives of all the gardening nationalties, such as Mr. B. S. Williams of London; Vilmorin & Thibaut of Paris; Dr. Mulder, Mr. Van Lennep, and Mr. Willink from Holland. This was one of those sumptuous entertainments with which we have been made familiar by visits to Ghent and to Brussels; and we can only say that Belgian hospitality appears to be universal, for the reception we met with at Antwerp was a repetition of those which had already won our hearts years ago, and which have caused them to beat responsively in sympathy with the Belgian people.

ROYAL HORTICULTURAL SOCIETY.

April 7th.

No fruit was submitted for judgment in the Council-room on this occasion.

Floral Committee.—R. B. Postans, Esq., in the chair. Not extensive but interesting groups of plants were staged at this meeting. Messrs. Veitch sent a very attractive collection, comprising three distinct Crotons, which had been received from A. H. C. Macaffee, Esq., of Sidney—viz., C. Disraeli, with foliage of great substance, and reminding one by its bold, rigid, and curiously-divided leaves of the Platyceriums. In colour it is deep green with yellow bands. It received a first-class certificate. C. Lord Cairns is similar in colour, and C. variabilis exhibits a mixture of pink, green, and buff. The same firm sent Anthurium violaceum, a dwarf variety with good dark green foliage and clusters of berries, arranged after the manner of a miniature head of Maize, but pendant, and of a delicate lavender violet colour. It received a botanical commendation. Spathiphyllum Wallisii, an Anthurium-like plant of vigorous habit, and showing several spathes, one of which is expanded; it is ivory white in colour. Croton appendiculatum, a remarkable green variety of dwarf habit; from the extremity of each leaf is subtended, by a delicate filament of 1 to 2 inches in length, another or sub-leaf, which renders the plant very distinct and curious. Croton tortile, a spiral-foliaged form, of great substance and of dark metallic hue. Dracæna Hendersoni, a plant having the elegant habit of D. Cooperii, with leaves of a singular yet not irregular mixture of colours—white, pink, green, and brown being closely blended. Interesting Droseras—viz., D. dichotoma and D. spathulata (first-class certificate), Darlingtonia californica, Cephalotus follicularis, and Sarracenias, purpurea, psittacina (vote of thanks), and Stevensii; also Drosophyllum lusitanicum, which had a botanical commendation. These were in remarkably good order, and were exceedingly curious and attractive. Messrs. Veitch also sent Camellia Mathntians rosea, a very free bloomer and good; and Hyacinth e'na (first-class certificate). This is a semi-double variety of fine substance of petal and of a glowing salmon pink colour. It is very bright, and promises to hold high rank amongst the best of its class.

Mr. Bull sent a plant of Crinum brachymena with two spikes surmounted with a dozen flowers, a small Odontoglossum Roezlii, Dracænas insignis (dark), and candida, which has a large proportion of ivory white in its foliage—both these had first-class certificates awarded; they are distinct in colour, excellent in habit, and stout in texture of foliage. Mr. Bull also sent a small plant of the curious Masdevallia amabilis.

Mr. B. S. Williams sent a plant of the graceful Palm Geonoma gracilis; a plant also of the prickly-stemmed Palm, Martinezia erosa—both had first-class certificates; also a nice Orchid,

Warscewiczella discolor, with four very richly coloured flowers; Eurycles Cunninghami, resembling a miniature Crinum, it had a stem 18 inches high surmounted with a corona of white Narcissus-like flowers; and Pteris Williamsi, a distinct Fern of robust habit with two shades of green in the fronds.

Paul & Son, Cheshunt, had a standard plant with five blooms of the fine Rose Hippolyte Jamain; also a box of cut Roses, of which the best were Annie Laxton, Etienne Levet, and Captain Christy. A standard plant of Comte de Sarenyi was also exhibited. It is a Rose of the type of Marguerite de St. Amand.

From Mr. Perkins, the Gardens, Thornham Hall, came a box of splendid blooms of Maréchal Niel, and received a vote of thanks.

A basket of very fine Primula sinensis, Fern-leaved, of robust growth and deep carmine blooms, was sent by Mr. Eckford, Coleshill Gardens, Highworth, who sent also finely-laced blooms of Polyanthus; a vote of thanks was awarded.

Mr. Dean contributed a very showy and attractive group of hardy spring-flowering plants, comprising a fine variety of Aubrietia with deep violet flowers, named A. Eyrei; Pansies, Yellow Boy and White Swan, a great variety of Primroses, and a charming margin of Myosotis dissitiflora. Most of these Primroses are admirably adapted for frame culture, and, some of them being distinct, are spring bedding plants. The group consisted of single and double varieties, both selfs and laced, and ranged in colour from pure white to a deep blood crimson. They well merited the vote of thanks which was awarded.

G. F. Wilson, Esq., F.R.S., sent plants of Alpine Primulas—P. pulcherrima, a beautiful variety, like a globular and gigantic truss of Verbena on an exceedingly stout stem; and P. viscosa, of a closer habit of growth.

A splendid plant of Dendrobium nobile, 4 feet high and through, carrying many hundreds of fine blooms and an abundance of healthy foliage, was exhibited by Mr. F. Moore, gardener to W. C. Pickeregill, Esq., Blinden Hall, Bixley, and had worthily attached a cultural commendation; also an equally splendid plant of Dendrobium densiflorum, with twenty-four fine spikes, from Mr. J. Staples, gardener to Mrs. Candy, Chipstead Place, Sevenoaks, had also a cultural commendation. Both these specimens bore unmistakeable impress of excellent culture. From the Society's gardens were densely-bloomed plants in pots of the small light Clematis C. montana.

MY HOME PLOT.

Mine is emphatically a cottage garden, and as that is also one of the titles of your paper, I thought I might venture to place mine and yours together, as I have done before. But while I freely admit that my garden has often been benefited by yours, I am not at all certain that I can confer any benefit on you in return. I will not, however, aim so high as that, but will think rather of (my and your friends) people of my own order, who have little plots of their own, and who derive a great deal of pleasure, if not much profit, from their essays at gardening.

I have a flower plot and a vegetable plot, a few window plants, a handlight, and a small frame. My windows are always at this season crowded with plants which I have managed to keep through the winter. My frame is filled mostly with Calceolarias, the cuttings of which I put-in in the autumn, with a few plants of Pentstemons, Antirrhinums, and young Carnations which are not safe to leave out all winter. These are always safe under a little glass, while they can be planted-out early, and always do well in my garden.

Now all these I plant out at once—in fact, this sets at liberty my frame, and my overcrowded windows are thinned out by filling it with a portion of the plants. This hardens them—the Geraniums and Fuchsias—either for planting out or for flowering in pots. If I have more than my frame will hold I place some under the shelter of a wall and cover them at nights, and also shade them for the first few days from bright sun. That I find very necessary, for as their leaves are tender, the sun has much the same effect on them as frost when they are first turned out, so to make sure I shade from frost and sun too. It is surprising how nicely these plants come on. They do not look bright at the first, but they grow, if slowly, yet surely, and in the end always do better than the plants that are left too long, and so are drawn, in the windows.

At this time of the year I always shake my window plants out of their pots. Of course I do the work very carefully. My reason is this—the soil has become hard by repeated waterings, and besides it is exhausted, as some of the plants have been feeding on it the most of last summer. I give them fresh soil—food. I never put them in larger pots at this season, but rather repot them in smaller pots, as I find them do better. I have these pots clean, especially inside, as I am sure it is beneficial to the plants. I should as soon think of eating my dinner off a dirty plate as giving a plant a dirty pot, so I always wash the pots and have them dry before using. I drain my pots well. My neighbours are generally careless on this point, and thereby make a great mistake. Draining is the beginning—the alphabet of potting. If it is not learnt properly the next steps are all wrong together, and the work goes for very little and must be done over again before success can be reached. Therefore by way of a good beginning, as I said before, drain well. If I have not a piece of broken pot I obtain a flat oyster shell and lay it over the hole. I break others and lay them nicely over in layers, and break some bones fine and put over the shells. For a 4-inch pot I have an inch of drainage, and for a 6-inch pot nearly 2 inches, and all put in systematically. Before I put in the soil I cover the drainage with tree leaves or moss—anything to keep the soil from choking it, for it is of no use draining and spoiling it the next moment as—I had almost said most people do, but of course I do not mean good gardeners.

I am not so particular as to soil as some people, so long as it is in a nice state as to moisture—that is, neither too wet nor too dry. I find the surface scraped off my garden (if I have no better loam) mixed with pounded shells, and cocoa-nut fibre, in the place of leaf mould, answer well for almost all plants; but I have an opinion that careful drainage, potting, and watering makes up for the lack of dainty mixtures. I mean the soil is often blamed when the real fault is in the management. In potting I take nearly all the old soil from my plants, and pot them in the fresh, pressing it into the pots rather firmly, as light potting I have long since proved to be faulty. I never fill my pots level full; that would be a great mistake, but always allow fully an inch from the surface of the soil to the rim of the pot to hold water. For a time I water carefully, for until plants have active leaves they require to be slightly watered. Now, with this care the plants root into the new soil freely, and forthwith begin to make healthy steady growth. I always go over all my plants at this season, and give a general potting as above described, and I feel the benefit of the work throughout the whole season. Those that are to be kept in pots flourish well, and those that are to be planted-out in six weeks' time always establish themselves more quickly and grow much better than if the old winter's soil had been left clinging round their roots after the manner of balls of plaster or cement.

I may now leave my plants, being sure that they are all right, and attend to sowing a few seeds for my flower garden. I like raising these in pots. For seeds I drain my pots extra well, and fill with light rich soil made very fine and smooth on the surface. I then before, not after, sowing the seeds water thoroughly. I sow a pot of Beet for dark foliage (if sown out of doors the sparrows eat it); this is a fine contrast to the Calceolarias. If my Musk is dead I sow a pot of seed, and raise hundreds more. I always plant this in my garden; it does so well, and is so sweet. I sow a pot of Golden Feather, and have plenty of plants for edging. I also sow Asters—the Victoria and Dwarf Chrysanthemum-flowered, Ten-week Stocks, Marigolds, Zinnias, Indian Pinks, a little Ice Plant, and Phlox Drummondi. For tall plants I sow the Variegated Maize. These seed pots I often keep in the window until the soil lifts, not a moment longer; they are then placed in the frame. I always shade the surface of the pots until the seedlings appear, which prevents drying, as if the soil is dry even for an hour or two the seedlings go off. I cover all the seeds their own thickness with soil and no more, and by always keeping moist, and yet never really wet, I seldom fail, except I sow too thickly. Too thick sowing is one of the most common errors of the day. Plants are seldom spoiled by being too thin in the pots, but are frequently ruined by close crowding in their young state.

Now, by sowing at the present time the plants are ready to prick-out just as the weather is warm enough to receive them outdoors, and my frame is at liberty again, and the plants are in much better order than if they had been sown earlier and made tender by longer nursing under glass.

But I must glance at the vegetable plot. I sow now dwarf Peas in rows 15 inches apart, and Beck's Gem Beans the same. I sow a little seed of Paris White Cos and Drumhead Cabbage Lettuce, a little Early York Cabbage (it is delicious in autumn), Walcheren Cauliflower, Snow's Winter Broccoli, Brussels Sprouts, Savoys, and Cottager's Kale. I sow all these in drills very thinly—more thinly, in fact, than do many gardeners, and long experience tells me I am right. I also plant my early

Potatoes at this time in kiln-dust; no other manure is so good for them. As a background of green I plant Jerusalem Artichokes, and have a useful vegetable in winter.

Under my handlight I now sow a pinch of Celery seed, digging the ground out 6 inches deep and filling with old mouldy manure. In this I sow the seed very thinly, and I know of no better way of raising a few sturdy plants. Preferring dwarf sorts I grow Turner's Incomparable White, and Hood's Dwarf Red as the best suited to my small garden.

I should say I cover my palings with Nasturtiums and Sweet Peas by sowing the seed now. I also have Gourds, Marrows, Canary plants, Convolvuluses, and Scarlet Runners for the same purpose, but seldom sow them until the 1st of May, or late frosts ruin my plants.

This is in some measure how I proceed in April. If my simple plan can be of use to others like myself who have home plots which they cherish and try to make pleasant I shall not have written in vain, but shall feel to have made a slight return—as I have often wished—for the many hints and advantages I have derived from your long-familiar pages, and their ever-growing attractions.—J. W. C., *Vine Cottage, N.W.*

NOVELTIES IN THE ROYAL GARDENS, KEW.

Amongst the Orchids the new Cypripedium Argus of Messrs. Veitch is in flower, it is a beautiful kind and finely spotted. C. Hookeræ is extremely pretty; the flowers vary in colour, and it is observed that with the finest-marked foliage come the worst flowers, and *vice versâ*. The rare C. biflorum is also in bloom. Cœlogyne flaccida is very attractive; the flowers are numerous, and creamy white or pale yellow, except the labellum, which is tinged with orange and marked with brown lines. Here is a very dark and fine form of Lycaste Skinneri, the darkest ever seen by several Orchid cultivators. Dendrobium superbum, sometimes known as D. macrophyllum, is very handsome in baskets. It is a splendid plant for exhibition, producing rose-coloured flowers 4 inches across in two rows, along stems 2 feet long. Angræcum pertusum is extremely curious and pretty; the white flowers are densely set on the stalk, looking down which, the several parts are seen in exact lines. A plant of Phalænopsis Schilleriana has a fine panicle, and another bears one of less size.

Saxifraga Stracheyi is flowering on the rockwork. It has been cultivated in the Royal Gardens for the last four and twenty years, but is not, however, widely known in commerce. It comes near S. ligulata, and is, perhaps, a form of that plant, though quite distinct and desirable from a horticultural point of view. It is a native of the Himalaya Mountains.

OUR BORDER FLOWERS—FRANCOAS.

Though introduced many years ago this family of plants has not been brought into that general cultivation which its merits as a border flower deserve. We have no representative of our own, but are indebted to Chili for what we possess.

The varieties vary little in appearance, but their sowthistle-like leaves have a rather pleasing effect. They are easily cultivated, but sometimes die off unexpectedly, whether it is from some enemy at the base of the leaves or not I am unable to say. To keep up the supply they should be frequently renewed by division after flowering or from seed. They are a beautiful race of plants and ought to be in all collections. They are not particular as to soil, but to see them at their best they should have liberal treatment.

I find them do well in a mixture of good sandy loam, a little peat, and well decomposed dung and coarse sand well incorporated with the soil of the border, which is broken up to the depth of 18 or 20 inches. They require thorough drainage, as stagnation from water is fatal to them. Being of slender habit they require staking to prevent them from being broken by the wind. They continue in bloom for a long time. We only have some four or five kinds enumerated, and variation in colour appears to be the only distinguishing feature, yet few as they are I am inclined to think that some of them only exist on paper.

Francoa sonchifolia is the most commonly met with, and that is but seldom seen. A good plant in bloom is a very pleasing object. F. ramosum is also very scarce; F. appendiculata is a very desirable border flower and ought to be more generally cultivated. It is well worth careful tending and continues long in bloom. There is said to be a white variety of the above which must be an acquisition to this small group, but I have not seen it; perhaps some of the readers of our Journal could give us information respecting it.—Veritas.

COCKSCOMBS.

My object in writing is to direct attention to what I consider a very fine strain of the dwarf crimson Cockscomb which I had last year in McLachlan's Glasgow Prize. I thought I had one of the finest strains of the dwarf crimson extant, but this excels it. It is said to be a cross between an American variety and the old Scotch kind, and is the finest dwarf crimson Cockscomb I have grown or seen. The plant is very sturdy, the foliage ample, the leaves having great substance. The combs are fine, symmetrical, half-globe heads, the lobes gracefully curving to the stem. There is no disposition to flatness or straight tops, and the stem of the plant is as round as a Bamboo, which is a great point gained, many plants of some strains of the Cockscombs having stems as flat as a malformed Asparagus head. The outline is smooth, and the colour bright velvety crimson. The flowers proper are not numerous. If seed be wanted the flowers must of course be left; and yet for fine heads and to continue long in beauty the less flowers retained the better.

The advent of this variety will give us, it is anticipated, equally fine forms of other colours; and who will be the first to raise a "striata," a crimson one with a central stripe of yellow across the comb, or a yellow one with a crimson stripe? Collections offered in six colours are generally a delusion, and as ugly as anything for a Cockscomb well can be. They are not worthy any attention, a majority having crooked split combs and flat stems.

A word as to culture. The seed may be sown early in April. To grow a good comb about twelve weeks is necessary. Full-sized combs will keep in good condition six to eight weeks. I have had them three months in good order in a cool house. Damp is injurious, and they keep best in a dry and cool atmosphere, but not below 50° at night. In a room I have had them for weeks, but moss placed on the surface of the pots and watered heavily will rot the stem, and the saturated soil will kill the roots and the heads will fall over.

Sow thinly in light rich loam, and place in a gentle hotbed, and keep near the glass and moist, but avoid heavy waterings. The "gentle hotbed" may mean anything; therefore to be explicit bottom heat 75° to 80°, top heat 65° at night, 70° to 75° by day without sun, and 85° or 90° with sun and air. Pot-off singly when the plants have two or three leaves in addition to the seed leaves and return to the hotbed, shading from bright sun for a few days. If bright and hot, sprinkle overhead every afternoon at closing time, and have the leaves dry when the sun shines powerfully upon them; or if not, shade slightly until dry, or they may become scorched and spotted. Shift into larger pots, small shifts at a time; and as there is no need to wait until the combs are formed with Glasgow Prize, they may be shifted onward into larger-sized pots as the pots fill with roots, 8-inch or 9-inch pots being the largest size that need be employed, whilst for general purposes 6 or 7-inch are most desirable. At each potting the plants may be sunk a little lower in the soil. This, however, is not desirable if the plants are not leggy; and if they are, throw them away, for a leggy plant is not worthy of room. To look well the height of the plant should be about that of one-half the measurement over the comb from tip to tip, or the same height as the comb is in breadth. The last potting should be given when the combs are clear of the leaves.

Water carefully after each potting, and yet on no account allow the plants to become dry so as to cause flagging: first make sure that they really require water, and then apply it thoroughly. After the last potting water with weak liquid manure, and turn the plants round if they are growing crookedly, placing opposite sides to the light. After May they succeed admirably in a cold frame, which, by closing early and admitting air moderately, may be converted into a moist stove—one admirably suited to this class of plants.

A suitable compost for these plants is turfy loam about six months laid up, with a fourth of old cowdung or well-rotted manure added. It should be chopped up fine, not sifted, be well incorporated, and have moderate drainage provided.—G. Abbey.

Cologne International Horticultural Exhibition.—We are requested to state that the ground allotted for planting shrubs for this Exhibition is now at the disposal of intending

exhibitors, who can at once commence to make use of it. No charge will be made for space.

THE BOUQUET, AND HOW IT IS MADE.

It has been an object of curiosity to many how such an arrangement is effected. I will inform them. Procure a quantity of the finest wire (copper preferred), such as is used in making artificial flowers. With this the bouquet should be tied; no string or matting is required. The wire should be kept in a coil for tying, but some portion of it should be cut into lengths of about 6 inches.

The following flowers if well arranged have a good effect. The centre a double white Camellia, the florets of a good double pink Geranium, and Stephanotis floribunda, and double blue Violet or Forget-me-not; these arranged in concentric circles round the centre, with a few fronds of the Maiden-hair Fern regularly arranged between them, with a few of the fronds placed round the outer edge projecting about 2 inches, to act as guard to the other flowers, and about 3 inches of lace paper, or, as it is better known with us gardeners, as bouquet paper.

In making the bouquet one end of the coil wire is fixed to the stalk of the centre flower, and every single flower which is added is secured by a twist of the wire. A little moss should be placed just where the wire is bound round to prevent cutting the stalk. To supply the want of a long stalk the 6-inch lengths of wires are twisted round the short stalk of the flowers and bent downwards to serve in place of stalks. By the use of the wire not nearly so many flowers are required, and they will have a much lighter appearance and can be arranged in their places much more regularly than if large trusses are used, which always look stiff and heavy.

I have often remarked to my fellow gardeners that this branch of our profession does not obtain the attention that is due to it, inasmuch as that the prizes are small and not paying for the time, trouble, and expense. This is not all my complaint. A great many are shut out from competing, not because they have not the good taste to arrange a bouquet, but because they have not a supply of choice flowers, such as Orchids and other stove-blooming plants. I have watched with a great amount of interest, and found that the prizes are nine times out of ten taken with that bouquet which has the choicest of flowers. I think if the committees of flower shows were to be a little more liberal in this class of competition and divide the prizes into two classes—say prizes for the best hand bouquet of choice flowers, and prizes for the best arranged bouquet—this would open the door to many that have hitherto been shut out.—J. H., *Gardener to the Lady C. Legge.*

TRANSPLANTING LARGE TREES.

The moving and transplanting of large trees and shrubs is one of those matters which every now and then come before the horticultural world as some new invention is brought out to effect the object; but a much more useful purpose is served by correspondents like your ingenious one "A. M." from Essex, who accomplishes his purpose without the aid of those costly contrivances called tree-lifting machines, but merely applies such homely materials as are generally met with in most places where works of a moderate kind are going on. His description of the mode of tree-moving cannot fail to be understood by all who read it, and I strongly recommend it to the attention of those who have large trees to transplant. Having had experience in this work, I also give the mode that I adopted, which, like that of "A. M.," is also homely; indeed, my plan and his are much alike, differing only in some details which when explained will enable the next operator, perhaps, to glean assistance that may be serviceable in his own case.

First of all I may observe that I am not in general an advocate for removing large trees, but there are times when it is advisable to do so. One of the most difficult of these that I had to operate upon was an Araucaria about 23 feet high, and branched to the ground, but growing near another tree a greater favourite than itself. It was decided to transplant it, and towards the end of the dry summer of 1868 a trench, about 10 inches or a foot wide and about 2 feet deep, was dug round it at the distance of somewhat over 5 feet from the collar of the tree, leaving the tree standing on a circle of about 11 feet or more in diameter. This ditch was left open, contrary to the usual practice, which is to partly fill-in with loose leaves, or something that will tempt fresh roots into it; but as the circle was larger than is often the case with trees about to be removed, we thought the portion of earth left sufficient for it to exist upon until the time came for its removal. This was delayed until the beginning of October, 1872.

The site to which it was intended to remove it to being exposed to south-west winds, our first duty was to adopt means to secure it in an upright position while travelling, and more especially when it arrived at its destination. Now as everyone is aware, an Araucaria in a healthy state is an awkward thing to handle, baffling even the active monkey, it required some little tact and not a few scratches to accomplish our purpose. At the proper height upwards we fixed a wooden collar round the tree formed of several pieces of wood about the length that reached from one tier of branches and another. To this collar was fixed four strong wires of the kind used for strained wire fences, and these acted as gye or stay ties during the travelling of the tree, and as permanent braces when it was fixed in its place. This done, and the lower branches being tied up the same as "A. M." recommends, we next cut away a portion of the ground on the side it had to travel, and also on the opposite one, deepening sufficiently to be able to undermine the bole of the tree from both sides. Eventually a tunnel was made, and as soon as it was possible to pass a plank through it was done, and some litter being put upon, it was pressed upwards against the bottom of the ball. Earth was rammed tightly underneath it so as to keep it in its place until another plank could be put in, which was treated the same, and so on until the tree was completely isolated from the surrounding ground without any movement whatever in itself. The planks were simply builders' strong scaffold planks, and care was taken in placing them to allow about half an inch space or more between each, so that when the whole were in their places a stout piece of oak timber was laid across them on the side the tree had to travel, and the planks were tied to this cross piece with stout wire. A loop of the same wire two or three strands thick was next worked round the cross piece, and the mass was now in readiness to move, the ground being cut in a convenient slope for the purpose.

We had no rollers under the mass to begin with, but we had strong tackle in the shape of a very strong rope and a set of four-sheaved pulley blocks; and there fortunately was a tree to fix the block to as a beginning. With a strong pull the tree was moved, and we then had rollers put under the ball, and when once it was fairly out of the hole and upon these rollers it moved with much more ease. The distance it had to travel was upwards of 200 yards, and as the ground was moderately dry and firm, we did without planks, except in a few places. We used the pulley-and-block plan the whole way, a sort of crowbar forced into the ground, with a man to hold it, answering the purpose of an anchor to secure the block to. The movement as a whole was not a tedious one.

The hole for its permanent abode being prepared the tree was drawn into it, and the wire-fastening of the planks to the cross-piece being undone they were drawn out one at a time without disturbing the ball, which settled itself into its position. The wire braces that were fastened near the top of the tree to keep it in its place were firmly secured to the ground, nothing more was to be done but to fill-in the soil. Favourable weather succeeded, and the tree looks as well now as it did at the time it was moved.

The check given to the tree by digging around it four years before it was removed had a good deal to do with its after-success, added to which was the mild but wet winter which followed that operation; while not the least important item was the fact that the heavy mass was settled into its new place with little damage, there not being a crack in it. I ought also to have stated that a fastening around the collar of the tree was made to the cross-piece that bound the planks together at the first, otherwise I am not sure but the planks might have drawn from underneath it at the first start, which was necessarily up an incline, when drawing the tree out of the hole.

In giving the above details about transplanting large trees, I may add that notwithstanding the success above alluded to, I would, as a rule, much rather plant small trees, and, excepting in very special cases, the smaller the better, provided that attention is paid them for a year or two afterwards to prevent weeds and other rough herbage overtopping them. It is but seldom old trees that have been transplanted look healthy and well; perhaps the best example I can at present call to memory are the large deciduous trees that form the boundary of Hyde Park, London, adjoining Park

Lane. These trees do the planter great credit. Tree-lifting machines taken at their best are simply remarkable for their mechanical powers, and as such are capable of removing very great weights, regardless of the injury to the roots of the trees operated upon.

The removal of large trees has been less popular of late than it used to be, yet I trust I have said enough to make it understood that a very large specimen may be removed with very homely materials. Small trees will always repay the planter in a better way than large trees, and the chances are that at the end of ten or a dozen years the smaller trees will have overtaken those which were of great size when removed. It is well, however to know how large trees may be successfully removed when such special work is required to be done.—John Robson.

CAPTAIN COOK'S OR KERGUELEN LAND CABBAGE (Pringlea antiscorbutica).

In the interesting despatch from Captain Fairfax, of H.M.S. "Volage" (dated from Kerguelen Island, or as Captain Cook happily termed it, the Isle of Desolation), among other items there is one of some horticultural interest. It is this, "the Kerguelen Cabbage, which grows in great abundance close to the sea, is issued to the men several times a-week." Many of our horticultural friends doubtless stood up from the perusal of the despatch with their curiosity somewhat on edge to know something more of the Cabbage which merited from Captain Fairfax this specific and honourable mention, and which moreover as yet finds no place among the varieties enumerated in the exhaustive lists of the fattest of spring catalogues. In view of the foregoing, and the fact that (thanks to the "Challenger" Expedition) living plants of this most interesting of Cabbages are now amongst us, a few words regarding this curious plant may not be unacceptable to our readers. A century or so has elapsed since Captain Cook touched at Kerguelen Island, which had been discovered by a Frenchman of that name in 1772. By reason of its unmitigatedly desolate and inhospitable aspect Captain Cook would have called it the Isle of Desolation, but did not wish to rob Mr. Kerguelen of the honour. On approaching these desolate shores not a single tree or shrub, nor the least sign of any such met the eye of the navigator, but at some short distance there was some appearance of verdure. With respect to this, Mr. Anderson, who accompanied Captain Cook as surgeon and naturalist, wrote, "The verdure which appears when at a little distance from the shore would flatter one with the expectation of meeting with some herbage, but in this we were much deceived, for on landing it was found that this lively colour was occasioned only by one small plant, not unlike some sorts of Saxifrage, which grows in large spreading tufts up the hills." Mr. Anderson then introduces our plant on the scene. "There is," he says, "another plant plentifully scattered about the boggy declivities, which grows near the height of 2 feet, and not much unlike a small Cabbage when it has shot into seeds; the leaves about the roots are numerous, large and rounded, narrower at the base, and ending in a small point. Those on the stalks are much smaller, oblong and pointed. The stalks, often three or four, all rise separately from the root, and send up long cylindrical heads of small flowers. It has not only the appearance, but the acrid, watery taste of the antiscorbutic plants, and yet differs materially from the whole tribe; so that we look on it as a production extremely peculiar to the place. We eat it frequently raw, and found it almost like New Zealand Scurvy Grass; but it seemed to acquire a rank flavour by being boiled, which, however, some of our people did not perceive, and esteem it good." He then adds—"If it could be introduced into our kitchen gardens, it would in all probability improve so far by cultivation as to be an excellent pot herb." We give this extract in full, because it is the earliest description of the plant that we know of, as also an account of botanical acumen which it shows the writer of it to have possessed. The practical suggestion with which it closes remains yet to be put to the test; for until the naturalists attached to the "Challenger" Expedition succeeded in procuring and sending home seeds of it last year, no previous scientific visit to the Isle of Desolation was paid at a time when seed was procurable.

When during the Antarctic voyage of the "Erebus" and "Terror," the island was visited by Dr. Hooker, it was at a season when, as he tells us, he failed in seeing the flowers except in a broken and fragmentary form. In that magnificent work, his "Botany of the Antarctic Voyage," he alludes to this plant as being perhaps the "most interesting" procured during the whole voyage, "growing as it does upon an island the remotest of any from a continent, and yielding, besides this esculent, only seventeen other flowering plants." Dr. Hooker describes it as having "a long, stout rhizome, very similar to that of the Horseradish, and not altogether unlike that of the common Cabbage, which is, however, annual, while both Pringlea and Horseradish are perennial." In the form of the head of leaves to the common Cabbage Dr. Hooker says the resemblance is "most striking," and so is "the use both are put to," but here, he adds, the "analogy ends," as the inflorescence and the part of the plant from which it proceeds are quite distinct. Describing further on, Dr. Hooker says the rhizomes are from 3 to 4 feet long and 2 inches in diameter, full of a spongy, fibrous texture, having a horseradish flavour and bearing at the end "an extremely large head of leaves, sometimes 18 inches across, so like common Cabbage that if growing in an English garden in company with their namesakes they would not excite any particular attention."

As in the ordinary Cabbages, the inner leaves form a dense white heart, which Dr. Hooker says tastes "like Mustard and Cress, but much coarser," the entire foliage abounding with an essential oil, "pale yellow, highly pungent, and confined in vessels which run parallel to the leaf, and are very conspicuous if the head be cut transversely." During the entire stay of the "Erebus" and "Terror" in the dreary abode of the Pringlea, Dr. Hooker tells us daily use was made of the plant either cooked by itself or boiled with ship's beef and pork. The essential oil above alluded to, he adds, gives a peculiar flavour, which, however, "neither officers nor men disliked," and which rendered it more wholesome than common Cabbage, "for it never causes heartburn or other symptoms, which the latter does." As remarked at the commencement of this article, it is to the "Challenger" Expedition we are indebted for the seeds from which the young plants now in Britain have been raised, as also for the more intimate knowledge of the botanical structure of its flowers, perfect specimens of them, forwarded by Mr. Mosley, having reached England for the first time in the course of last year. The chief peculiarities of the flowers, as compared with others of the order, appear to be the absence of petals and of the usual glands between the bases of the stamens. Through the kindness of Dr. Balfour one or more young plants are in possession of Dr. Moore at Glasnevin, and from the same quarter Dr. Edward Perceval Wright, Professor of Botany, T.C.D., also had a couple of plants, which, kept in a cold frame in his garden, have, we are glad to say, come safely through the winter. Of these we hope to see and say more by-and-by.—(*Irish Farmers' Gazette.*)

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Phyllocactus biformis. *Nat. ord.*, Cactaceæ. *Linn.*, Icosandria Monogynia.—Flowers crimson. "A native of Honduras, whence it was introduced by G. Ure Skinner, Esq., in 1839. He sent it to the late Sir Charles Lemon, who had a famous collection at Carclough, in Cornwall; and it has been long cultivated at Kew, where it flowered in January 1874."—(*Bot. Mag.*, *t.* 6156.)

Pentstemon antirrhinoides. *Nat. ord*, Scrophulariaceæ. *Linn.*, Didynamia Angiospermia.—"A very charming shrubby half-hardy plant, discovered in California by Dr. Coulter nearly half a century ago, and, as far as I am aware, found by no one since till Bolander gathered it in the Santa Maria Valley, San Diego. It is remarkable for the lemon-yellow colour of its flowers in a genus of which most of the species are red, violet, purplish, or blue, colours which rarely occur along with yellow in one group of closely-allied vegetable forms, though instances do occur, as Gentian.

"Pentstemon antirrhinoides flowered at the Royal Gardens, Kew, in September, 1874, from specimens sent by Mr. Niven of the Hull Botanic Gardens."—(*Ibid.*, *t.* 6157.)

Pyrus prunifolia. *Nat. ord.*, Rosaceæ. *Linn.*, Icosandria Monogynia.—"It is singular that no good figure should exist of so beautiful and well-known a tree as this, and one introduced before 1758, which can only be accounted for by its being usually confounded with the P. baccata, which was not introduced till 1784, and from which its connate styles and totally different fruit, crowned by the persistent calyx, at once distinguish it. I have seen no native specimens, and though stated by the earlier authors, including De Candolle, to be a native of Siberia, Ledebour does not seem to have known it,

for he quotes De Candolle and Willdenow's description, giving Siberia with a query as its habitat; and, though described by Miller in 1760, is a native of Dahuria, whence it was introduced into the St. Peterburgh Gardens. It is not included in Turczaninov's Flora Baical-Dahurica.

"Pyrus prunifolia has been an inhabitant of Kew for upwards of a century, and flowers in April and May, fruiting in October." —(*Ibid.*, *t.* 6158.)

Masdevallia Peristeria. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Flowers yellow, dotted thickly with crimson. "The lip is, as Reichenbach remarks, very singularly coloured, being covered with innumerable close-set amethystine papillæ on a white ground. The name is given in allusion to the likeness of the top of the column and petals to those of the Dove Plant (Peristeria elata), where the anther case represents a dove's head, and the outstretched tips of the petals its wings, as in the Church's symbol of the Holy Spirit, whence the name of El Spirito Santo was given to the Peristeria by its discoverers the Spaniards. Masdevallia Peristeria is a native of New Grenada, whence it was imported by Messrs. Veitch. The plant flowered in April."—(*Ibid.*, *t.* 6159).

Fourcroya undulata. *Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia.—Flowers green. "It is a native of the provinces of Chiapas and Tabasco in Mexico, where it was found by the traveller Giesbrecht, who sent it to Verschaffelt's splendid establishment in Ghent (now incorporated with the no less celebrated Brussels one of Linden). The Kew specimen flowered in the Royal Gardens in November, 1874, rather later than the other species, than which it may want a warmer climate, as that of Chiapas and Tabasco is described as hot, damp, and its hills as clothed with a tropical forest. It was received from the rich collection of W. W. Saunders, Esq., F.R.S." —(*Ibid.*, *t.* 6160.)

Cyrtopera sanguinea. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—"The colour of the flower as shown in my own sketch is a dull reddish-purple, extending over the short spur, with a rose-red limb to the lip; colours which induced Dr. Lindley to name the species sanguinea, a name hardly justified by those hues.

"C. sanguinea inhabits the tropical region of Sikkim, and is found in dense forests at 3-5000 feet elevation. The Kew plants flowered from tubers which have been received both from the late Dr. Anderson of the Calcutta Botanical Gardens and Mr. Gammie of Darjeeling."—(*Ibid.*, *t.* 6161.)

Pear.—*Lucy Grieve.*—"This variety is remarkable for its long, narrow, willow-like leaves, which give the tree a peculiar appearance. The fruit is full medium size, oblong pyriform, broadest just above the middle, its average weight exceeding 7 ozs. The stalk is over half an inch in length, set in a very shallow depression, the sides of which are slightly unequal; the eye is closed, and set in a shallow even cavity. The colour is a clear deep lemon-yellow, thinly marked with russet dots, and having a small russet patch about the eye and the stalk. The flesh is moderately firm, fine-grained, tender, and melting, very juicy, with a rich luscious flavour, and a slight and agreeable dash of acidity, such as is occasionally met with in the Glou Morçeau. The odour of the fruit is penetrating and agreeable, and its appearance something like that of an elongated Glou Morçeau. A first-class certificate was awarded to this fine new Pear by the Fruit Committee of the Royal Horticultural Society at its meeting of October 23rd last. Ripe and in excellent condition about the middle of October." —(*Florist and Pomologist*, 3 s., viii., 85.)

NOTES AND GLEANINGS.

We are glad to hear that there is no chance of the contemplated Exhibitions of Amsterdam and Brussels interfering with each other. At a meeting of delegates held at Antwerp during the Exhibition just closed it was decided that Brussels will celebrate its centenary next year, and that Amsterdam will hold its Great Exhibition in 1877. Will London be ready by 1878? Let us hope so.

—— The following candidates have been duly elected Fellows of the Royal Horticultural Society since the 1st of January last—viz., B. Bate, Hon. and Rev. J. T. Boscawen, Mrs. A. Cumberbatch, Mrs. George Hamilton Dundas, J. Godman, Captain F. H. Hamilton, Mrs. Harrison, Charles F. Haywood, Mrs. C. Kemble, Mrs. E. S. Kuipe, Thomas Charles Perceval Lefroy, Thomas Alfred Logan, Major-General P. L. Macdougall, R. L. Pemberton, Miss R. Pennell, E. J. Reed, C.B., M.P., F. Ricardo, William Scott, Thomas Shedden, James Tedder, Earl of Wicklow, John A. Clarke, Major-General F. Conybeare, Mrs. Dansey, J. A. Fullarton, Vice-Admiral W. W. Hornby, Charles G. L. Kelso, J. L. P. Lebègue, Mrs. Lloyd, James Murray, W. C. T. Padday, Hon. Leopold W. H. Powys, Mrs. Young, Hon. Evelyn Ashley, M.P., I. de Salles, Mrs. C. D. F. Philips, Thomas William Angell, Hon. W. Lowther, M.P., &c.

—— To avoid clashing with the Manchester Show, that to be held at the Crystal Palace is postponed to the 29th of May.

—— Our correspondent Mr. J. Wright, on retiring from the service of the Hon. A. Leslie-Melville, had a handsome barometer presented him by the family as a tribute of the esteem in which he was held by them; also for his services in the village he was further presented with a valuable timepiece. Mrs. Wright and family had also gratifying tokens of goodwill from the Melville family.

—— The cultivation of the Tobacco plant in Algeria has been carried out very successfully, the soil and climate of that country being well suited to the growth of the plant. In 1874 no less than 9,700,000 lbs. were produced and passed through the State warehouses. The value of this crop was £141,224, or nearly double that of 1873. The experiment—though it is no longer merely an experiment, but a practical industry—has been carried on since 1847, and during the past twenty-seven years about 140,000,000 lbs. weight of Tobacco has been produced and sold.

—— It is stated that the Italian Government, following the course it has already adopted on previous occasions, will gratuitously distribute this year five thousand plants of Eucalyptus globulus for cultivation in the Agro Romano, especially in the spot infected by malaria.—(*Nature.*)

—— Professor Vogel of Munich has lately published, says *Galignani*, some curious experiments on camphor and its physiological action on plants. In 1798, Benj. Smith Barton first announced the stimulating action of camphor on vegetable organisms. He stated that a Tulip with its stalk dipping in a solution of that substance withered much later than others kept in common water; and that a yellow Iris that was about to fade was reinvigorated for a few hours by means of camphor. Barton therefore came to the conclusion that this drug acts upon plants as a stimulant, much as spirits do on the animal frame. These all-but-forgotten experiments have lately been resumed by Professor Vogel, who has lately communicated his results to the Academy of Munich. He first prepares a homogeneous solution of camphor by triturating it with distilled water, and then shaking it up with a larger quantity of the same; and into this he puts his plants. Two branches of Syringa (common Lilac) in blossom, of equal size and vigour, were selected; one of them was put into common water, the other into the camphorated solution. A remarkable difference was soon noticed. After the lapse of twelve hours the former was already drooping and nearly faded, while the latter was still erect and apparently as fresh as ever, some of its buds having even opened in the interval; and this healthy condition lasted three days. In another experiment a branch of Lilac which was nearly dead was put into camphorated water and revived for a short time. The action of camphor is less powerful on the Vine, and scarcely of any effect on Black Elder. The idea now presented itself that this drug might also have some action on seeds, and accordingly some of Lepidium sativum, or garden Cress, were subjected to this treatment. They were chosen very old, because in that state their germinating power is much weaker than when they are new. The seeds were placed on blotting paper in porcelain plates, one portion being wetted with the camphor solution and another with common water, another piece of blotting paper was laid over each. The germinating power of these seeds is considered not to extend beyond three years, and yet, under the influence of camphor, some of 1869 germinated in the course of twenty-four hours, and others of 1871 in seven hours, while those exposed to the action of pure water either did not give signs of life, or, at least, very imperfectly. From these and similar experiments it may be concluded that camphor is a valuable agent in horticulture.

Planting Potatoes.—Now is the time (April 4th) to plant early Potatoes. The whole of our Potato borders were deeply dug, and even manured in November, and now the soil is like a bed of ashes. Draw the drills 2½ feet apart, and plant the Potatoes 18 inches. Give them a top-dressing of burnt ashes

mixed with rotten leaves; plant near the surface. When up earth them over until about the middle of May, and you will, season being favourable, be rewarded with fine, large, clear, and good Potatoes.—R. Gilbert.

THE CASTOR-OIL PLANT.

Ricinus communis, or Castor-oil Plant, is a native of India, and was introduced to our stoves in 1548. It has long been cultivated, and from the supposed resemblance of its beautifully mottled seeds to an insect known as the tick or ricinus, the ancients applied that name to the plant. Seeds have also been found in ancient Egyptian mummy cases, and it has been known as a medicinal plant from time immemorial.

It is cultivated as a commercial product in the Levant, Spain, Brazil, and other parts of the tropics. Some of the species are found growing spontaneously in Italy, choosing as their habitat the moist thickets on the southern coast. From the province of Verona the largest supplies of both seeds and oil are now drawn, and from nowhere can such pure oil be had as from the manufactories of that province. The plants are grown in fields of rich soil in rows 4 to 5 feet apart, and 3 feet distant in the rows. They are earthed-up as they grow, and in September the seeds are gathered by women. It is stored and manufactured with great care, and good seed will yield about sixty-six per cent. of the commercial oil.

As ornamental plants the different varieties of this genus are largely cultivated. The large, broad, palmate leaves, from which is derived its popular name, Palma Christi, are very effective by their rich glaucous purplish hue and the metallic lustre of their surface. It was formerly grown only under glass, but since subtropical plants for our gardens have become popular, the Castor-oil Plant has formed an important part of this extremely ornamental mode of garden decoration.

Fig. 63.—Castor-oil plant (Ricinus communis).

When well grown few plants are more stately than this, or form a more distinct feature amongst the occupants of the garden. R. sanguineus, R. Obermanni, and R. purpureus are amongst the most effective varieties; where one only is required, that first named may be selected.

They are easily raised by sowing seed at the present time. To insure a free germination the seed must be placed in brisk bottom heat, such as is afforded by a Cucumber or Melon frame. It may be sown one seed in the centre of a small pot, or several in a pan, the seedlings to be afterwards potted.

The plants must be grown in a genial temperature of 60° at night, and be shifted into larger pots as they require, and be kept in a light place near the glass. By this means they will be fine plants by the 1st of June, when, after being duly prepared, they may be planted out.

The soil suitable for potting them is rich turfy loam with a little peat and leaf mould. The plants require copious supplies of water when in active growth. The soil in which they are planted should be rich and deeply worked, and the site sheltered from strong winds, which cause injury to the foliage.

A point of importance to bear in mind in the raising of these plants is for the cultivator to correctly calculate his conveniences for growing them on without check. February is not too early to sow the seed in one garden, but March sowing may be premature in another. The time for sowing is to be decided by the means of growing the plants freely afterwards. By attention to this, those having no other convenience than a warm frame and cool structure or two may have attractive Castor-oil Plants. In this case the end of April will be sufficiently early to sow the seed, and by the time the plants are established the weather will permit their being removed to an unheated structure without injury.

Plants from seed sown in April and having no obstacles to free growth will have a better appearance in August than those from seed sown two months earlier, and which had become drawn and obstructed in growth by lack of suitable conveniences. This is a rock on which many a wreck occurs. Safety lies in calculating means, and from this determining the right time to sow seeds of tender plants.

Those who have beds filled with annuals which are not off the ground until July, may at that time have the beds refilled with Castor-oil Plants from seed sown in April, or even as late as the first week in May, and the plants be grown on, liberally and freely, in frames heated by the sun alone. By rich ground and an abundance of warmed water the plants, if not tall, will be highly ornamental through the autumn months, and will increase in beauty until destroyed by frost. Single plants in suitable places always look well. Plants from seed sown late will not flower, but that is of little or no importance, as the ornamental appearance of the plant is due to its noble growth and beautiful foliage; yet in the hot summer of 1868 we saw plants flowering out of doors in the midland counties from seed which had been sown in April.—W.

AQUARIUM AND FLOWER STAND.

How to Fill the Aquarium.—First cover the bottom of the tank to the depth of one half-inch with pure fine sand, on the top of which put an equal quantity of fine gravel; over this gravel sprinkle small ornamental stones, shells, coral, &c. Everything put into the tank must be thoroughly washed. Next put in position an ornamental central piece of coral, stone, or anything out of which you can construct an arch through which the fish can readily swim. Now fill the tank one-third full with pure cold water from a lake, river, or well.

Plants.—The best aquatic plant for aërating the water in the aquarium is Anacharis canadensis, found growing (in America) on the bottom of nearly all sluggish streams and ponds. The Valisneria spiralis is the next best, after which comes the

Myriaphyllum verticillatum. There is a species of Conferva found in rapid streams attached to stones that is an excellent aërator, valuable especially during the winter when other plants do not flourish. If you have the Anacharis remove all its decayed stems and leaves, wash it clean, and arrange in groups of ten to fifteen. Make a hole in the sand, insert the root end of the plants, and secure in this position by pressing small stones about them. Insert in this way about six to eight groups, and be careful to make them secure at the bottom. Roots are not necessary, as the cuttings will soon send out fine white rootlets. Now fill up the tank with water to within 1½ inch of the top. Wait two or three days before introducing the fish, that the plants may have time to commence growing.

The Fish.—Almost any small species of fish may thrive in the aquarium; but we think the best for the purpose are the red-bellied minnows and sticklebacks, all found in small streams. Select small fish; from four to eight for a tank holding from eight to twelve gallons. Such a tank will support four small ones better than one larger. Introduce also ten or twelve water snails. The Lymnæ are the best; yet the Planorbis and the Physa are interesting. Better, however, have a few of every kind you can find in the ponds and stagnant pools in your vicinity. They feed on the softest parts of aquatic plants, and do not exhaust the oxygen mixed with the water, for they are air-breathing, and have to come to the surface to take in a supply of air to be used while they go about cleansing the plants and glass of the tank with their curiously-constructed jaws.

Food.—The best food for the fish are angle worms and flies in summer, and fine bits of fresh raw meat in winter. Never give the fish more than they can eat at one time, for whatever is left will injure the water.

Position.—The best place for the aquarium is where it will be exposed to the sun at least one hour each day, in order that the plants may exhale oxygen, which can only take place under the stimulus of light. Too much light, however, is to be avoided, as the fish do not thrive when exposed to the sun, and the glass will be soiled by confervæ, a green vegetable matter. In summer an outdoor position is best if there be sufficient shade. It is well to cover the aquarium, both for the shade and to keep the fish from leaping out of the tank.

Cleansing the Aquarium.—If well balanced with plants, fish, and shells, the water will remain sweet for an indefinite time. We have an aquarium that has been in service for the last twelve years, and which does not require a change of water oftener than once or twice a year, and then only to renew the sand which becomes filled with excrementitious matter.

Amphibious Animals.—If lizards, frogs, or other amphibious animals are introduced, they should be provided with some surface above the water to climb upon. The rocks may be built above the water, or a piece of flat cork may be allowed to float upon it, on which the animals will climb.

Gold Fish may be kept ten or twelve years (their average period of existence) by using the following precautions:

1st. Allow not more than one fish to two quarts of water.

2nd. Use the same kind of water, whether well or river; change it every other day in summer and twice each week in winter.

3rd. Keep clean sand and pebbles at the bottom, washing it occasionally or replacing with a fresh supply.

4th. Use a small net rather than the hand while changing the water.

5th. Feed with plain biscuit, yolk of egg, lettuce, and flies, once each week, except in cold weather. Feed but little at a time. Remove any crumbs that may remain on the surface after feeding.

6th. Do not feed at all from November to the end of February, and but little during the following three months.

7th. If there are growing plants in the aquarium water need be changed but rarely.

8th. Keep from sunshine and in the coolest part of the room.—(*New York Pirate.*)

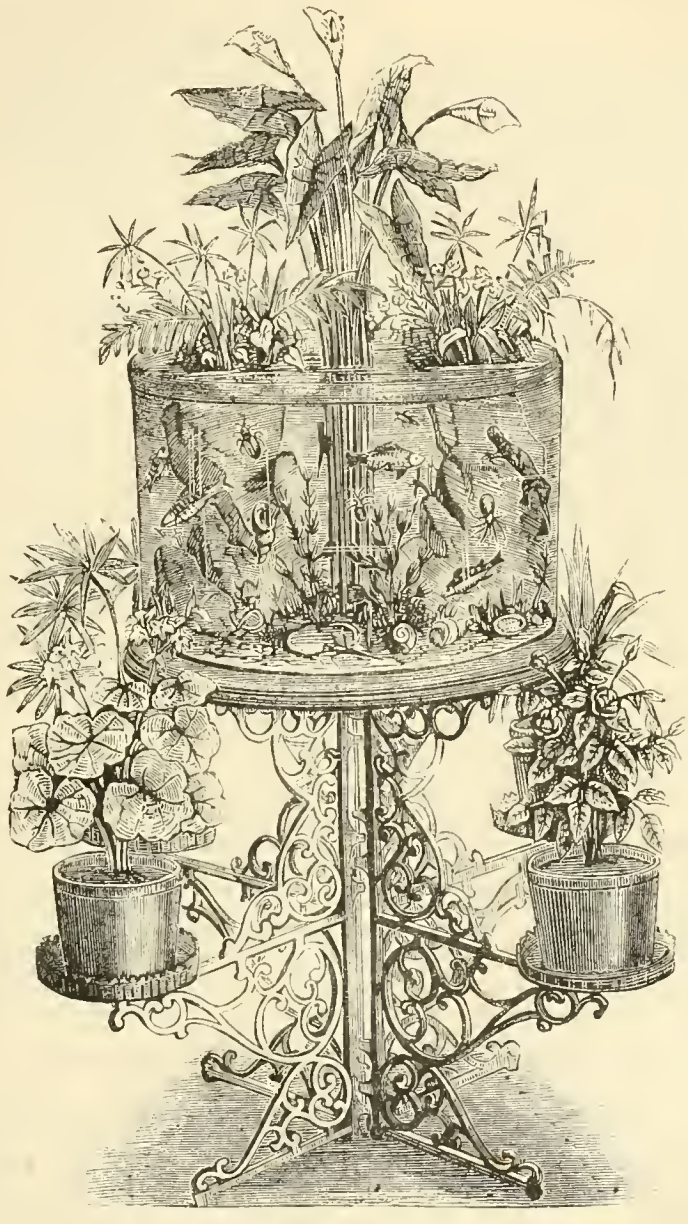

Fig. 64.—Aquarium and flower stand.

William Austin.—The obituary notices which have from time to time appeared in the Journal have recorded the passing away of men famed as amateurs, as gardeners, or as patrons of horticulture; I will add a passing tribute to one in a more humble rank of life, who for the qualities which I shall presently allude to was, I think, without an equal. But who was he? it may be asked. Anyone who had frequented our metropolitan shows will not fail to have noticed wherever my friend Mr. Turner's plants were put up, busy amongst them, diving-in where others "feared to tread," and looking at all with a critical eye, the active form of William Austin. He was really only Mr. Turner's carter, but I never met anyone who had a better taste for arrangement than he had, nor one who could detect any little faultiness

either in those belonging to Mr. Turner or others. He was, moreover, an excellent judge of plants and flowers, and I have often, when the plants were staged and I had nothing to do in the way of judging, said, "Now, Austin, come round and tell me where the prizes ought to go," and rarely have I found him at fault; and when I add to this that he was a faithful and honest servant, and had lived with his employers for thirty years, I think I have established his claim to this brief notice.—D., *Deal*.

WHITE AND CLUSTER ROSES.

"Cornubia" (page 256) has done well to direct attention to this enjoyable type of Roses, and to the scant attention they receive at our exhibitions. If their individual blooms are less imposing than those of the Perpetuals, the clusters render the plants admirably adapted for garden decoration. We seldom find them cared for except in very old or cottagers' gardens, yet how cheery and sweet and homely they are! They are excellent for shrubbery cultivation, rich soil being not at all essential to their free growth, and their profuse blooming and lively colours show to advantage in the dark evergreen setting which the shrubs afford.

They are extremely suitable as summer screens in covering bowers, rustic fences, and piles of roots, and possess an easy airy gracefulness and a delicate perfume which cannot fail to be enjoyed. Their finely-wreathed clusters of blooms may, too, be gathered by armfuls without robbing the plants, and the free natural arrangement of these tresses are ever attractive in our dwellings. The tendency of the times is to foster the increase of massively-formed highly-coloured Roses—and splendid they are—yet at the expense of perfume and elegance of habit of the clustered-flowering varieties.

Surely, as "Cornubia" has suggested, means may be afforded to bring the cluster Roses into our exhibitions, and thus add diversity to the shows; also to let the public see how attractive they are in themselves, and how eminently they are suited to meet the special requirements of a flower-loving world. I hope "Cornubia" will take up the theme again, and tell us more about this charming class of Roses.—Aimée Vibert.

RUSSELIA JUNCEA.

Judging from the miserable starved appearance which Russelia juncea has in some gardens, one would think that it was difficult to grow, and from the way in which it is in others "stuck" in any out-of-the-way corner of the house, to be hardly worth growing. Now my experience of this plant is, that it is very easy to grow, and, when well grown, one of the handsomest and most useful early-winter-flowering greenhouse plants we have. I have had splendidly-flowered plants of it from 3 to 5 feet high, one mass of bloom from top to bottom, and continuing in flower from three to four months.

The way I recommend it to be grown is as follows:—Suppose the plants to be just done flowering, keep them rather dry for six weeks or two months; by this time it will be early spring. The plants should be then shaken out of the pots, and the balls carefully reduced and repotted in the same-sized pots, which should be well drained. The compost ought to be a good fibry loam, with a good allowance of half-rotted stable-droppings, that from an old mushroom-bed does very well. A few of the branches ought at the same time to be cut off close to the neck of the plant, which will encourage new shoots to make their appearance from the base, and it is to those new shoots we must look for our future plant.

The plants ought to have a good position in the house, and be carefully and sparingly watered until the new shoots make their appearance, when water can be given more freely. As soon as the young shoots are an inch or two in length, a few more of the old branches can (if an old plant) be cut away, leaving enough of the freshest of them to nicely cover the pots. The plants at the same time ought to have a good shift, and no more shifting will be necessary.

The old wood should be allowed to hang down, and the new shoots encouraged to grow upright; but they must not by any means be closely tied, as at this period they grow very fast; they should only have as much support as to keep them from touching the glass, or coming in contact with anything else, as they are very brittle, and would snap off like young Asparagus tops; in fact, if growing very strong they somewhat resemble that plant: care should also be taken that they are not broken by the hand when watering, as it is ruin to them to be stopped; neither must they be allowed to suffer for the want of water; for one need not expect to have very nice specimens if checked in any way when making their growth. As soon as they have nicely established themselves in their new pots they ought to have plenty of liquid manure. I find they are very partial to soot.

The point I strongly recommend is to get a fresh growth from the bottom every year. My experience of this plant convinces me that this is by far the best way of growing it. Grown upon this system, it will be useless to expect large well-bloomed specimens if they are half starved. They must have fair pot-room, and be grown as vigorously as possible. They can do with as much liquid manure as almost any other plant.

Most cultivators keep the old wood year after year, as they would that of a hardwooded plant. This, I am convinced, is not the best way of growing them, for they seldom flower so well a second time upon the old wood. The flowering period will be considerably prolonged by giving them a good top-dressing of very rich compost.

After they have completed their growth they can be neatly tied to an upright stake; two of the leaders will be quite enough to take up their full length; the others can be tied half-way up, and allowed to hang down. Treated in this way, they will make handsome specimens, by no means to be despised as exhibition plants at a provincial flower show.—R. Reid (in *The Gardener*).

THE POTATO DISEASE.

In the issue of your Journal of date 14th January, under the heading, "Jottings of Last Year's Gardening," it is observed, "Culturally the Royal Agricultural Society has, to its own satisfaction no doubt, proved there are no kinds of disease-proof Potatoes. It is hoped the public, and especially the ninety-four essayists, will be convinced that the prize of Earl Cathcart was 'justifiably withheld.'" On what ground the public could have come to such a conclusion I am not aware, but as one of the ninety-four essayists I most emphatically deny that all the essayists have been shown any valid cause for admitting that the prize was "justifiably withheld." As an essayist I consider the decision a very shabby one, and the essayists have been treated with but curt justice and courtesy. I, however, exonerate the distinguished nobleman who so generously offered the prize from participating in the proceedings.

It may be true that the essayists did not succeed in working a miracle by the "prevention of Potato disease"—a feat, I venture to think, beyond the power of man—neither is it in our power to "prevent" frost; but although the "prevention" of the latter is not within our power, we can, by the adoption of suitable remedial measures, render its injurious effects comparatively harmless. Precisely so, I presume to think, will be the case with regard to Potato disease. It appeared to me that the essayists were thrown overboard to meet the bright idea which was conceived of inventing a kind of miraculous Potato which was to be a "disease-proof Potato!" which, if successful, would no doubt have caused a sensation, and made the fortune of the lucky person who could make the public believe in its efficacy.

I along with, I presume, the other essayists, was invited to be a competitor in testing the efficacy of this golden Potato, being given to understand that a considerable number of agriculturists had agreed to do so; but having had no faith whatever in this miraculous tuber, nor in the conditions of competition, I made no response. Since then I understand the project has been abandoned, but it is to be hoped the essayists, notwithstanding their rebuff, will prosecute their respective theories, the investigation being of incalculable national importance, and by no means a hopeless one. I feel assured that if "prevention" is impossible, satisfactory remedial measures will ultimately be found.

One hundred and fifty years ago he was reckoned a very clever farmer who could from his scanty and precious stock of seed spare a dish for his "Christmas dinner," a scarcity arising from causes which experience and skill afterwards removed, as it is to be hoped will be the case with Potato disease, on which I do not mean to inflict on you a lengthened disquisition.

I cannot close those remarks without expressing my concurrence in the very able, practical, and judicious views relative to Potato disease expressed in the article in your issue of the 4th ult. signed "Beta," whose views I thoroughly endorse.

Although the locality therein referred to had the greatest rainfall in England, it did not follow that Potato disease must have ensued there, something more than excess of rainfall being required to produce Potato disease, which in all probability we may have periodically, like the somewhat analogous diseases of pleuro-pneumonia — foot-and-mouth, and grouse disease.—C.

TREE MIGNONETTE.

There seems to be an idea among some gardeners that Tree Mignonette is difficult to grow. Such, however, is not the case; for if it received half the attention that other things have, such miserable objects as one often sees called Tree Mignonette would not be met with. We have six pyramids and two standards, the largest pyramid being 4 feet through and 3 feet high, the standards having heads 2 feet through. We have cut abundance of bloom from them since the beginning of October, and shall be able to continue doing so until there is plenty outside. Mr. Wood's treatment is briefly as follows:—Sow the seed, two or three in the centre of thumb pots, the beginning of April, and as soon as the seedlings are large enough thin them out to one in each. As soon as the pots are filled with roots give them a small shift, and continue doing so until the size of pot is reached in which you mean your future specimens to remain. Pinch all the flower buds out as soon as they make their appearance until the end of August. When they are in flower weak manure water may be given them two or three times a week. Loam, peat, and leaf mould in equal proportion, with a good sprinkling of silver sand, suits them well.—Lockhart M'Intosh (in *The Gardener*).

NOTES on VILLA and SUBURBAN GARDENING.

Garden Walks.—At this time, which may be considered the beginning of a season of pleasure to be derived from a garden, it would be difficult to find more important work to be done than by having the *walks* in good order. If they are formed of gravel the surface should be turned over to the depth of at least 3 inches, which will not only destroy both weeds and moss, which is very desirable at the commencement of a season, but the walks will present a fresh and lively appearance, and be more agreeable to walk upon during the summer. But, like most other things, the work must be done with judgment—first, if the edges of the walks are of either Box or grass they should be neatly trimmed, the former by clipping and filling up all vacancies, and the latter by being smoothly pared with the edging iron; and if there are borders beyond these they ought to be first dug and all completed before the walk is touched. By first completing this heavy work of border-digging a considerable time is afforded for the walk to settle down firm again before being much used, which is important as contributing to its smoothness and beauty.

In turning gravel walks let the work be done in dry weather, and as the turning goes on do not go far before you rake the surface even and to its proper shape, rolling it regularly as you go on, say about every 40 feet, for gravel always binds best when it is first turned up, because it is then moist on the surface. It may be necessary to rake the walk both lengthways and crossways, and work the surface free from holes and make it all even alike, this must be done before any rolling. For some time after the walks will need frequent rollings. If the walks are of turf, which is seldom seen in this part of the country, they must be first swept and well cleaned, then pare the edges and keep the grass well rolled and mown during the summer.

The Lawn.—Everyone knows and appreciates clean and well-kept lawns, and to have them so requires labour and good management. This time of the year is the most important, for what is to be done in the way of levelling should be done now. The grass should be well swept when dry, and also rolled, and the first time it is mown, which is not always the easiest, it should be cut rather close and again rolled to compress the surface; after that the grass which grows is young, consequently the machine or scythe works easy and well.

Flower Beds.—Take the first opportunity to arrange the plan of bedding for the season if it has not already been done, particularly as the preparation of the soil for any particular or choice bedding plant must be now considered. I advise that the soil in the beds be once more turned up to the original depth advised for the winter digging, and all additions as to soil or manure be now completed. As a rule, the most usual sorts of bedding plants do well in ordinary soil, but a change is beneficial, and I question if it would not be an advantage in the case of the amateur or occupier of a small garden situated near the town who cannot, without considerable expense, obtain an entirely fresh or new soil, to half empty his flower beds and transfer the soil to his kitchen garden, and make up the difference from that garden in return. I am satisfied he would find this mutual exchange beneficial to his plants; and again, although it is not to be expected that an amateur can make any very special preparations such as a professional gardener has the chance to do, yet if he cannot do as I suggest above, he can study and provide a little difference in the soil according to the requirements of different plants.

Many complain of and have discarded the Calceolaria. There is no better plant for free-flowering than this, yet it needs special treatment. As to soil, it enjoys a firm, rich, deep loam; but in hundreds of cases it cannot have it, but instead, if the soil is light, it can have a layer of rich manure placed about a foot under the surface, and the surface itself pressed firm almost to treading during planting. Plant out early, say by the last week in April, and do not allow them to stand in close quarters till the plants are drawn up and the wood become hard, and the eyes which ought to produce shoots are all dead. This is not likely to be satisfactory. I do not believe this plant likes to be interrupted at the root after a certain stage; hence my reason for advising early planting. I do not think they can be overgrown in the beds.

Pelargoniums of the Zonal class may be overgrown in a very rich, damp, heavy soil. In such soil they are pretty sure to make too much leaf and growth rather than a profusion of bloom. This is rectified if the soil is less rich and lighter; whereas the variegated sorts, which are grown more for their leaf-colouring, require a rich soil and to be grown vigorously, as witness the benefit such a soil imparts to Flower of Spring.

Enough has been said to illustrate what I mean by special preparation for different sorts of plants, a matter which is too little thought of by many who are admirers of the usual kinds of bedding plants when well grown, but who lose the chance of doing the work at a time when it can be most conveniently done, which is during this month.—Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

But little work can be done in this department now, except to protect the trees from frost and feathered depredators. So far the weather has been exceptionally fine, clear days, with a little sun, and a night temperature sufficiently high to dispel all fear of injury from frost. We would rather have the days cloudy than continuous sunshine, which hurries out the blossoms on wall trees too rapidly. The Apricots have not required shelter so far, and the pistils pushing out prominently show that the blossoms have set well. Peaches and Nectarines will soon be in blossom on the walls. It is easy in small gardens where but few trees are grown to look carefully over the young shoots before the blossoms expand, and with a small sponge and soapy water remove any aphis or scale. It is hopeless to attempt this after the blossoms are open, and before the syringe can be used the aphis has attacked the young leaves and caused them to curl up.

It cannot be too much impressed upon all who would be successful gardeners that all insect pests should be destroyed as soon as they are observed, and a watchful eye should be kept upon all trees that are likely to be attacked. If the present fine weather continues the protecting material will not be required, but it ought to be in its place in case a sudden change should occur. Not only on the walls, but in the open garden, all sorts of hardy fruit trees give promise of being covered with blossoms.

We have again run the Dutch hoe through the Strawberry quarters. It is just the surface that requires to be stirred. If the hoe is pushed into the ground too deeply a large proportion of the roots will be destroyed. When the plants have grown well and the crowns are fully developed the whole body of the ground from the surface downwards is a mass of roots, and quite close to the surface will be found a network of active hair-like fibres, ready to absorb the manurial properties of the surface-dressings which are applied as soon as the flower trusses are thrown-up.

Now is a good time to put in Strawberry plants. If the runners have been thickly placed in beds in autumn they remain in the same position through the winter, and are now starting into growth. Many persons have not the opportunity to plant their beds at the proper time—that is as soon as the runners can be obtained. The plants put out now will, if strong, throw up flower trusses, but these must be cut off, as well as any runners that may be formed. Those who forced Black Prince or Keens' Seedling early will now have a quantity of plants from which the fruit has been gathered. As these plants are taken out of the forcing houses they may be removed to a cold frame for a week or ten days, the frame to be kept close for day or two, so that the leaves formed in a high temperature may not suffer. They ought to have a large supply of water a the roots, so that the ball is quite moist to the centre. If such

plants can be planted on well-prepared ground they will produce a crop of fruit in the autumn. The roots, being matted firmly together, forming a ball impenetrable to water, must be loosened out with a pointed stick, and the mould ought to be very firmly pressed round the roots when planting.

FRUIT AND FORCING HOUSES.

Vineries.—We have finished thinning the Grapes in all the houses. This is an operation that will not stand over. The berries in their early stages swell so rapidly that unless they are thinned-out, as soon as ready, the quality of the fruit is deteriorated. Black Hamburgh, Buckland Sweetwater, and all free-setting varieties are ready for thinning in ten days after the first flowers on the bunch are observed to open. Muscat of Alexandria, Canon Hall Muscat, Golden Champion, and all the shy-setting section cannot be done until it is perceived what berries are set; this will be about four or six days longer than the others. It requires some experience to know how many berries may be removed, and it is much the best way to thin-out the whole at once. Many persons make a second thinning just before stoning, and it is desirable to look over the bunches at that time, as even with the best management some of the berries may be too much crowded, or a few badly-formed berries require to be removed.

The growing shoots are now tied down into their places, and it is necessary to look over the Vines once in ten days, and to stop back any growths that have been formed; but if the Vines are carrying a good crop of fruit but little growth will be made after the berries are thinned-out.

Late houses that have not received any artificial heat, except so much as kept the frost out, are now starting into growth. No bedding plants should be in the house at this time, but if it is required a few pot Roses, or any other plants requiring to be forced, may be placed in the house until they are likely to be injured by shade from the leaves. Camellias that have finished flowering may also be started into growth here; the moist atmosphere and daily syringing is congenial to them, causing a healthy vigorous growth.

Pot Vines intended for early forcing next year should now be pushed along with a high temperature, the leaves to be freely exposed to the light, and sufficient space allowed for them to develope themselves. Plants crowded together in a tan bed will not give satisfaction. The strongest and best-ripened canes are produced if the pots are placed on a stage over hot-water pipes, not plunging the pots at all, and they will be strong enough, if the compost is good, without any manure water being used. The canes ought to be trained-up close to the glass, but not so close that the leaves come in contact with it. Syringe the leaves daily to keep them free from spider.

Orange Trees in Pots.—As it is not necessary to have a house entirely devoted to Fig trees to obtain a small supply of Figs, in the same way a few dishes of delicious home-grown Oranges may be obtained from half a dozen pot plants placed in a house with a high temperature, the only stipulation being that they are not under the shade of Vines or other dense-foliaged plants which are trained to the roof. Tangierine Oranges are the earliest to ripen, but fruit that is just now set will not be ripe until November; and later sorts, such as St. Michael's and Maltese Blood, will not be ripe until Christmas. The only insect pest that is any trouble to us is the brown scale, and the best way to banish it is by hand-washing. If the trees are pretty well free from it now, vigorous syringing daily will keep the leaves clean and the plants healthy all through the summer months.

GREENHOUSE AND CONSERVATORY.

There is no lack of flowers at present in this department. The late Camellias are unusually fine, and any Azaleas that have been forced retain the flowers in good colour so much longer now than they do if allowed to open without any forcing in June. Deutzia gracilis with its clustering sprays of snowy white flowers lasts long in beauty if the plants are kept cool and shaded from scorching sunshine.

Much of our time has been taken up in preparing Hyacinths, Tulips, &c., for exhibition. Tulips require nothing more than a slender stick to support the flower stalk; the flowers are also tied round with a strip of matting to prevent the petals from being shaken off during transit. The Hyacinth spikes are tied to a wire support, and no dressing is allowed except to arrange the bells with a cedar pencil. Many of the sorts have the bells naturally drooping, but the best exhibition varieties are those that have them stand out in a horizontal position, so that the spike forms a cone narrower at the top than the base, and regularly covered with perfectly shaped bells. Stiff healthy foliage is quite as essential to success as well-formed large spikes.

any of the Hyacioths exhibited this year were faulty in this respect, the foliage being so weak that it hung quite over the pots. This is caused by keeping the plants in a house badly ventilated or too far from the glass. Even if it is necessary to push on the plants to have the flowers open before a given day they ought to be placed quite near the glass, and a little ventilation should be allowed in the house all night, and the atmosphere of the house should not be too much charged with moisture.

Stage Pelargoniums are now growing vigorously, the most forward of them showing their flower trusses. The plants are not large, being such as are best adapted for decorative purposes. They will each produce from ten to thirty trusses of flowers. They are in 7-inch pots; each of the branches ought now to be supported with a neat stick. Smaller plants propagated in the autumn will produce better trusses of bloom in 5-inch pots than if they were potted into those of a larger size.

Green fly has been detected on the young growths, and the house will be fumigated with tobacco smoke the first calm night. It is great waste of expensive material to fumigate hothouses in a gale of wind. Wetting the roof of the house with water from a syringe closes many of the laps on the glass. Remove all decaying flowers at once; brush the stages at least once a-week; study cleanliness and neat arrangement, avoiding overcrowding the plants, which to the initiated is always suspicious, as it is generally a cloak to hide badly cultivated plants.

Plants that are no longer required in the house, such as Roses, Deutzias, and, indeed, any flowering shrubs that have been forced, though hardy enough in themselves, must not be placed out of doors, or the young growths will be injured. If no cool glass house is available for them they ought to be sheltered from cold winds and frost by a canvas house, turf pit, or some similar arrangement. When cold east winds prevail with sunshine it is best to admit but little air, rather using the shading to keep down the temperature.

Summer-flowering, New Holland, and other hardwooded plants should be examined daily. They must not be crowded with the more rapid-growing softwooded subjects, and particular care is required in applying water at the roots.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

JERSEY.—May 5th, Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.
BATH.—May 12th, September 1st and 2nd. Mr. B. Pearson, 13, Milsom Street, Sec.
CRYSTAL PALACE COMPANY.—Flower Show, May 29th; Rose Show, June 19th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.
COVENTRY.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.
LEEDS.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.
BURTON-UPON-TRENT.—June 16th. Mr. Wm. Shave, Bond Street, Sec.
GLASGOW.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.
FAREHAM.—June 23rd. Mr. H Smith, Sec.
EXETER (Rose Show).—June 25th. Mr. J. N. Gray, Queen Street Chambers, Hon. Sec.
WISBEACH.—June 30th. Mr. C. Parker, Hon. Sec.
MAIDSTONE.—(Roses), June 30th, at Vinters Park. H. Benstead, Esq., Hon Sec., Rose Club, Mill Street, Maidstone.
SPALDING.—July 1st and 2nd. Mr. G. F. Barrell, Hon. Sec.
SOUTHGATE.—July 3rd. John Miles, Esq., Hon. Sec., Southgate, N.
DURHAM AND NORTHUMBERLAND.—To be held at Elswick Park, July 7th and 8th. Mr. R. Ravely, Sec.
NOTTINGHAM.—Rose Show, &c., July 9th and 10th. Apply to Alfred Kirk, Municipal Offices, Nottingham.
TONBRIDGE.—July 14th. Mr. W. Blair, Free Press Office, Hon. Sec.
WIMBLEDON.—July 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Sunnyside, Wimbledon, Hon. Sec.
DARLINGTON.—July 16th, at Southend. William Hodgson, Sec.
BRECON.—July 22nd. Mr. W. J. Roberts, Sec.
CLECKHEATON.—July 24th. Mr. S. H. Williamson, Hon. Sec.
PRESTON.—July 28th and 29th. Mr. W. Troughton, 4, Church Street, Hon. Sec.
SOUTHAMPTON.—July 31st and August 2nd. Mr. C. S. Fuidge, 32, York Street, Lower Avenue, Sec.
RAMSGATE.—August 25th. C. D. Smith, Esq., 8, Marine Terrace, Margate, Hon. Sec.
DUNDEE.—August 26th, 27th, and 28th. Mr. R. McKelvie, 51, Reform Street, Sec.
SOUTH OF SCOTLAND.—To be held at Dumfries, September 3rd. Mr. J. Blount Dinwiddie, 11, Buccleuch Street, Dumfries, Hon. Sec.

TRADE CATALOGUES RECEIVED.

J. Wills, F.R.H.S., Onslow Crescent, South Kensington.—*Catalogue of New and Choice Stove and Greenhouse Plants.*

C. Van Geert, Rue de la Province, Antwerp.—*Hardy Trees and Shrubs.*

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Strawberries Cankered (*Head Gardener*).—Trench the ground and manure liberally with charred refuse and bone dust.

Pears' Blossom Buds on Leading Shoots (*I. S.*).—This is not an uncommon occurrence, and cannot be prevented; leaf buds will start further down on the young wood, and must be trained in the same place that the leading buds would have been trained. We have seen walls 14 feet high furnished from the base to the summit with trees trained as yours are, but they were on the Pear stock. The Quince stock is used when dwarf trees are required; but even on the dwarf stock the same height may be attained.

Jerusalem Artichokes (*H. T.*).—Plant at once fully 2 inches deeper than usual, and if towards the autumn the ground cracks by the swelling of the tubers surround the stems with soil. Exposure of the tubers to light and air is, we believe, the main cause of their not boiling tender.

Roses for Bleak Heavy Soil (*Amateur*).—Your only chance seems to have strong sorts on seedling Briar, but you must not expect really good Roses under the conditions mentioned. We recommend Charles Lefebvre, John Hopper, Madame Clemence Joigneaux, Sénateur Vaisse, Boule de Neige, Gloire de Dijon, Général Jacqueminot, Fisher Holmes, Maréchal Vaillant, Baroness Rothschild, Abel Grand, Countess of Oxford, Victor Verdier, Madame Victor Verdier, Madame Eugénie Verdier.

Aucuba Berries (*H. H. B.*).—Your old Aucuba did not produce berries because it was a female plant; so soon as you planted a male plant near, fertility became a matter of course. No Aucuba berries were produced in this country until Mr. Fortune brought a male plant from Japan a few years since.

Honey Locust Seed (*J. Grant*).—Apply to the seedsmen who advertise in our columns.

Apple (*J. E.*).—A variety to precede the Blenheim Orange—that is, to be ripe in September, you may grow the Wormsley Pippin.

Name of Grafton (*A Gardener*).—We do not think the name originated from any practice in your craft. The sign of "Grafton" the chronicler and publisher in Elizabeth's reign was a *graft* issuing from a tun; and Stowe, his rival chronicler, satirically observed that it was "the noise of an empty *tun* and an unfruitful *graft*." Grafton retorted that Stowe's Chronicle was composed of "lyes foolishly *stowed* together."

Ink for Zinc Labels (*E. G.*).—Make a saturated solution of sulphate of copper in gum water. Write with a quill pen. When quite dry give the labels a coat of white hard varnish, the labels being slightly warmed before application.—(*English Mechanic.*)

Flowers for Button Holes (*A Beginner*).—Amongst forced flowers—Lily of the Valley, Pinks, Tree Carnations, Bouvardias, Spiræa japonica, and Roses are suitable; also Gardenias, Ericas, Epacrises, Heliotropes, Lucnlia gratissima, Rogiera gratissima, Burchellia capensis, Clerodendron Balfouri, Eranthemum pulchellum, Eucharis amazonica, Euphorbia jacquiniæflora, E. splendens, Hoya carnosa, H. bella, Ixora acuminata, I. javanica floribunda, I. amabilis, Jasminum gracile, J. Sambac flore-pleno, Pancratium fragrans, Pentas kermesina, Rondeletia speciosa major, Stephanotis floribunda, Tabernæmontana coronaria flore-pleno; the last are stove plants. The following greenhouse plants are useful:—Adenandra fragrans, Bouvardia aforenamed, Camellias, Citrus (Orange), Cyclamen persicum, Daphne indica alba and rubra, Dracophyllum gracile, Habrothamnus aurantiacum, H. fascicularis, Jasminum grandiflorum, Lantana vars., Mandevilla suaveolens, Myrtles, Pergularia odoratissima, Pelargoniums, especially the double-flowered, Pimelea decussata, P. spectabilis rosea, Plumbago capensis, Polygala oppositifolia, Polygala Dalmaisiana, Primula cortusoides amœna and vars. alba, grandiflora; Rhododendron fragrantissima, Jasminiflorum, Prince of Wales, and Princess Royal, Rhyncospermum jasminoides, Statice profusa, double Primula sinensis, the double varieties of Azalea. There are also Roman Hyacinths, Narcissus, Tuberose, and Violets. There is no work on "forcing flowers."

Surplus Seed (*Idem*).—To mix old with new seed is not honourable—nay, it is adulteration, an imposition upon purchasers, and one that cannot be too severely censured. New seed germinates more surely and strongly than old, but we should not, nevertheless, destroy old seed until we had tested its growing quality, and if that proves equal to new seed, then feel justified in using it.

Cucumber House (*T. H.*).—Place the plants 2 feet 6 inches apart, or have five plants in each of your beds. For the Cucumbers a lighter description of soil is required than for Melons, light turfy loam for the former, and strong loam for the Melons, with a fifth of manure intermixed, or if the loam be rich omit the manure. The wires are best secured to the roof by an angle iron at each end, guide irons at about every 3 feet or beneath every rafter, the angle iron secured to the ends by bolts, and the guide bars at the top and bottom, with holders screwed into the rafters to have them the proper distance from the glass, and all to be pierced with holes for the wires to pass through. Something of the kind you want is given in the Journal for January 28th, this year, page 70.

Rose House (*F. E.*).—If you have Roses upon the roof so as to cover it, the space beneath will be made too dark for the successful cultivation of dwarfs. One up each rafter would be a different thing to covering the roof, but even those ought not to have a greater spread than 12 to 15 inches, leaving a clear space between each of 2 to 2½ feet, which will admit of light to the dwarf plants. Cocoa-nut fibre refuse is not, unless thoroughly reduced, good for pot Roses, and in that state is a desirable addition.

Passiflora edulis (*Mrs. H.*).—It will succeed in a vinery if it can have light, but not beneath the shade of the Vines. The vinery we presume is heated sufficiently for the Grapes to ripen in July or August. The Passion Flower would be best planted out, and the foliage must have light, the shoots being trained at about the same distance from the glass as the Vines. The fruit will ripen about August. The new fruit from Japan is a kind of Quince, and is said to make an excellent conserve.

Hardiness of Primulas (*Hawkshead*).—All the Primulas you name are hardy, but not as border plants, for many of them are alpine, and require the treatment of alpines, having the shelter of rock from drought in summer and wet in winter. We think yours have gone off from damp, and the pots not being plunged their roots may have been destroyed. The atmosphere also may have been too close, which is pernicious.

Mushroom Bed (*A Subscriber*).—Make the bed of fresh horse droppings, and not a "little firm" but very hard, the firmer the better, and about a foot deep. We like the droppings better when they have a small quantity of short litter, but this is not material for so small a bed. The droppings ought not to be wet, but be kept under cover. In about a week the heat will be at its highest; spawn it when it is reduced to 75° at 2 inches deep, and at this depth put in the spawn, pieces about 1½ to 2 inches square, and 9 inches apart, and cover-up, beating firmly. In about a week you may earth the bed 2 inches thick of good loam, and beat very firm. In six weeks you may expect Mushrooms to appear, but during that time the bed is not to be watered, or not until they show, and then keep only just moist and regularly so. If they do not appear at the six weeks' end you may commence watering, but lightly at all times, yet keep moist, the extreme either way will destroy them.

Cyclamens (*Lilla*).—Your plants will bloom as usual next year by the following treatment: Water sufficiently to keep the foliage fresh, withholding the water as it shows signs of decay, yet when the plants are quite at rest do not permit the soil to become dust-dry. They will start into fresh growth towards the autumn, and must then be repotted, carefully removing a portion of old soil, and adding fresh. A cold frame is the best place for them, or they may be stood in a shady place out of doors in May.

Sparaxis and Ixias (*Anxious Inquirer*).—In last week's answers to correspondents you would see particulars of treatment. After flowering they are to be kept dry, and potted in September. When at rest they may be kept in the soil in any cool place.

Cyclamen persicum (*Idem*).—Keep the seedlings moist until they show indications of going to rest, when they may be placed in a cold frame or be planted-out in a bed in a sheltered open border, and they should not be watered, the moisture afforded by the soil being ample. In September, or earlier if they begin to grow, they should be taken up and potted, and placed in a frame, keeping rather close, and in October be removed to a greenhouse. If kept in pots in a frame see to watering occasionally, so as to keep the soil from becoming dust-dry, but avoid making it sodden. Repot when they are commencing growth, and do it without injury to the fresh rootlets.

Neapolitan Violets (*Idem*).—Divide the plants into as many parts as you can, preserving a little root to each division or sucker, and these plant out in good rich light soil in a shady border, a foot apart every way. Water well during dry weather. Keep all runners cut off as they appear, or if you want stock they may be layered; but the plants will not be so good for flowering as those which were not allowed runners. Remove with balls to a frame at the close of September, or they may be potted.

Solanum Capsicastrum (*J. W. L.*).—Cut the plants in now with a view to compactness, and keep rather dry until they are breaking freely, then turn out of the pots, reduce the ball, and return to the same size of pot; place in a pit, keeping rather close and moist, and in June put them outdoors in an open warm situation, housing in September, or grow-on in a cool airy light house. They are, however, much cleaner and healthier for an outdoor sojourn in summer.

Sparrows Eating Peas (*Idem*).—They will eat Peas a foot high, much more when 3 inches; and even a yard high we have known them eat the growing haulm. Dust them with quicklime, which will not injure the Peas, whilst it will keep off slugs, beetles, and other predatory vermin as well as the sparrows.

Geranium Leaves Dotted (*Old Subscriber*).—The traces of insects upon the leaves are those of thrips, which may be destroyed by fumigating with tobacco, choosing a calm evening, and having the foliage of the plants dry. The plants are suffering from the cold ungenial weather. Brighter and warmer weather will put them all right; but you must admit air earlier in the day so as to dry up any deposition of moisture on the leaves during the night, before the sun falls powerfully upon them.

Zonal Pelargoniums Dying (*R. B. T.*).—No cause other than that of a disorganisation of the plant's tissues can be assigned as the malady by which you lose your plants. It is common to all plants, and especially those in a high state of cultivation, and is mainly a consequence of the treatment being too liberal in the plant's early stages, which causes an imperfect development and undue vigour, and this results in disorganised tissue; the young growths suddenly blacken and shrivel, simply because the roots are inert, and the stem incapable of transmitting to them a sufficient supply of sap. There is no remedy other than less rich soil, more air, and a drier atmosphere.

Gas-heated Boiler.—In answer to "J. H.," p. 262, the size of my boiler is as follows:—Diameter, 14 inches; height, 4 inches at centre; and 3 inches at sides. The case is 15 inches diameter, height 16½ inches to bottom of flue, and 26 inches to top of flow pipe. I have no doubt but that it would heat 150 feet of 2-inch pipe sufficient to keep out any frost, as I could keep my house up to 48° during the severe weather without turning the gas fully on.—J. W.

Beetle Injuring Vine Shoots (*A. B.*).—It is the Pitch-coloured Weevil, Curculio picipes. Spread a sheet under the plants attacked, and go at night with a lantern and shake the plants. The weevils are then feeding, and will fall on the sheet.

Names of Plants (*G. S.*).—The Begonia is probably a hybrid. (*Edwin*).—Hypoestes sanguinolenta. (*A. B.*).—Sparmannia africana. (*F. B.*).—Bæckea virgata. (*P. W.*).—Hypoestes sanguinolenta. (*Mrs. Oliver*).—Hibbertia dentata. (*J. S.*).—2, Selaginella sp.; 3, Abutilon sp.; 4, Conoclinium ianthinum. (*W. T.*).—2, Ficus stipulata; 3, Gymnogramma calomelanos; 4, G. ochracea. (*W. J. W.*).—2, Aspidium angulare; 3, A. coriaceum. (*W. D.*).—Erica carnea, Early-flowering Heath. (*Fred. and L. M. H.*).—Erythronium dens-canis, Dog's-tooth Violet. The specific names allude to the shape and colour of the roots.

POULTRY, BEE, AND PIGEON CHRONICLE.

EGGS.

We have only to glance at the advertisements to see how great a trade goes on in egg-selling. It is perhaps the only business in which members of every rank of life can meet on the

same ground, consequently it thrives apace. Even in back yards of large cities we frequently find prize poultry kept, while in many localities nearly every villa garden has its portion wired off for the chickens. We rejoice to think that it is so, and that our feathered friends are daily being more appreciated. Notwithstanding the great number of poultry fanciers of the present day we often wonder where the purchasers of eggs can come from.

Many egg purchasers are, we believe, fanciers in embryo who, seeing week after week the names of successful exhibitors at our shows, go to an exhibition for the first time, and catching the fever inwardly, burn also to win prizes and ornament their sideboards with silver plate. Perhaps these good people think the cheapest way of winning poultry glory is to buy eggs from a great and successful exhibitor, and so they despatch a post-office order, and order a sitting of eggs. In due time they arrive and are placed under the hen, and many expect to obtain from the dozen eggs at least nine or ten birds as good as the vendor is in the habit of exhibiting. Perhaps they hatch only four or five, perhaps less, that is the first disappointment, and at once they imagine they have been swindled; still when these which they have hatched grow up, they are often sent to a show in the full hope of winning the silver cup—in fact, people think for a few shillings' worth of eggs to win cups and prizes. The birds go to the show and are beaten, or perhaps some friend says they are not worth sending; then comes disappointment number two, and with it epithets of the strongest nature are heaped on the unhappy vendor's head. These egg-purchasers buy in ignorance and are not genuine fanciers.

Many do not take into consideration that the exhibitors who win so much generally breed scores of birds either at home or at neighbouring cottages and farms from which they select their winning specimens, and that a small fortune is spent in their rearing. It is a lottery almost whether the dozen eggs Mr. Jones buys contain the egg to produce the best bird of the year or no; and even if Mr. Jones does draw the winning egg, whether he knows how to make the most of it in the way of feeding and management. We are able to testify to this from two cases in which we have been concerned. First, many years ago we saw some eggs advertised at 10*s*. 6*d*. the dozen; we sent for a sitting, and hatched one chicken, and that bird won something like five cups and twenty prizes. Secondly, we sold a dozen eggs for 15*s*., from which four were hatched; one of those turned out to be a celebrated hen. In this case the gentleman gave 1*s*. 3*d*. to us for the egg, and we purchased the hen back again for £15 15*s*. from him.

Egg-buying and egg-selling will always be, however, unsatisfactory between strangers. The purchaser always thinks the vendor is a swindler if he does not have at least half a dozen birds for his few shillings. We really do not wonder so many decline to sell eggs. We are repeatedly told by those who do not sell that they only refuse to do so from feeling it must be unsatisfactory to all parties.

Then we are often asked about the packing of eggs. Some write to us and say if the eggs had been packed in a box they would have hatched; others, if they had only been in a basket we should have had better success. A third party says the eggs should not have been in hay, and others that they should. Experience, though, seems to show us that hay, from its elastic property, is more suitable than bran or sawdust, as these are shaken close in the transit, and the eggs are disturbed and cracked. We think a wrapper first of strong soft paper and then wisps of hay round each egg should answer all purposes, and baskets or boxes may be used according to the distance they have to travel.

Egg-buying people, no doubt, think they only have to bear the misfortune of an unsuccessful sitting. They very likely think when the great exhibitors send eggs to each other success can somehow be insured. We can only say that last season we reckoned the chickens from bought eggs had cost us 22*s*. 6*d*. each by the time they were hatched. We know of one party who finds egg-purchasing answer. He makes a rule of buying £20 worth every season, and always goes again to those who used him best. This party hatches what eggs he can, and sells their produce. When all expenses of every kind were paid connected with the £20 worth of eggs this man cleared in 1873 £27 15*s*., and in 1874 £38 16*s*. 6*d*. Now this is all straightforward and pleasant, but as we wrote in another journal, from which article we have here taken many passages, there is one kind of egg-purchasing from which all would do well to steer clear. We heard of such a one only this time last year. This party purchased sittings of eggs from noted exhibitors, and then having waited three or four weeks wrote and said all the eggs were clear, and he would indeed be obliged if the seller would send a fresh lot, or even half a sitting, free. We know of an instance in which this was done, and it afterwards transpired that there were nine chickens walking about in this party's garden which were the produce of the first dozen eggs, and which were described as all clear, and about which the purchaser had written so piteously.

There is another point many are hazy about: the difference between rotten and clear eggs. Many think rotten eggs are unfertilised eggs, while it is the reverse. Clear eggs are those which have never had the germ developed in them. For instance, the eggs laid by hens running without a cock will be all clear, and as clear many days after being sat upon as the day when first placed under the hen. Rotten eggs are eggs in which the germ, after being placed under the hen, develops till being accidentally chilled becomes putrid.

In egg-purchasing there is always risk. We are entirely at the mercy of porters and railway officials whether the packages are thrown about or moved carefully; but on the other hand sittings which people have come and personally chosen from our egg drawers and carried away have not hatched so well as those sent by train at the mercy of railway officials to Ireland, Scotland, and Jersey.—W.

THE EXHIBITION DORKING.—No. 13.

BY T. C. BURNELL.

WHITE DORKINGS.

These are great favourites in all country places, their snowy plumage and coral combs never showing to greater advantage than when contrasting with the green of a country meadow. They do not do well, however, for a large town, as their bright plumage very soon becomes soiled.

Fig. 65.—Cuckoo Dorking Cock.

A White Dorking's comb must be rose-shaped (double), firmly fixed on the head, and without any tendency to lop on one side. A single comb is a disqualification, but is now rarely or never seen. The ear-lobe, as in all Dorkings, should be red, and the feet white. The legs and feet are frequently found of a pinkish tinge, but white is the proper colour for the leg of a Dorking. The colour of the feathers should be a bright spotless white, and it is here where the difficulty occurs, as so many birds show a yellow tinge in their plumage. Many birds will moult out white, but if exposed to the influence of the sun will rapidly turn yellow. The cocks especially will become yellow on the hackle and saddle, their feathers being brighter in colour are more prone to absorb the sun's rays. Some cocks will keep much purer in colour than others, and, for breeding, we must be careful to select birds with this peculiarity in addition to their possessing a good comb and all the Dorking characteristics. Yellow beaks and toe nails should be avoided, as clearly showing a cross.

White Dorkings are not very great favourites with the show community, owing to the great difficulty found in keeping them

white and clean enough for the show pen. As soon as the sun attains any power the cocks to be shown are better kept out of the sun, or their plumage will soon become tanned, but with every care white birds occasionally require washing before exhibition.

The simplest plan for washing fowls is to fill a large crockery-pan or tin vessel with about 8 inches depth of warm soft water, souse the bird well in it, and wash thoroughly with a soft sponge and white curd soap till the dirt is all out, then pour in fresh water and wash-out the soap, and remember that as long as any soap remains the feathers will never web properly. After rinsing thoroughly squeeze-out as much water as possible. The bird should be lightly and quickly dried with a soft Turkish towel, and then be placed on some clean straw to dry. Each bird should be placed in a separate basket before a bright fire or in the sun, and in about twelve hours they should be quite dry and beautifully white. Sour milk is a capital thing to remove sunburn—that is, if the yellow tinge is caused by the sun and is not natural to the feathers.

White fowls should not be allowed to eat maize, or, as I have before stated, it will be very difficult to keep the plumage white. The best dust-bath for them is a heap of white drift sand or road grit.

The eggs are generally white in colour, but Mr. Creaswell informs me that some birds of his well-known strain lay pink eggs, and these must certainly look very pretty on the breakfast-table. The chicks when hatched-out should be of a yellowish-white colour.

CUCKOO DORKINGS.

During the last two or three years these have advanced much in public favour. They have now a class allotted them at the Crystal Palace and at two or three of the other principal shows, and as several fanciers are taking them up we shall probably see more of them in future.

They are called Cuckoo Dorkings on account of their feathers being somewhat similar to those found on the breast of our summer visitor the Cuckoo; but they are also called Blue Dorkings. The term "speckled Dorking" is sometimes applied to them erroneously. They appear of a blue or dark blue colour, but on examination it will be found that every feather is evenly marked with broad bars of dark blue or dark grey, on a whitish-grey or light blue ground.

In breeding these birds many chickens will come so darkly marked as to be almost black; these must be discarded, as we must not forget the original blue-mottled breast of the Cuckoo, to which we have to breed. The chief point to look to in exhibiting them is, that the cock and hen are of the same shade of colour, and that both are evenly marked all over. Rose comba are correct in this variety. The principal faults in the cocks are yellow hackles and saddles. They are too commonly found with white in the sickle feathers. A perfect cock with a Cuckoo tail is a rarity, but as size is one of the principal points in a Dorking it will not do to sacrifice an otherwise good bird for this slight blemish.

The hens are really wonderful layers, in fact quite equal to Hamburghs; while, though for the table they do not reach the size of the Dark Dorking, their full breasts and juicy flesh, combined with very early maturity, render them most acceptable in the larder. They are decidedly a hardy breed.

In conclusion, I will mention what I consider are the proper classes to be given to Dorkings in a poultry-show schedule. If only two classes are given they should be for Dark Dorkings and for "Any other variety." If three classes are given they should be for Darks, Silver-Greys, and for Whites or Cuckoos. Many committees do not receive as many entries as they should do by classing the Silver-Greys with the Dark birds, the result being that the Silver-Grey birds are never entered in the class, for their defeat is certain. If there is only one class for Dorkings it is very rare to see anything but Darks, the result being that the Committee lose the Silver-Grey, White, and Cuckoo entries, which if three prizes were given would be sure to make good classes.

COMING POULTRY SHOWS.

Epworth (Lincolnshire).—This Society holds its Show on May 7th. The Committee will send the birds on to Otley for that Show, which is to be held on the 8th. The prizes are £1 and 10s., and the classes are only few, neither Cochins, Brahmas, or Dorkings being sub-divided. Polands have a class, and Game Bantams are well looked after. Entries close on April 24th. The fee is 3s. 6d. per pen.

Sunderland holds its first Exhibition on May 17th and 18th. We are glad to see the name of the Judge is announced—viz., Mr. Dixon of Bradford. The prizes are 30s. and 15s. Most of the breeds have classes. There are five £2 2s. cups. Surely it would be best to give the money in cash instead of plate, for a £2 2s. article can only be a poor one. They are given in addition to the prize money. We are delighted to see Malays have a class. Bantams must be favourites in Sunderland, they have six classes and two of the five cups. Entries close May 3rd, the fee being 4s. per pen.

Crowle holds its Show on June 1st. The schedule is in many ways good, but the classes want more breaking-up. Cochins of all colours have to compete together, which is absurd. Black Hamburghs have no class. We wonder at this, for they seem to fill the best of the Hamburgh classes very often. Muscovy Ducks have a class, which is a novelty. There are twenty-two Pigeon classes for single birds, and most breeds are provided for, Magpies, Swallows, and Archangels having classes. Poultry and Pigeons have twelve pieces of plate between them, in the shape of cups, tea-services, &c. Both poultry and Pigeons have a point cup. The entries close May 17th. The Judges are announced.

Portsmouth.—The Royal Counties meets at Portsmouth on June 15th to the 18th. This town truly is rich in poultry shows. This will make the third show within six months. The prizes are 30s., 20s., and 10s. in Dorkings, Brahmas, Cochins, and the Variety class. The other classes have 20s. and 10s. Cochins are again lumped together, and as this class was one of the best filled at Reading last season they most certainly should have been divided this year. Polands have two classes. We hope we shall find them better filled than last time. The Pigeons have seven classes, which are very badly allotted, Magpies having a class, and Trumpeters, while Jacobins, Pouters, Turbits, and Dragoons go without. The Judge is not announced, but we may generally rely on meeting our friend Mr. Baily officiating as Judge at this Society's meeting. The entry fee is 3s. 6d., and entries close on May 15th.—W.

Scarcity of Chickens this Year.—In my poultry book I find noted that last year at this time (March 30th) I had 130 chickens and this year only fifty-two, but I hope to have sixty more in a few days. I lost but one chicken last year, which the hen trod on, out of 176. This year I have lost two. I have good neighbours that supply me with broody hens. The difficulty has been with the eggs, which have hatched out badly in consequence of the cold weather.—P. Harris, *Diss*.

RUSSIAN TRUMPETERS.

I must take up my pen in defence of my especial favourite the Russian Trumpeter. Your able correspondent "Wiltshire Rector," whose opinions on the Dragoon controversy, by the way, are entirely in accordance with my own, says in his letter of April 1st, "Unfortunately the Foreign Trumpeters will not breed in England." Now I bought two pairs of imported Russian Trumpeters from a well-known dealer two years ago, and bred from them nine young birds that season, five of which are now alive, and hatched-out as many more, but having unfortunately no feeders the earlier nests died of cold. Far from what he states being the case, I find that when they do breed they do so freely; but the young birds are delicate and hard to survive the first moult; that over, they are in my experience as hardy as any other high fancy breed.

I am anxious not to leave your correspondent's remark unnoticed, as I look upon them as quite as well worth cultivation as any fancy Pigeon we have, not excepting the Pouter and Carrier, and fear that such an assertion if passed over might deter others from attempting to breed them.

I should be very glad if anyone would tell us where they really come from, and how they are fed and treated in their own country. Northern Russia is a large place, but that is all the information I have been able to obtain as to where they are bred.—John H. Hutchinson.

RUFFED GROUSE.

In your Journal of March 4th, 1875, I see the question of importing Ruffed Grouse has been raised. Perhaps as I reside in a country where they abound, a few remarks may not be thought out of place.

The woods and barrens of Nova Scotia are covered with berries of various kinds growing on plants and shrubs, and in the former, abundance of cones of the several species of fir: all these are food for the Grouse. The question of introducing them into Scotland would not be one of climate, strictly speaking, but of food suitable to their wants.

After the first fall of snow the greater number of these berries are covered, then the grouse becomes poisonous, being obliged to eat berries at other times avoided. Several cases of severe collapse with fainting fits have occurred, to my knowledge, to people who had eaten Grouse, particularly the back and legs, after midwinter. But I have never heard of a fatal case when a mustard emetic, followed by stimulants, was given in time.

From their habits of running and treeing on any alarm they seldom give a chance of a flying shot, and I doubt their being much appreciated by sportsmen at home. They are easily potted on the ground, or in trees, by those patient enough to watch for them, so the Halifax market is full of them in early winter at 1s. 6d. to 2s. per brace.

As they are very quaint pretty birds when strutting about, a few would be a pleasing addition to the game of a home park.—J. Sheldon Furlong, *Surgeon Major, Halifax, Nova Scotia.*

LONDON FANCY CANARIES.—No. 1.

Of all the varieties of the Canary none are more beautiful than the breed known as the London Fancy. They have not only an exceedingly silky, gay-coloured plumage, but the contrast of the rich-coloured body feathers and black wings and tail are very striking. They are compact in form, and require more art and skill at the hands of fanciers in the bringing of them ont than other kinds. In this instance nature is assisted by art. For years past pure-bred London Fancy Canaries have been mostly confined to very few breeders, chiefly those residing in and about the metropolis, from which the breed takes its name. As to when or how the breed derived that particular name the oldest inhabitant would be at a loss to say, as much so as to when or how the terms Norwich, Manchester Coppy, Yorkshire, Scotch Fancy, or other particular breeds, each and all of which have striking contrasts, were applied.

I am not Darwinian enough to determine the knotty point as to how the supposed natural law of selection, climate, interbreeding, or food, may have brought about the peculiar forms or shapes of the different breeds. But one thing is clear—various kinds of food with artificial means of casting the feathers will produce various shades of colour, but not any new colour. Frequent instances have been known of the London Fancy birds having been bred and moulted in other parts of England, but not with that success generally as in the hands of the London fanciers. As a rule the palm for exhibition birds has been mostly held by the London exhibitors. Still I have known exceptions, more especially of late years, and some of the most noted fanciers of London Fancy birds in and about the metropolis have sustained defeat, their conquerors being superb specimens from South Devon. I believe that a southern climate is conducive to the success in breeding and moulting of these birds.

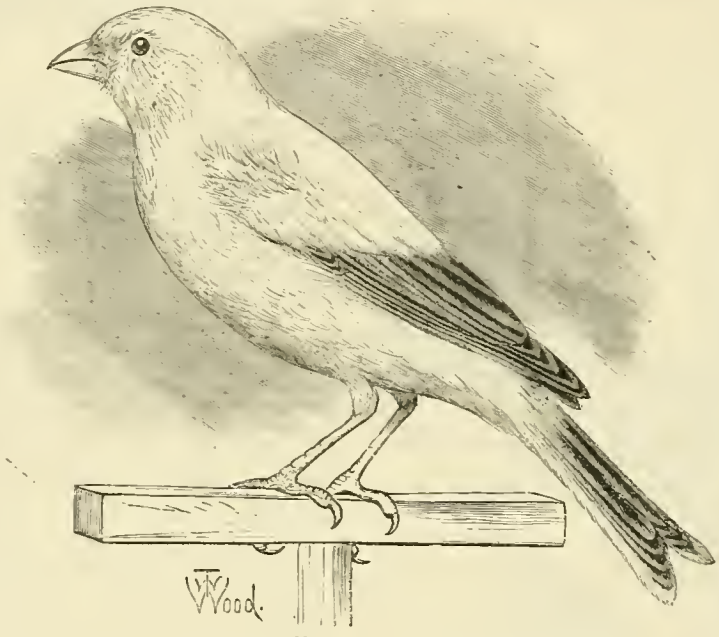

Fig. 66.—London fancy.

Some few years back I saw it asserted that there is a secret how to breed and moult the London Fancy Canaries, of which there are two kinds—Jonque and Mealy, and that such secret was held alone by the London breeders. This amused me much. In justice to the London Fancy breeders (several of whom I became acquainted with many years ago, but who have since departed from this world), I must say that when seeking for knowledge from them it was freely rendered. Now the supposed secret just amounts to this: that if one fancier is an adept at his work, and brings forth something striking to the eyes of other fanciers, those who are not proficient at their work conclude that there is a something of which they are ignorant.

London Fancy Canaries in their first or nestling feathers much resemble young Lizard birds, having dark plumage, excepting the cap, which is mostly clean or light in colour, but sometimes they are broken capped. Although resembling Lizards in first feathers, I consider them of an entirely distinct breed, but how brought about will no doubt remain a mystery.

Upon this point, however, there is some diversity of opinion. From one breeder of nearly half a century's experience I elicited the belief that the breed of the London Fancy was of a distinct kind. This I am inclined to believe. Another fancier of great experience and repute says, "With regard to the breed I cannot tell as to the origin of it, but it is supposed to have come from the Lizard Canaries." There is just this marked difference betwixt the moulting of a young London Fancy bird and a Lizard—the former when undergoing the moulting process in one of the cages adapted for the purpose (and upon which I shall remark hereafter), if properly moulted, will cast its entire dark body feathers, whereas the Lizard bird undergoing a similar process in the moulting cage will retain its dark, although improved, plumage throughout.

The drawing we publish in this number represents a London Fancy bird in its exhibition plumage, having a clean body and black wings and tail. The bird was exhibited by Messrs. J. & W. Waller, of Tabernacle Walk, Finsbury, London, who carried off both the first prizes in classes 17 and 18 at the recent Crystal Palace Show.—Geo. J. Barnesby.

WEATHER UNFAVOURABLE FOR BEES.

During the whole month of March the weather and wind have been so bitterly cold that the bees at Sale have seldom come out. I cannot remember a year in which the month of March was so unpropitious as the last one. In February the queens began to lay, and patches of brood could be found in almost all hives in this locality. I have seen no young bees yet, neither have we seen any bees carrying pollen on their legs, the weather being so cold. Whether the bees have succeeded in hatching all their brood during the cold weather or not, I have not had time to examine; if not, foul brood will be prevalent this season. In cold weather in early spring brood may be, and is sometimes, chilled to death, and it may perish from want of attention and nourishment. Bees are very helpless creatures in cold weather. Brood, chilled or starved to death, becomes foul, putrid, and pestilential in hives of bees. It is destructive of health and prosperity, and is incurable.

The bees of hives containing foul brood are invariably sitting more loosely amongst their combs than the bees of healthy hives. In examining hives at this season to find those most likely to be affected, I gently remove their covers and then turn the mouths of hives upwards so that I can see the bees amongst the combs. If the bees of some are more easily disturbed, and run more rapidly over their combs than the bees of others, I note them for further examination by the use of fustian smoke. In bar-frame hives the bars containing the brood can be taken out and examined. If small compact patches of brood be found they should be cut clean out, and pieces of empty comb fitted in their places. This is very easily done, and it is better to sacrifice some healthy brood amongst the foul than let one cell of foul brood remain in a hive. If cells of diseased brood be found widely spread over the combs we have evidence that the malady began last year, and should have been found out in the autumn.

All healthy hives will require kindly treatment now, and should be fed thrice a-week till the fruit blossoms appear. Half a pound of sugar is enough for three feeds a-week at present for a hive. By-and-by more will be needed if honey cannot be gathered by the bees. Both the numbers and activity of bees increase the consumption of food. The fact that bees have been greatly hindered in their work of breeding and development during the whole of last month should make apiarians endeavour now to stimulate and encourage them as much as possible, otherwise this year will be like the last one, very remarkable for late swarming.

Heavy mantles and warm muffs and woollen to the chins worn by ladies up to the present time, and winter overcoats on the backs of gentlemen, should teach bee-keepers that warm coverings for hives are necessary during cold springs like the present one. Bees cannot be too well and warmly covered

during the months of January, February, and March, if standing out of doors.—A. Pettigrew.

OUR NATIVE BEES.

Few persons have any idea that we have in these islands about 220 species, that they vary in size from one-and-a-half to about fourteen lines in length (I need hardly say a line is the twelfth part of an inch). Some are almost entirely destitute of pubescence, while others, as the bumble bees, are densely covered. The colour of their outer shell or case is generally a blackish brown, though sometimes quite a blue black; several are bronzy, while some are beautifully variegated with red, yellow, or white. Of course I am alluding to British species only. It is exclusively the female and neuter that collect the honey and pollen for the subsistence of the future young. The males do nothing but make themselves as happy as the sunshine will allow them, though no doubt, in sporting about from flower to flower, they are unconsciously making themselves useful by assisting nature in the distribution of pollen. This is collected in various ways. Some of them carry it on the shank of the hinder leg, some on the whole leg, which is densely covered with long hairs for the purpose. One large genus (Andrena) has a curled lock of hair at the base of the hind leg, beneath it; the back part of the thorax or middle portion of the body is generally more or less covered with longer or shorter pubescence, sometimes curled; and some (the social bumble and hive bees) collect into a basket, as it is called, formed by an expanded joint of the hind leg (tibia), round which is placed a row of stiff setæ, curved slightly inwards, and standing at nearly right angles to the outer surface of the leg. The hind legs of all those constructive bees which gather pollen on the leg are considerably thickened.

Another group collect on the belly, the plates of which are densely covered with stiff hairs for the purpose. The leaf-cutters and masons (Megachile and Osmia) are the principal ones of this division.

There is another large group of six genera, that have no special provision for carrying pollen; and they need none, because they do not collect any: they were named by the Rev. W. Kirby "Cuckoo bees" from the resemblance their habits bear to those of that bird; but more of them anon. The males in all are harmless insects, though some of them look far from it with their large forcipate mandibles; and when held in the fingers work their bodies about as if they meant stinging; but it is only the females and neuters that are furnished with that weapon. The males also differ in having thirteen joints to the antennæ, whereas the female has only twelve: the latter generally has that member subclavate and geniculated, the former usually more or less filiform; the male has seven segments in the abdomen, the female has six, and in one genus only (Anthidium) is smaller than the male. They are separated into two great divisions; in the first of these the tongue has two folds, and in the other three; the former are called Andrenidæ, or short-tongued; the latter Apidæ, or true bees. The Andrenidæ are again obtuse and acute tongued. There are two genera of the obtuse tongues, one of which (Colletes) bores its tunnels into the earth, dry bank or walls, and the other (Prosopis), a small black bee, bores into dead branches of brambles and rose trees—in fact, in any ready-made hole, or into dry banks. The hole being made or provided, they construct a cell, like a thimble in form, by lining the bottom of the hole with a secretion from the mouth, which dries and looks like goldbeaters' skin. Having collected sufficient honey and pollen, which is placed at the bottom of the cell, the insect lays an egg on the mass, closes the mouth of the cell, and proceeds to form a fresh one, joining to that already made. In this way she makes several of these cells, and then closes the mouth of the burrow, if in the earth, with soil. The obtuse tongue of these bees seems admirably adapted to plaster the cells with the secretion.—(*Hardwicke's Science Gossip.*)

HOW TO MAKE A BEE HIVE.

First, form the bottom board. Let it be 11 inches wide, by about 20 long, and about 1 inch thick. Put cleats on the under side to prevent warping. Plane the upper side smooth. Take a piece of hoop iron 11 inches long, seven-eighths wide; one-fourth inch from one edge, make six or eight holes through to drive nails. Put under the hoop iron a strip of veneering of hard wood, driving nails through this as well as hoop iron. Nail it across about an inch from the end or bottom board. The hoop iron should project over the place under it three-eighths of an inch. This will give a space to hook on the frame.

Next obtain material for frame. Let two pieces be about 11 inches long, one-half inch thick, and 1½ wide, measurements exact. Two pieces 18¾ inches long from inch boards, and three-eighths thick. Nail through the shortest pieces into the longest ones, just one-fourth inch from top and bottom. Nail firmly with finishing nails. Guides for straight combs should be in the top. The frame is held in position by a piece of hoop iron 3 inches long, bent into a right angle. Two holes are made through it to fasten it with nails to the lower corner of one end of the frame, and it is ready to hook under the hoop iron on the bottom board, and the frame will stand upright. A small nail dropped in loosely prevents unhooking. A half dozen will sit on the bottom board. A wider board can be made if wanted to make the hive larger, or two can be joined together. Directly under the centre, where the front end of the frame sets on the bottom board, an entrance can be made. Let it be cut out of the bottom boards half an inch in depth and three-fourths wide, extending 4 inches under each frame. The sides and top are made of half-inch boards, planed smoothly just the size of frames, with cleats nailed on each end to prevent warping. Put one on each side, and one on the top, and tie together with a stout rubber cord. It will hold everything snug, and the hive is done. It is convenient for our actual needs.

But as our readers may desire surplus honey in boxes as well as to extract, arrangements may be made for them. Have the bottom board wider than specified above, and a number more frames, according to the strength of the colony. Then make a number of small frames—be sure and have enough. The boards of which they are made need be only one-fourth inch in thickness, and 1½ inch in width, and the length just right to make a box when nailed together, 5 by 6 inches square. Six of these will go in one of these large frames. If they do not stay in properly a little wedge will hold them firmly. A guide can be put in the top of each.

As many frames as a colony can possibly need should be prepared; a part or all may be put into the hive with the others, and all shut up closely. If only two are put in let one be on each side outside of the others; they will need but little attention until full. But if bees are crowded outside, more should be put between the full combs of the hive. A number of these frames, with combs started in them, may be put together on the top of the hive, covered with a box—holes in the bottom of course—glass or boards on the ontside. These combs will be filled in less time if first put in the main hive and then removed to the top. When these little frames are put between the full combs of the hive they will need looking at once in five or six days, to see that brood is not started; in which case they should be removed and replaced with empty ones, the former to be set away until the brood is chilled, before they are put on the top, as maturing brood will darken the combs.—(*American Agriculturist.*)

Bath and West of England Society's Meeting at Croydon.—The show-yard will be opened to the public from ten o'clock in the morning until seven in the evening on Monday, May 31st, Tuesday, June 1st, Wednesday, June 2nd, and Thursday, June 3rd, and from nine o'clock in the morning until six in the evening on Friday, June 4th; care being taken that no cattle or other objects of interest shall be removed from the yard until after three o'clock on that day, and no poultry until five o'clock.

DEATH OF MR. FIRTH'S PRIZE SILVER-GREY RABBIT.

In a letter we have received Mr. Firth states—"I write to say that my young prize Silver-Grey buck died shortly after arriving home from the Hull Show. Before his death, and on my first opening the hamper, I at once wrote to Mr. A. Hudson, the Secretary of the Hull Show, stating that my Rabbit was fast sinking, and requesting particulars of its condition whilst at the Show and at his departure. This brought a brief note from Mr. Hudson, in which he only states that my 'two letters were to hand,' and that 'the contents of which' he had 'noted.'"

Not having received any further communication from Mr. Hudson, and having ascertained that the death was occasioned by some irritant poison, Mr. Firth concludes his letter to us by adding—"I hold the Committee of the Hull Show responsible for damages which I have sustained, and I shall certainly demand justice."

Drilling Glass.—Few who have not made the trial would credit with what facility glass may be perforated in any desired direction by means of a common drill applied in a proper manner. Small circular holes in glass sheets or cylinders are often required by the practical student, who does not care to have recourse to the "shop" for every little job. Supposing it to be desired to bore a hole through a glass sheet, such as might be employed in the construction of a plate electrical machine. A perfectly flat board should be provided, on which the glass may be rested, and a small depression made with a bradawl exactly in the centre. If a piece of boxcloth be placed over this board and fastened down tightly by tacks at the sides, all danger of breakage through inequality of surface will be removed. The position of the hole having been decided upon, the glazed surface of the glass (the skin) is grazed at that point by a scratch

or nick with a three-square file. The glass is then placed on the board with the marked spot exactly over the depression. A good steel drill fixed in the stock of a common bow or Archimedean drill, and of the dimensions suitable to the hole required, is to be dipped in oil of turpentine and then into fine emery. Placing the point of the drill over the marked spot, the operator proceeds to communicate rotary motion, without, however, exerting any considerable pressure, especially towards the end of the operation. It is by no means necessary that the drill should be excessively hard: even a copper drill, if duly supplied with emery and turpentine, will do the work effectually. Should it be desirable to produce apertures of considerable diameters, such as from a quarter of an inch upwards, it is advisable to make some little change in the arrangement. Thus the drill must be grasped both above and below by a "collar" to prevent any change of position while rotating, and the head of the drill should be weighted by means of a hinged lever, which is fixed by the hinge to any convenient spot and weighted at the other extremity, the head of the drill-stock supporting it in the centre. By this means an equable "feed" is secured. Instead of a steel drill, a brass or copper tube of the size of the aperture required is fastened to the stock, which, for this purpose, should work with a bow. By moistening the tube constantly with a solution of camphor in spirits of turpentine, and feeding with fine emery, a true and smooth aperture may be quickly cut.—(*English Mechanic.*)

OUR LETTER BOX.

Chickens Cramped (*R. H. T.*).—Your chickens die of cramp. If they are brought up on wooden, brick, or stone floors they are the cause. That will probably explain to you why the greenhouse did not afford a cure. If you will put the hens in a sheltered spot on the earth with plenty of dry road grit to scratch in, and feed well on bread and milk, chopped cooked meat, chopped egg, and curd, with some beer to drink, we think you will stay the cramp among them. If you cannot alter your flooring cover it some inches deep with grit or even sand.

Fowl House (*A Constant Reader*).—For eighteen Spangled Hamburghs your house may be 12 feet square and 10 or 12 feet high, 3 feet of brickwork from the floor, above that wood. The brickwork need only be 4½ inches, or 9 at the outside. It must be well ventilated under the roof. There should be glazed windows, one at each side. They should open in the summer. We find the Bridgewater tiles very good roofing. The door should face to the south or the west, and should be in a corner.

Golden Pheasant Hybrids (*Alpha*).—The instances of a Golden Pheasant crossing with any other bird are very rare. We know only of three instances, and they were all with common hen Pheasants. If you are disposed to try we should advise you to put the Golden cock Pheasant to a Golden or Silver Sebright Bantam hen. If you have leisure and convenience the best plan you can adopt is to set some Golden Pheasant eggs and some Sebright eggs under the same hen. Let them be brought up together and never separated. It will be a long process, as you cannot depend on the cock Pheasant to breed from till the second season.

Call Ducks (*T. H. T.*).—You may not have been cheated. It is probably a drake that has assumed hermaphroditic plumage, or sported in moulting. We have known a Duck assume the curly tail, and we have known a drake moult only half its plumage, failing to attain its nuptial plumage during the whole year. These vagaries are not very uncommon. Take for instance the hen-cock among Pheasants; the alteration of comb, hackle, and tail in common fowls. We once had a Widgeon that missed his male plumage in moulting, but grew a curling crest and mane.

Supply of Ducks' Eggs (*S. S.*).—There is little doubt that if all the Ducks' eggs are put under hens they will produce twenty-four ducklings, even allowing for some bad ones. Something depends on the breed. The Aylesburies are very good layers, and if they are kept we should expect more.

Judges of Pigeons at Hull.—In our report of the Hull Exhibition our reporter omitted to state that the Judges of Pigeons were Capt. Hill, Ealing, and F. Gresham, Esq., Sheffield.

Foreign Owl Pigeons.—"*Foreigner*" wishes to know the names of the prizetakers at York.

Canary (*M. H. F.*).—The substance is only mucus.

Canary Wheezing (*A Reader*).—Your bird is attacked with asthma, or in a slow consumption, not an uncommon matter with Canaries, especially when kept and suspended near the ceiling or in front of a window. Birds so kept in a room where fire or gas are used at certain periods, and the birds having to endure the chilling night air are so weakened as to be continually casting or throwing off their feathers, or otherwise attacked with disease. Whether your bird's illness has been brought about in a similar manner is not for us to say, but we know many instances where the lives of many good birds have been shortened through a want of knowledge in keeping them in good health. One very important point you inform us of, that of occasionally giving your Canary a "lump of sugar." For what reason? Is it because the bird utters a sound resembling the word "sweet," that you so indulge it with sugar? To a certainty you have done your pet more harm than good. We have often been pained when noticing birds in cages hung up high in heated rooms. If anyone wishes to try the experiment of breathing with difficulty let him elevate himself upon a chair or table, and then he will know the kind of air a bird has continually to endure. There is no wonder at birds being afflicted with panting and wheezing, for the air becomes poisonous and loses all elasticity. Under such circumstances disease is encouraged. The sugar not only impedes the breathing organs, thus producing the wheezing, but the digestive functions become interrupted. The appearance of the ruffled feathers and occasional distension are signs of nature labouring under difficulties. During the bird's illness you may discontinue the rape seed for a time and give Canary seed, linseed, and groats; administer one or two drops of castor oil, and supply a bread-and-milk diet for two or three days; afterwards let it have a free diet of watercress, small salad, and dandelion; now and then a little crushed biscuit, and half a teaspoonful of sherry wine in its water fountain, besides keeping the cage in a rusty nail, will tend to strengthen the sufferer. Stale bread soaked, the water afterwards freed from it, and half a dozen drops of cod-liver oil added as an occasional change. Supply grit, sand, and a small piece of salt in the place of the sugar; keep the bird free from draught, and the cage covered over during the night whilst the bird is so unwell.

Book (*T. P.*).—Mr. Pettigrew's second edition is just out, price 3*s.* 6*d.*

Best Hives (*F. J.*).—Your question is a difficult one to answer, especially as you do not say whether you want straw or wooden hives. Mr. Pettigrew, Sale, near Manchester, who is a most successful bee-keeper, finds large straw hives the most profitable. If you want such write to him for particulars. Mr. Abbott, of Hanwell, near London, N., will supply you with excellently made wooden bar-framed hives for cottagers at a very low rate. If you obtain a model you can doubtless have them made to suit your own wants from some village carpenter or basketmaker in your own neighbourhood. Experience will be your best guide as to what is the best hive for your own purposes. We ourselves do not believe in the existence of any "best" hive. This is the very best time in the year for the purchase of old stocks, but you must be quick about it now. Bees rarely fly beyond a radius of one and a half mile from home, although they have been traced much further to good pasturage.

Commencing Bee-keeping (*B. V. A. H.*).—If for profit and little trouble, use Woodbury's hive, and have a swarm of common bees put into it next month. To prevent swarming in a common hive is very difficult, and to a beginner almost hopeless.

REMARKS.

31st.—Rather dull morning, bright in the middle of the day; very little wind.

April 1st.—Dull morning, bright before noon, and a very pleasant day.

2nd.—Beautifully bright till 1 P.M. and all day, finer than any day for some weeks.

3rd.—Dull windy morning, bright about noon; windy at night.

4th.—Rain in the night and early morning, but fine before 9 A.M; very bright till 3 P.M., then dull; a little rain between 6 and 7, but a fine night.

5th.—Windy and wet early, but fine before 10 A.M., and very bright from that time to 5 P.M., then dull; but a fine starlit night, though windy.

6th.—Bright from 10 to 12.30, then a few drops of rain, and a sharp though short shower a short time after; but fine evening and night.

The temperature has risen about 4°, and the weather on three or four days been very bright and sunny, but the wind is still cold and trying.—G. J. Symons.

COVENT GARDEN MARKET.—April 7.

We have no change to report in the markets, the supply and demand being of the average condition for this season of the year. A few more Strawberries and some better Grapes can be obtained. English Pines are in very little request; the latest from St. Michael's being of excellent quality.

From observations taken near London during forty-three years, the average day temperature of the week is 58.8°; and its night temperature 36.5°.

GERANIUMS FOR BEDDING.

WHEN recommending lists of Geraniums it would be a very good thing if persons could also state what other sorts they had tried. For instance, "Age" recommends very strongly Warrior, Vesuvius, Lucius, Claude Lorraine, and Creed's Seedling. Although Vesuvius is spoken so highly of I cannot see its merits; it is, no doubt, hardy, tolerates bad treatment, and blooms freely for a certain time, but the truss is small. It does not endure sun and dry weather, and it seems to me very inferior to either Corsair, Jean Sisley, Star of Fire, Grand Duke, or Soleil. Claude Lorraine I long since discarded, but I never gave Lucius a fair trial. Creed's Seedling with me was never either a good yellow or a good green, and the flower only an inferior Tom Thumb. Maia, owing to the courtesy of the raiser, I shall be able to try this year, as he kindly sent me some cuttings in the autumn, and I have only lost one plant.

Again, when Mrs. Pollock is recommended as a Golden Tricolor, has "Age" tried Sophia Dumaresque, Lady Cullum, William Sanday, Macbeth, Edith Pearson, Queen of Tricolors, &c., against it? as, so satisfied am I of the superior merit of all those I have named, that Mrs. Pollock is no longer grown here, as not retaining its leaf-colour in hot sunny weather. William Sanday seems likely to be about the best bedder we have.

I had intended to have given a description of a few of the best of those on trial here last year, but have put it off till too late for this year, and hope that some of those who study the different kinds of bedding Geraniums will, at the end of this season, make out a list of the best. My impressions at present are in favour of the following:—

Dark Scarlet.—Edward Sutton, General Outram.

Scarlet.—Star of Fire, Corsair, Grand Duke, Soleil, Jean Sisley.

Crimson Scarlet.—Bayard, Vesta, Bonfire.

Crimson.—Mrs. Vincent, Charley Casbon.

Cerise.—Violet Hill, Lady Kirkland, Arthur Pearson.

Rose.—Rose Bradwardine.

Deep Pink.—Contessa Quarto, Mrs. Holden, Mrs. Ffytche, Pink Queen, Mrs. Musters.

Lighter Pink.—Master Christine, Mrs. Lowe, Mrs. Upton, Rose Rendatler.

Lilac Pink.—Amaranth, Florence Durand. Gloire de Corbenay is certainly one of the best of that section, but it is difficult to find a place for it in a set of beds.

I wish some one could raise another Lady Kirkland with a stiff flower stalk, there is no more continuous bloomer. It has the merit, too, of not seeding, and the trusses are large; but it has a very slender footstalk, and the trusses straggle about the bed.

The following seem to me the desiderata for a bedding Geranium—flowering section:—

1, Colour bright and decided.

2, Truss large; pip good size and substance, capable of standing sun and wind.

3, Footstalk firm and strong, not too long nor too dwarf.

4, The individual flowers on long stalks, so that the truss should not be too crowded.

5, Freedom of blooming.

6, Spreading habit of growth.

7, Foliage uniform in colour, not too much zoned; a bright clear green is much better, as a rule, than a horse-shoe.

8, Continuance and duration of bloom is more valuable than mere profusion at one time.

The Geranium which with me unites these qualities more than any other is Violet Hill. It is, however, very dwarf, and many persons discard it because it requires care and attention; and it will not succeed with an ordinary cold-frame treatment. Mrs. Lowe, as a light bright pink, is quite as good in its way.

It will be noticed by many that plants gradually acquire a dwarfer habit of growth the longer they are cultivated; many which were too strong and vigorous in their second and third year from the seedling state, as William Underwood for instance, often lose this vigorous growth and become more compact.

Amongst Tricolors I have already named the best. In the Bronzes I do not like either those that are too dark, as Black Douglas, or those that turn green, as Her Majesty, Beauty of Calderdale, or Beauty of Oulton. The best in point of colour are Crown Prince, Impératrice Eugénie, Reine Victoria, Marquis of Lorne, and Earl Rosslyn; but they all want good soil and generous treatment. I have not succeeded with any Silver Tricolor as yet.

Among the Whites I prefer May Queen, Flower of Spring, Miss Kingsbury, Castlemilk, Pearl, and Mrs. Lennox. Beaton's Variegated Nosegay did not succeed with me. Bijou is too upright in growth, and Alma is inferior to those named.

There is quite a plethora of good Pinks since Mr. Pearson of Chilwell sent out so good a batch in 1872; and it will be a difficult thing, I think, to decide between the merits of such sorts as Contessa Quarto, Mrs. Ffytche, Mrs. Holden, Miss Young, Miss Skipworth, Mrs. Augusta Miles, Mrs. Musters, &c. Of this we may be perfectly certain, that the older pink varieties, as Christine, Pink Perfection, Countess of Rosslyn, and some others, will have to give way.

I may say, in conclusion, that having tried a great number of pure Zonals for bedding, as Clipper, Dr. Lindley, Roi d'Italie, &c., I have quite come to the conclusion that no pure Zonal is so good as those that have some of the Nosegay blood in their veins, and that Stella and Black Dwarf, though perhaps now discarded, have done much to improve our bedding Geraniums; and as I look forward to the time when this rage for carpet bedding with formal cut patterns will again give way to the best stamp of flowering plants of each section, I still hope that our raisers of bedding plants will continue to

improve the quality of flowers as well as turn their attention to foliage.—C. P. P.

NOTES FROM MY GARDEN IN 1874.

GLADIOLUS.

"It is a long time," was the burden of a recent note, "since you have given us anything about the Gladiolus in the Journal." Well, it is: time runs on, many things crop up, and one forgets how long it is since one has written. Moreover, there is not now a great deal to say; and what I have to write may perhaps as well be written under this heading as under any other. And yet I am more perplexed than ever as to what to say about it. I believe it to be the most disappointing and perplexing flower we have to do with. I never had finer-looking beds for some months, never finer blooms, and yet at the time of lifting never more disease. "Hold!" I hear someone say; "don't discourage people and frighten them out of growing them." To this I cannot subscribe. Truth must be told, and no suppression of facts can be justifiable when we are writing on the merits or demerits of a flower. It is impossible to praise too highly the beauty, the variety of its colouring, and the grandeur of appearance of the Gladiolus. But all this must be weighted by its fatal facility to disease; and I know of more than one grower who says, "Year after year I determine to give it up, and yet notwithstanding my losses I cannot quite make up my mind to do so."

I had last year as usual three beds containing about four hundred bulbs. These were from the following sources: 1, The most considerable quantity my own saving; 2, a goodly number of imported bulbs; 3, a few of Mr. Kelway's highest-priced roots; and 4, a few from my friend Mr. Banks. Amongst the French roots were the set of eighteen sent out by M. Souchet, and of these I found the following to be the best:—

De Michel.—A large and very long spike; rose slightly veined with lilac, and the throat lined with dark carmine.

Le Vesuve.—A magnificent colour, fiery red, large and brilliant, evidently of the Meyerbeer type. I look upon this as a grand flower, although my friend Mr. Banks says that Meyerbeer will be a more lasting flower.

Murillo.—Another very fine spike; cherry red, light centre, all the petals lined with white, with large white spot on the lower petals. A grand variety.

Psyche.—Very large spike of light satiny rose; lower petals darker rose. This variety was considered by M. Souchet the best of the year, but it is not so to our English taste.

These were the best four. Of the others I rather liked Sirene, a fine spike, light salmon rose; Ambroise Verschaffelt, light rose, flamed red. Albion and L'Unique Violet never did anything; indeed the latter never appeared above ground. Merveille was fine but not remarkable, and of the others I can give no very good account. From Mr. Kelway I had Victory, Lady Bridport, Medina, and Ball of Fire, and am sorry to say I was disappointed in them. There must be something in his way of growing them, for I had seen them very fine with him; with me they were the reverse of that.

In former years I had advocated the use of charcoal, considering that it might act as a preventive of disease. I regret to say that such an idea has been entirely dispelled by the experience of the past year. In my three beds I had some treated with charcoal and others with sand, but I found no difference in the attacks of the disease. The English-raised seedlings were attacked by it, although it is stated by some that they are of a hardier constitution. In fact it is one of those mysterious disorders about which we are entirely in the dark. I saw it last year everywhere. My friend Mr. Banks suffered most severely. I saw it extensively in Somersetshire, and a little of it at Fontainebleau, while Lord Hawke wrote to me that he felt thoroughly disheartened by its prevalence in his best beds. No vegetable physiologists seem to be able to tell us what it is and what its remedy is any more than they can about the Potato disease. Indeed the thought has struck me whether they may not be analogous; and if so, may it not be that as unquestionably the autumn rains have in some mysterious way to do with the prevalence of the disease amongst the one, they may not have also in the other? We cannot lift our Gladioluses early as we can our Potatoes, but it might be worth while to try on a small scale whether the covering of a bed, and so preventing it receiving the autumn rains, might preserve the bulbs from disease. The fact that the French growers do not suffer so much from it would rather bear this out. Their autumns—autumns in which the rich produce of their vineyards are gathered in—must be, and indeed we know are, much drier than ours. At any rate it might be worth consideration, and on a small scale I shall try the experiment this year; for while it would be hopeless for the man who grows his tens of thousands of bulbs to attempt anything of this kind, the amateur who is obliged to be satisfied, as I am, with a few hundreds, may well try to do something to save his most valuable bulbs at least from destruction.

I am disposed to think that mulching is more serviceable than I once thought it was; and at Mr. Kelway's I saw the beds very thickly coated with manure, and we all know what spikes he is able to produce.

We have now but one exhibition where we may hope to see them properly represented in the metropolis—that to be held at the Alexandra Park by the Metropolitan Floral Society in the latter part of August. The Crystal Palace is too late except for monster growers like Mr. Kelway, and the miserable amount of the prizes at South Kensington will preclude amateurs from competing. I hope, then, at the Alexandra Park, where a large sum is offered for them, there will be a good competition and a grand display.—D., *Deal.*

PEARS.

My experience is that Pears vary very much according to soil, climate, and the kind of stock on which they are grafted. Some which are excellent on the Quince are worthless on the Pear stock, and *vice versâ*. They also vary much according to the season. Some sorts do best in a dry season, others in a wet one; so that a Pear which may be first-rate one year will be only second or third-rate another year. This last year, for instance, I found the following sorts, which are usually excellent, were only second-rate—Fondante d'Automne, Beurré Bachelier, Joséphine de Malines, and Easter Beurré, which last was very much spotted; whereas the season evidently suited other varieties—*e.g.*, Conseiller de la Cour, Baronne de Mello, Doyenné du Comice, Winter Nelis, and Bergamotte Esperen, which last is only just over.

Last year I fruited just sixty varieties of Pear. Of these there are only five now remaining in the fruit-room—Catillac, Uvedale's St. Germain, Verulam, Beurré de Rance, and Bezi Mai. This last was sent out as an eating Pear, and perhaps it may prove eatable once in half a century; but it is a very good bearer and an excellent stewing Pear, and will keep till July, or even longer if required; but out of these sixty varieties, to my mind there was no question as to the one which was first in excellence. It was a Pear which came to me from France, with the label partially obliterated; it was the "Fondante de C——." So far I could make it out, but no further, and accordingly I called it Fondante de Comice; but I do not see a Pear of that name on any list, and the Pear itself answered to the description both in appearance and season of the "Fondante de Charneu," with its six *alias* names in Dr. Hogg's "Fruit Manual," page 291. It is a variety which, as far as I can ascertain, is unknown in this district, but perhaps some of your correspondents from other parts can give some information about it. This last season it was certainly the best of my sixty varieties, and I think the best Pear I ever met with.

As I sometimes see inquiries about "fruit-rooms," my experience on this point may be of use to some of your readers. I had a small wooden barn about 14 by 10 feet. I had it lined with half-inch deal boards, and filled the space between the two boardings (about 6 inches) with sawdust. This has answered very well, and the thermometer was never below freezing point in the coldest nights of last winter, and the fruit has kept perfectly well till now.—William Lea, *Droitwich.*

TROPÆOLUM CANARIENSE.

This useful and very pretty climber, growing to the height of from 10 to 12 feet, and producing hundreds of canary-yellow flowers, being a half-hardy annual, requires to be raised from seed under glass. The most successful way is to sow the seed from the middle of March to the present time in pots, pans, or boxes. When large enough the seedlings may be potted off into pots varying in size from 3 to 6 inches. Three plants might with advantage be put into 6-inch pots, trained on stakes, and gradually hardened off in any cold frame or other protection, when they may be planted out in many suitable ways. They may be trained on pillars, porches, or any kind of fancy wood or wire frames.

Last summer I saw a very good effect produced with this

Tropæolum on a serpentine border 2 feet wide and about 60 yards long. Amongst other plants in the border were six Irish Yews 7 feet high; on each of these were trained three plants of this Tropæolum, and although exposed to severe gales of wind, it looked very pretty, and was admired by many.—William Laurie.

AURICULAS.

April, as the derivation of its very name imports, is truly the month that opens the year. To the florist it is the entrance into bloom of his first-born favourite—the Auricula; the flower which, let me confess, is with me the heiress, the princess royal of my floral love.

From this time forth till brown October comes, those of us who grow "the round" of florists' flowers have now no break in our Daisy chain. No two links in this succession are alike; and although I know not one flower in the world that stays long enough to tire us, still there is rare richness and an intended refreshment in complete changes. The Auricula, Polyanthus, Tulip, Ranunculus, Pink, Rose, Carnation, and Picotee, which form the length of the lovely chain with me, leave me naught to envy though much to admire in other gardens.

I have no "popular" flowers except the best of the Roses in fat beds (they will lie in any depth of "feathers," these luxurious beauties), all my non-florist flowers being quaint herbaceous oddities—plants that have quietly withdrawn themselves from the glare of gardens *à la mode*, but take kindly to the shelter of an old place like mine, where they seem to know they are welcome for their own strange beauty's sake, and are not rated at the common estimate of the world for how much of "effect" they are worth. But I must keep to the objects for which I write.

One is to apprise all interested in the culture of the Auricula that the National Auricula Society's next show will be held on April 27th (Tuesday), in Manchester, and in conjunction with the Spring Exhibition of the Manchester Botanical Council, to whom are due the hearty thanks of florists for the encouragement given to the public exhibitions of florist flowers. As a rule these have of late been virtually private, being held among the growers of a neighbourhood and their friends.

Another matter on which I would say a word is the question raised lately by "G. S.," whether an Auricula with a tall rootless stem could be cut down with safety. It is a constant practice of my own to do so, and the operation is perfectly safe. Not only is there no danger to fear, but considerable profit to expect. Some sorts are fond of making long stems—*e.g.*, Catherina, Lord Lorne, and Mrs. Sturrock; but a collection should not be allowed to run into this habit. Cut off your rootless top, and rub the wounded surfaces with powdered charcoal. Pot this top firmly—very firmly, and keep the soil but moderately moist; cover it with a broken wineglass or a cheap tumbler, or pot the cut piece low enough for a square of glass to lie over the pot top. See that no wet lodges in your plant, and keeping it thus close and cool you may justly expect it to prosper. It can root from any ring on the stem from which a leaf has sprung, and when the heart shows signs of growing-out admit air freely. The old topless but rooted stem can hardly fail to break some dormant eyes, and so you gain at both ends. I will here state that most of my fine stock of Page's Champion has been won by my twice beheading plants, striking the rootless head, and then receiving that back as a fine short-necked plant while the old "carrot" has gone on, throwing offsets at the eyes that were dormant before. I have plants at this moment undergoing this little device. The only notable failure I can recall was with a plant of Jupiter—my only one, and I cut it because of unsoundness, hoping a little at the top would come round, but I could not save it. It is wonderful how this plan of striking an Auricula top will answer, and if you can save a single ring of stem you are not past hope with it.

I have had pieces like this strike root out of the very leaves near their base, and I have a gem of a seedling now thriving after that narrow escape. Again, I have cut rootless heads off in the autumn, kept them under a small glass, had them root during the winter, and go on with the rest in spring, the same as offsets. There is a time for all things, and when "G. S." wrote his query the spring foliage of Auriculas was so far advanced that a rootless top would suffer more than if taken off in quieter times. Often a plant makes two hearts after the bloom, and a two-headed plant cannot take both trusses to an exhibition. Not choosing to wait till both heads are rooted, I save a year by sharply cutting the whole stem down, allowing each head half the roots, rubbing all wounds with powdered charcoal. I have seen Auriculas beheaded and struck, and the old stem, or carrot, fairly quartered, and all the quarters giving out eyes.

It may shock my friend "D., *Deal*," to hear of Auriculas being so knocked about. He will handle his with tenderer touch; but a friendly correspondent of mine, the Rev. Mr. Tymons, seems to side with me. It is no new thing I speak of, but a practice pursued by growers with less advantages than I have. I am thinking of my friend Benjamin Simonite of Sheffield among others, who in the very thick of that black, and bleak, and dismal air grows the Auricula right well, besides the Carnation and Picotee. It was of him bringing flowers in fine order to an exhibition that a friend once said, "Here comes the man that grows his flowers up engine-house chimneys!"

Talking of exhibitions and meetings reminds us always of those who will not be there next time—of the friends we have lost between while. We shall not see Robin Lancashire with us any more. He is one more genuine florist of the old school gone; his age 77; his Auriculas the last flower in his possession as with so many old florists. The sort known as Lancashire Hero was raised by him; it is a name familiar as a household word among growers, and we shall grow it a long time yet.—F. D. Horner, *Kirkby Malzeard, Ripon.*

THE ORCHID-HUNTER IN BURMAH.—No. 3.

Pegu and its neighbourhood are so rich in many fine Orchids, which are not so abundant in any other part of Burmah, that before continuing a description of the various Dendrobia it may not be uninteresting to enlarge on the different Orchids found in that district. By placing a description of these plants side by side, and giving a description of the climate in which they all grow, a fair idea may be arrived at of the treatment required to grow them to perfection.

Pegu is probably the hottest part of Burmah, the average temperature during the day in the shade from June to the end of March being 80°, and in April and May 90°. The variation of temperature during the day is not great—about 5° more or less. The nights are comparatively cool, the heat being 10° less than during the day. There are a few showers in April, and from the end of May to the beginning of October a very heavy rainfall, averaging 150 inches during the season.

The Orchids of Pegu are common to the lower parts of Burmah, and are pretty freely scattered throughout the different districts; the Orchids of Upper Burmah, and again of the mountains of Burmah, being quite distinct in character, and in the circumstances in which they are placed by Nature.

Vanda teres is the Orchid of all others that most strikes the eye in travelling through Pegu. When in flower the way in which it lights up the trees on which it grows is very remarkable, making the trees look as if they themselves were in full bloom. This plant is almost invariably found growing on Lagerstromia reginæ, a large tree, bearing beautiful mauve flowers, which are generally out of blossom by the time the epiphytes inhabiting it come into bloom. This tree has very smooth branches, to which the roots of the Vanda cling. The stems of Vanda teres are cylindrical, frequently 30 feet long, often branching, and throwing these branches into the air well above the trees on which they grow, so that when they flower in midsummer the whole top of the tree is a mass of blossom. The foliage is terete, rigid, colour dark green, more like the foliage of the Luisias, and entirely distinct from that characteristic of the other Vandas, with the exception of Vanda teres Andersoni, which is a variety of Vanda teres, and Vanda Hookeri. It bears splendid spikes of flowers, frequently ten flowers on a stem. The flower is large, 3 inches across, varying from rosy red to pure white tinged with yellow. If Vanda teres can only find a dead or leafless tree of Lagerstromia reginæ to grow on it is then indeed in its glory; it embraces the tree with its tendril roots like a beautiful creeper, completely covering the stems, and forming a glorious and gigantic bush of flowers.

Success in the cultivation of this plant in England has been limited, and perhaps from the foregoing description the horticulturist may gain a few suggestive facts: First, that the roots of this plant like the cleanest and smoothest of barks to grow on; secondly, that the plant loves the greatest amount of light; and lastly, that the more sun and heat it has the more freely it grows and flowers. Cultivators in England generally con-

sider this a shy-flowering plant. In cultivation abroad it grows well on a smooth pole, the pole having plenty of surface for the roots to attach themselves to. The roots are wonderfully numerous in good healthy plants, so that a good surface for them to grow on is a great requisite. More specimen plants of this grand Orchid would be seen if the importers sent larger plants home, and sent them at the beginning instead of the end of the resting season.

Vanda teres Andersoni is also found about twenty-five miles north-east of Pegu, it is identical in growth with V. teres, but smaller in habit. It bears similar flowers, and grows on the Mimosa trees. It is a rare plant in Burmah, but said to be common in some parts of India.

A variety of Vanda gigantea grows here in enormous masses. It bears spikes of yellow flowers of thick waxy substance, the petals being marked across with bars of red. Unlike the other Vandas, which all like the light, this plant appears to attach itself to trees having a heavy foliage. It is beautiful when in full flower in June and has a smell of Apples, and is commonly known in Burmah as the Apple-scented Vanda. It would not be acceptable to the general cultivator of these plants in England, as only those having enormous houses could grow it satisfactorily. To those who have it, it is worth noting that it flowers and grows freely in a shady place. Although growing on shade-giving trees this plant is always found on trees in the open country, generally on trees growing on swampy ground.

In the same swamps, on the yellow Mimosa tree, flourishes a very pretty Camarotis—Camarotis pallida, with scandent habit and hard blunt leaves bearing racemes of yellow flowers. Those who know Camarotis purpurea can form a very good idea of C. pallida, the two being almost identical in habit. It is very abundant, and flowers during the early rains. Fine specimens of it are well worth growing in our Orchid houses in England. It takes up little room and likes plenty of heat and moisture, and should be grown on cross-bars of teak with a little moss. It has a most distinct season of rest; but as the leaves shrivel during the dry season, it is probable that in home cultivation it would improve the plant to give it sufficient water to prevent it from shrivelling. Camarotis purpurea has been found in this district, but it is exceedingly rare in Lower Burmah. It is said to abound in Arracan and in the Delta of the Ganges; it is a well-known plant bearing rose-coloured flowers. The same remarks regarding cultivation apply to it as apply to Camarotis pallida. These varieties of Camarotis are found clinging to the outside twigs of the trees, and are rarely found growing on any branches thicker than a small cane.

On the same trees as the Camarotis, and in great abundance, is found a very pretty pink Sarcanthus, a variety of Sarcanthus filiformis. It has terete leaves on opposite sides of the stem, which is cylindrical. The stems and foliage are alike rosy purple in colour, the racemes of flowers being pink. It is a very elegant plant most interesting to the amateur, but probably of not sufficient character to induce the importer to send more than a few stray plants of it home. It grows best on cross-bars of teak, under the same treatment as that suggested for growing Camarotis.—E. S. B.

ROSES.

"Cornubia" accuses me of omitting Prince Camille de Rohan, or, as many call it, Camille de Rohan. I have never to the best of my recollection omitted it from my selections. If I have done so, it has been a lapsus. I thank Mr. Peach for saying (page 271) "I must acquit Mr. Radclyffe of never having recommended Prince Camille de Rohan, as I remember at one time it used to be a favourite." Now turn to October 1st, 1874, and you will see that I and twelve other amateurs included it in the fifty Roses of the election, and seven others omitted it. The following amateurs named it:—Mr. J. Ellis (39), Mr. R. Davis (47), Mr. Tapner (36), Mr. Quennel (34), the Rev. G. Arkwright (17), Mr. Barrel (35), the Rev. Alan Cheales (42), the Rev. J. B. Camm (47), Mr. R. W. Beachey (15), the Rev. H. Dombrain (40), Mr. R. Robson (45), the Rev. R. N. Milford (22), the Rev. W. F. Radclyffe (26). The other amateurs, six in number, who did not elect it, were Mr. James Mayo, the Rev. C. P. Peach, the Rev. E. N. Pochin, Mr. John Scott, Mr. J. Hinton, Mr. J. F. Curtis.

"Cornubia's" assertion that I said La France was a weak grower is equally erroneous. I said it was a "good grower, very hardy, with fine foliage," but not a free bloomer here. I recommended it be placed under glass, as more likely to bloom freely.

Edward Morren and Felix Genero will stand in the catalogue for many years. Granger and Damaizin need not be disheartened. All comers here admire specially these two Roses; and Baron Chaurand is rightly called by Mr. W. Paul "one of the best dark Roses." Louis Van Houtte does not do well on Manetti, but admirably on Mr. Prince's seedling Briars.

I believe I stated that the line of Marie Baumann this year in the fine land of the Dorset nurseries was miserable, where Madame Vidot was stout and Madame Rivers from 3 to 5 feet high.—W. F. Radclyffe.

FRUIT PROSPECTS in the NORTH of SCOTLAND.

After one of the most severe winters which has been experienced during the last thirty years, spring and fine weather have at length set in. The gardener's time is now a busy time, but he has the satisfaction to feel that his prospects of fruit are favourable.

Peaches, Nectarines, and Apricots are fully in bloom, and give promise, with fine weather, of an abundant harvest of fruit. Pears, Plums, and Cherries are rapidly bursting their buds, and will shortly be richly laden with blossom. Apple blossom promises to be unusually abundant, and with a favourable season the crop of 1875 must be very large. Small fruits, so far as can be seen, are also showing exceedingly well.

Vegetables are generally late, the young Cabbages being smaller than when planted-out in October. They have been covered with snow almost continually from the end of November to the end of February. The snow has afforded great protection to vegetables; Broccolis, Brussels Sprouts, and the different sorts of Kales are now abundant and good. Altogether, if the winter has been trying the spring is encouraging, and we are hopeful of a fairly prosperous season in the northern district.—David Long, *Banffshire*.

VINES UNDER LOW TEMPERATURE SHANKING.

Mr. Taylor in one of his practical articles has incidentally advocated a low temperature for setting Grapes, and as constituting an important element in preventing shanking. On page 229 that cultivator states his practice to be a "minimum temperature of 55° for all Vines, including Muscats, till the flowers are set, and 5° lower will do them no harm at any time." Now that is 50°, and it is certain that many Grape-growers would consider that fatal to the free setting and prosperity of their Grapes.

It is well known that some of the best Grapes are produced under a much higher mean temperature than that recommended by Mr. Taylor, but that does not prove him wrong even if the higher temperature so given proves itself right. With a comparatively high night temperature under which Grapes are successfully produced, other contributing conditions will be found associated, such as inside borders carefully tended and managed, or outside borders judiciously warmed. High temperature in such cases loses relative value, and indeed may not be high at all in the sense intended by Mr. Taylor.

On the general question, it is quite certain that Mr. Taylor in advocating a low temperature and steady movement in the first stages of a Vine's growth has struck an important chord, in harmony with sound philosophy and proved to be successful. The tone of his article must commend itself to the common sense of impartial cultivators, as striking directly at the great contributing cause of Grape-shanking. There may be other and local causes which invite this fell scourge, but a too quick swelling of the buds and a pulling out of the young shoots—for that is an expressive term to use—is the one great governing cause which not only brings shanked Grapes but brings also, with equal certainty, red spider. By that practice flimsy foliage and a yellow-green wood destitute of tissue is produced, and hence a pasture ground for the pest is provided.

In dealing with Vines generally, whether in pots or not, and under whatever circumstances, and with whatever variety, safety from shanking and certainty of clean foliage and perfect fruit undoubtedly lies in a low temperature and steady movement in the first phases of Vine life. When once the roots are at work in a free and natural manner, and affording a full supply of food, then push on as you like in reason, but until then a golden motto is "Steady, boys, steady."

It is the practice of the best cultivators who have unbounded

heating means at hand to let the first steps be steady steps, knowing they will gain in the end both in the matter of time and quality. Not long ago in looking through the Burghley vineries the Vines were observed to be breaking sturdily and strongly under a very cool temperature. "Gently at first is my plan," said the veteran Mr. Gilbert, and the system has proved him right in past years, and will as certainly prove so again in the season now ensuing.

For ten years, in the case of Black Hamburgh Grapes, the practice of the writer has been studiously to keep the night temperature down to 50° until the bunches were thinned. Many times the thermometer has been 4° and 5° lower than that, even when the bunches have been in bloom, and never once has injury resulted. Never once has red spider been seen, and not one berry in a thousand has shanked. Canon Hall Muscat has been set admirably at 55°, and infinitely better than under a higher temperature. Of course atmospheric moisture and systematic ventilation have been carefully managed and regulated according to circumstances. This is only a lesson which outdoor Vines teach, and their teaching was followed. They set freely under the same low temperature, they never shank, and are seldom infested by red spider—never if kept well supplied with water.

Sometimes the effects of thrips are mistaken for shanking. Even one or two of the insects will ruin a bunch of Grapes, and their presence is frequently not observed. They will nibble round the bunch-stem just at its junction with the shoot, and check the flow of sap which should go to perfect the fruit. Two years ago I observed great damage from this source. The foliage was clean and healthy, not an insect to be seen on the leaves, but the bunch-stalks were attacked. Sometimes one and occasionally two and three of the thrips were found paring round the stalk, and would have certainly ruined the crop if they had been permitted to enjoy another week's grazing. They will not start there in the case of Vines with flimsy foliage, but only when the leaves are stout and leathery do they choose the bunch-stalk as the most vulnerable point of attack, and commit damage before they are seen.

To what has been said on low temperature a word of caution may be needful. Unpractised cultivators—learners who are feeling their way in Grape-growing—may imagine they have been working too high, applying too much heat. Go on gently as you are for this season. Make no sudden 10° drops as a remedy; that were too ruthless, but if Grapes do not satisfy this year try a lower mean the next and expect improvement. In the meantime give air early, yet carefully, regulate moisture with temperature, and above all keep a sharp look-out for the very first inroads of insect pest, as, if nothing else will cause the Grapes to shank, thrips will certainly do so, and often before they are observed.—A Surrey Gardener.

BEDDING CALCEOLARIAS.

The bedding Calceolaria has of late years proved itself to be one of the hardiest of bedding-out plants, and in many places now occupies a third part of the space allotted for summer bedding. Being anxious to keep as many of these as possible, I procured a new frame, placed it on a border facing the west, into which I put 4 inches of rotten dung; on this I placed 6 inches of fibrous soil and white sand mixed. On the 25th of October I inserted nine hundred Calceolaria cuttings. Notwithstanding the severe winter—there having been more than once 32° of frost—and they having no covering but the glass and an occasional inch of snow, the plants are growing vigorously, and have been topped repeatedly.

After the middle of the present month I shall put them into trenches to make room for more tender plants. This method I carried out last spring with some success by digging-out trenches 2½ feet wide and 15 inches deep, into which I dig rotten dung and a little river sand. When lifted for transplanting in the flower garden the very smallest balls of soil would have filled a 4-inch pot and they received no check by planting. With some more dung put into the trenches they become very suitable for growing Celery.—William Laurie.

Borage as a Decorative Plant.—I enclose the photograph of a plant of the above (for which I am indebted to Mr. Batters, gardener, Chilworth Manor) to show that it answers well for decorating purposes. Its deep blue flowers and dark green and handsome foliage show out well as seen in the photograph. It is suitable for grouping with other plants or as a single specimen in the conservatory. It was taken up from the open ground with a few more small seedlings equally as good in the autumn, potted and placed in a warm house till it flowered.—F. H. Froud.

[The photograph is exceedingly good, and we are sure the plant thus well grown is effective when grouped harmoniously with others.—Eds.]

VIOLETS: VARIETIES AND THEIR CULTURE.

To-day I send you a box of Violet blooms which I have just gathered. They are all grown out of doors and unprotected, which accounts for some of the double blooms being imperfect. I think there are fourteen varieties—three of single White, six of single Purple, one of double Purple, one of double Red, one of double White, one of double White and Lilac, and one of Lilac. The Russian, you will see, are now past their perfection. As a variety it has no equal, I think, for midwinter flowering. Then the kind known as the London blooms next. It has a more compact flower of deeper colour than any other; its leaves grow high, are earlier, and have a far paler green, are produced with the flowers, and thus protect the latter from frost. The Czar are very fine and beautiful in March, not before or after, being naturally coarse I think. It has but a limited time of beauty, with leaves darker than others. Odorata pendula, of New York I believe it to be, as a spring bloomer has, in my opinion, no superior, with blossoms as large and larger than The Czar without its coarseness, and which also expand more fully on a very long slender stalk, and with rather pale foliage. The two small blue flowers I send are an offshoot of a small variety, which may be the common wild Violet; it has very dark green leaves. The double blue, and double white, with lilac back, bloom profusely out of doors, and are most beautiful all April; but the Neapolitan double red and double white I find bloom but poorly unless protected. The single white, I imagine, is but a variety of the wild Violet.

There are several other kinds I am aware, which, added to those I have the pleasure of sending you, surely form a family of easily-grown hardy plants, that would be more cultivated were they more generally known. I may truthfully say I have gathered, literally, bushels of bloom this last winter and spring, some of which have found their way to the London Flower Mission for distribution in hospitals, and no flower can be more suitable for such a purpose. The Violet, for its delicious scent, early and continuous blooming, and easy culture, is universally a favourite amongst flowers, and must become more so when its many beautiful varieties are recognised. Is not the reason of its partly hidden merit due to the fact that it is not a paying subject with the florist? for the reason that when once supplied with a plant or two no more are required, because it is so hardy and self-increasing that a stock is thus procured without the hazard which attends the propagating of many plants.

My mode of culture is simple enough. After the blooming season I take rooted offshoots from the parent plant, which I place rather close in rows, each row being 2 feet apart, and in autumn I bank the rows up (as it were) with a small quantity of rotten manure, and then leave them alone.

There are plenty of other hardy flowers on which I will speak at length.—Henry W. Cooper, F.R.H.S., *Surrey*.

[All the varieties sent to us are distinct and well grown. Florists, we think, do not cultivate Violets largely because the demand for them is very limited. They are not gay flowers for the border.—Eds.]

THE GREAT HORTICULTURAL SHOW AT ANTWERP.

In the most excellent and able report in your last number on our Horticultural Show there is one omission on which, for the honour of our city and that of our Royal Horticultural Society, I beg to call attention. It concerns the beautiful and rare specimens you noticed as contributed by your countryman, Mr. B. S. Williams. It is quite true they were not entered for competition, and could not in consequence come under the public notice of the Jury; but the Board of Directors of the Royal Horticultural Society immediately met and voted the award of a medal of honour to the exhibitor as an unanimous expression of admiration and gratitude.

It is to the fact that this decision about such an exceptional distinction only being placed on Mr. Williams's collection of

plants just after your reporter had completed his notes, that the omission is attributable.—J. Everaerts, *a Director of the Royal Horticultural and Agricultural Society in Antwerp.*

ANEMONES AND THEIR CULTURE.

When I look at the lovely beds of semi-double Anemones now in blossom in my garden, the intensest brilliance side by side with the softest harmony of colour, I think how much those lovers of spring flowers miss who do not treat these beautiful blossoms with somewhat more care than is usual. Besides their beauty of form and exceeding richness and variety of tint, which I scarcely dare to dwell on lest it should seem exaggerated, the Anemones possess the great charm of producing blossoms all through the dark days of winter, to which their brightness forms such a cheering contrast. The bed I now speak of has supplied me with continuous bouquets from last October up to the present day, the size of the flowers of course increasing with the advance of spring, which is the meridian season of their beauty; but if there is a mid-winter open-air bouquet more lovely than a flat vase filled with scarlet Anemones along with blossoms of the large Christmas Rose white as a snowdrift, I can only say I have never seen it.

Observing so many spring flowers praised in your Journal I have often wished to say a word for the Anemones, but the old saying, "No Irish need apply," has hitherto deterred me. However, last week having shown my flowers to several florists, their hearty exclamation that they had never before seen such beautiful Anemones, tempts me now to give my mode of treating them, in the hope that others may have equal enjoyment in their blossoming.

Having saved the seed the preceding May, in March or in April I select a piece of good ground in a warm situation. I have it well dug and made fine, and then over the surface I have spread a layer of fresh cow droppings collected from the pasture; this is dug in from 5 to 6 inches deep, and then some well-rotted leaf mould is mixed with the upper 2 inches of the bed; it is raked fine, and all is ready for sowing. I then take the seed and mix it with my fingers in some sand that has a little moisture—just enough to make it adhere to the seeds, and thus separate them. I next sprinkle the seed thus prepared over the bed, not too thickly; and having ready some fine mould, I with the hand shake enough over the bed to cover the seeds, but not bury them.

Whenever weeds appear they should be pulled up while they are yet so small that their removal will not disturb the Anemone seedlings, which are tardy in appearing and slow in their first growth; but by August they should be sending up flower-stems, a few only at first, but increasing every week, until by the end of October the bed is well filled with blossoms, to continue so all winter until spring adds fresh vigour to its splendour.

I enclose some blossoms pulled to-day, so that they may speak for themselves.—L. L.

[We never saw more beautiful specimens of the semi-double Anemone.—Eds.]

PEARS—EASTER BEURRÉ.

Thanks to the contributors of our Journal for their various hints on different kinds of Pears. If thought worth recording, I send the experience of a gentleman on the ripening of Easter Beurré Pears. He planted a tree fifteen years since, and when it began to bear he carefully packed the fruit in dry sand and placed in a warm cupboard, but by this plan they were never worth eating except by cooking them. His new plan he thus describes: "Having had no success in ripening Easter Beurré Pears, after gathering them, last autumn I laid them up on shelves in a shed with Apples, covering them with cloths, where they have been all the winter, and for the last few weeks have ripened perfectly. They are of large and even size, and very valuable. The tree is against a wall."—J. W.

Sales of Plants.—Mr. J. C. Stevens sold by auction on the 8th inst. 447 lots of Orchids, which realised nearly £1500. The specimens which sold for the highest prices were Dendrobium Falconeri, £5; D. crassinode, £5 5*s.*; and "a grand mass" of D. Wardianum—seventy bulbs, besides young growths, one hundred guineas.

On the 9th Mr. Stevens sold 318 lots of the late Mr. Philpot's stove and greenhouse plants for £470. Anthurium Scherzerianum was knocked down for £7; Azaleas for from £5 to £6 10*s.*; Erica Cavendishii for £10; and Hedaroma tulipifera for £21.

THE BOUQUET AND HOW IT IS MADE.

As I have had some experience in bouquet-making I should like to add a hint to "J. H.'s" article. I must differ from him in one or two points, but will admit that the flowers named are good for the purpose. I find it impossible to make a good-shaped bouquet with the finest copper wire, as it is not stiff enough to hold the flowers in their place.

Now the way that I proceed to make a bouquet is thus:—I procure some iron wire stiff enough to bear the weight of a Camellia in any position. I cut this in lengths of about 7 inches, and next cut my flowers, and wire every one, whether it has a long stalk or a short one. I next have a stick about the size of a cedar pencil, and 7 inches long, and bind the centre flower to it. This forms a handle, and a good foundation to bind the others to. I use the Indian grass for binding, as the wire cuts the stalks of the flowers and Fern too much.

I use two sizes of wire, one very fine for wiring double Primulas, Hyacinths, and pips of double Geraniums, &c.; the other stout for bouquets. By so doing I can make a good bouquet with a very few flowers, which is a great saving in the winter months when flowers are scarce.—F. B.

THE ROYAL HORTICULTURAL SOCIETY—A GROWL.

Week after week have I intended to write to you, but have put the matter off in the hope that there would be no occasion for this letter, but I have hoped in vain. It is now the 10th of April, 1875, and not one penny of the prize money which was gained last year has been paid by the Royal Horticultural Society, and I write in the hope that if you take the matter up we poor exhibitors may receive our money.

I consider that the action of the Council in this matter is perfectly dishonest. In their report and statement of accounts they put down the prize money for 1874 as if it had been paid, and this report is presented at the annual meeting, and, I presume, passed. Now, what right has the Council to issue a false report? for I maintain that the balance-sheet is a false one which leads the members to suppose that the prizes have been paid when they have not.

Rose-showing is a source of great expense and discomfort to most men, but to me it is unusually so. I have to drive twenty-six miles at night to catch the London mail, and then have to travel all night and land at that most inhospitable arcade of the Royal Horticultural Society, those "*barbara regna*," in a state of starvation, and not even a cup of tea can be procured for love or money. Then, when the day is over and we exhibitors come to take away our boxes we have regularly to fight to prevent every bloom being taken by the crowd; and when you are showing in all the classes your boxes are widely apart, and it is impossible to protect more than one stand. I was asked at the last show a dozen times whether I sold my blooms, and one gentleman calmly asked me, "Do you not come from Paul's?" Mr. Eyles saw a stranger calmly take every Rose out of a stand, and on being asked whether he owned those Roses said, "No; I thought I might help myself!" A lady positively took my Roses away from my box as I was giving them away. Any exhibitor who was there will bear me out in this, and will endorse every word I have said about the arrangements.

Now, after all this trouble, discomfort, and expense we who have gained prizes are left to "whistle for them," and this from the Society which calls itself "Royal." "The Royal Horticultural Society of England" can condescend to a line of action which would not be taken by the poorest and most insignificant cottage gardeners' horticultural society. I call it simply a breach of faith, and hope you will expose it, and then, perhaps, the Council will be ashamed of themselves, as they ought to have been long ago.—A Disgusted Exhibitor.

[The preceding communication needs no comment from us. The conduct of the Council of the Royal Horticultural Society is most unworthy. If it offers prizes, even if the funds of the Society are not sufficient to pay the prizes, the Council ought to pay them out of their own pockets. They could be com-

pelled to do so in a County Court. As to the raids upon the Roses, a notice forbidding such pillage should be exhibited, and policemen be in attendance to secure that the notice is obeyed.—Eds.]

VIOLETS—A NEW VIOLET.

At the close of February last a lady sent me flowers by post from plants growiog at Parma. Their freshness was surprising, and none the less so the doubleness, size, high colour, and perfume of the blooms. It is the colour that I wish to particularly note—a decided purple, not so deep as we have it in the Double Purple King and others, but the purple shown in the spots of Queen of Violets. The flowers were followed by a dozen pots of plants, and I felt fortunate in having secured another and better form of Neapolitan, the stems being longer and stouter than in that variety; but though the opening buds on the plants promised blooms equal in colour to those received by post, they opened paler and paler each succeeding bloom, until now they are very little deeper in colour than the sky-blue Neapolitan, which we have in frames and outdoors. Other plants came to hand from Paris, taken from the open ground, had the pale blue of the Neapolitan.

Can any of your correspondents inform me if the size and deep colour of bloom of the Parma Violets and their length of stem is due to climate and soil, or to some peculiarity of treatment? We all know of the change of colour effected in the bloom of Hydrangeas; by the application of iron filings and a solution of alum the rose of that flower is changed to blue. The same thing occurs when the plants are grown in peat soil, or an admixture of peat containing oxide of iron.

Plants and blooms have also reached me by post of a new Violet—viz., Prince Consort, raised by Mr. Lee, Cliveden, who is also the raiser of Victoria Regina. I had an opportunity, therefore, of forming an opinion both of bloom and plant. The plant, as it appears to me, is not so strong in foliage and habit as Victoria Regina. The leaves are more like Czar, and do not droop as in Victoria Regina, but are equally fine and glossy. The flowers are a little larger than those of Victoria Regina, are a little paler in colour—a pleasing bluish purple—with petals more rounded, the flower altogether having the form of a well-formed Pansy, whilst it has stout long flower-stems, and the perfume is delightful. It is a fitting companion for Victoria Regina, and as great an advance upon that variety as that is upon Czar.

Victoria Regina both in frames and outdoors is much better than Czar, the flowers are larger, the petals have greater breadth and substance, are more even and circular in outline, and are of deeper colour. To the raiser of this great improvement in Violets I am indebted for a number of blooms of seedlings raised from Prince Consort, the size of all being greater than anything we have in sweet single varieties, and of as many shades of blue and purple. Many of them have the outline, the smoothness, the rays and eyes, the substance, and not far beneath the size of Pansies, all having in the highest degree the fragrance of the Violet. One I particularly noted as not dissimilar from Viola incana, being exactly like it in colour; others must partake of the nature of V. cucullatum.

These are splendid specimens of Violets, and when once seen are not soon forgotten, their fine form, substance, colour, and fragrance alike impressing one with their superiority over the older varieties.—G. Abbey.

EUPHORBIACEÆ.

More than 2500 species are included in this botanical family, and nearly each of them has in its sap some portion of one of the most virulent of poisons—a resin called by chemists Euphorbium. It is in the diminutive weed common in our gardens—the Spurge, or Wart-wort, Euphorbia helioscopia, as well as in the Euphorbia tree, found at Dufar and elsewhere in northern Africa, depicted in the accompanying woodcut.

A recent traveller informs us that, being at Dufar in the neighbourhood of the gigantic Euphorbium, he requested one of the negroes to go with him to the tree. The fellow hesitated, excused himself on various pretences, but at last consented to go. It was evident that he was in extreme fear, and that his terror increased the nearer he approached the tree; he lifted his large eyes several times to its branches, and apparently entertained the notion that he was treading on forbidden ground. He stood by without uttering a syllable, but in a high state of nervous excitement, while the traveller made his sketch; but when, on its completion, the artist suggested breaking off a branch as a memento of the visit, the terror of the negro became extreme. His gesticulations were irresistibly comic, his language utterly incomprehensible, but it was clear enough that he felt sure some dire penalty would follow the commission of such sacrilege. At last he said in a sort of moongrel Arabic, "Touch it, and you'll die—it will kill you—it always kills." But the branch was broken off, and the sap, a milky-looking fluid, burst out far more copiously than the traveller had anticipated, and penetrated his outer clothing in an instant. He soon understood the cause of the negro's terror. The sap was a deadly poison, and he was assured that if he had any wound or scratch upon his body the result would be fatal. Fortunately for him he had not.

The Euphorbium, of which we give an illustration, grows on the mountain of Kaçane. It measures about 80 feet in circumference; its height is about 30 feet. The trunk is a piece of hard firm timber; the branches are cyliudrical in form, and interlaced.

There are other arborescent Euphorbiæ strikingly peculiar. Euphorbia balsamifera, the milk of which is so innocuous and sweet that it is thickened to a jelly and eaten by the inhabitants, is a very remarkable tree. The trunk, though very crooked, at first rises without branches, but afterwards divides into a great number, which again divide into innumerable smaller branches. Leaves are nowhere to be seen but at the extremity of the branches round which they are placed. They are short, lanceolate and narrow, grey, and furnished with a little thorn at the point. The Cordon (Euphorbia canariensis, the juice of which is as acrid as that of the other Euphorbiæ) is a still more wonderful production of nature. Its dark green branches, completely leafless, rise all at once from a common root, bend in a semicircle down to the ground, and then rise again perpendicularly at various distances from the first root, so that the tree resembles an enormous lustre with a number of branches bearing lights. Each branch is as much as half a foot in circumference, and is a prism of four, or more generally of five sides. Their edges along the whole length are set with pairs of short prickles. At the extremity of these thick, angular, fleshy branches break forth the scarlet flowers, which at a distance are like burning coals. Higher up the older branches divide, and form separate smaller lustres on the larger one.

According to Endlicher, Euphorbia officinarum is the plant that King Juba discovered in Barbary, and named after his physician, who was brother to Musa. It is a native of Africa, Arabia, and India, and is one of those Cactus-looking species, without leaves, with erect, thick, fleshy stem and branches, having the appearance of candelabra; each branch is terminated by a red flower, and is covered with knobs, from which issues a sharp spine. It is called Furbiurne by the Arabs, and Dergmuse by the inhabitants of Atlas.

The above-named species are thus described by Meyen, Dr. Hogg, and in Messrs. Cassell's "Magazine," who have obliged us with the accompanying woodcut. We now descend to a few of the species cultivated in our gardens. The Spurgeworts are generally characterised by quaint form or habit, there being very few which can be regarded as beautiful flowering plants. Yet we find a trio of species worthy of general cultivation, and to these we draw timely attention.

E. splendens is a Madagascar plant, which adds to singularity of form flowers which are highly attractive. These are produced in clusters of two to six, on short footstalks. They are of a pleasing soft scarlet colour, and for button-hole bouquets are extremely suitable. The plant is of a prickly erect shrub-like habit, and may be grown as a wall plant in the stove, or be trained as a specimen to stakes or a wire trellis. It is of easy culture, and blooms profusely over a long period of the year. It is propagated by cuttings put in at the present time. Short stubby side shoots with a little old wood at the base of each are the best. They should be laid for a day to dry—as the cuts bleed profusely—before they are put in. They require sandy soil and a brisk heat. When struck they require to be grown in the full sun of a well-heated structure. The plants must be watered with care until the pots are filled with roots, and must be kept comparatively dry during the winter season. When once established the plants will continue to bloom for a number of years, and are useful as affording cut blooms of stout texture, and of a colour hardly to be found on any other plant.

E. punicea is a somewhat rare yet a beautiful species of this family. It is a native of Jamaica, and although it has been known to our gardens for more than a century, it is but seldom

seen, probably on account of its difficulty of propagation. The plant is of shrubby habit, and its dazzling crimson-scarlet bracts render it extremely attractive. The plants should be dry almost to flagging before the cuttings are taken off, when they will strike in brisk heat in gritty soil. The plants should be grown in sandy loam containing a liberal admixture of nodules of broken bricks and limestone. It will thrive in a greenhouse during the summer months, but at other times requires a stove temperature. It is a bright and attractive plant, worthy of general cultivation.

E. jacquiniæflora. We have no need to sound the praises of this deservedly-popular winter-blooming plant; its merits are well known, and its charms are universally appreciated. It should be grown in every garden which affords conveniences

Fig. 67.—Euphorbia tree at dufar.

for its culture, so elegant and attractive are its highly-coloured sprays, for purposes of cut blooms especially. The plant is of straggling habit, but is tractable and amenable to different forms of culture. We have had it planted out and covering the back wall of a vinery, and have gathered therefrom immense quantities of sprays. We have had it in glowing pyramids trained to wire trellises, and we have grown it by dozens in small pots for filling jardinettes and other indoor decorative purposes. Short-jointed cuttings strike freely in sand under bell-glasses at this season of the year, and every cutting will flower in the autumn. In order to have compact plants we have struck the cuttings in May in thumb pots and transferred several of these plants into a 6-inch pot, and in the winter have had masses of scarlet not more than 9 inches in height. The plants should be grown on shelves quite close to the glass, and should have copious supplies of water throughout the summer. Loam with lumpy peat and charcoal is a suitable compost. The drainage must be perfect; for while this plant requires plenty of water, any approach to a stagnant soil is fatal. It must, moreover, not be overpotted. For covering the back wall of a

stove or temperate house few plants are better suited than this, as wherever it can have light and heat it will grow and bloom profusely. It is quite safe in the winter months if the temperature is not below 45°, and at that season very little water is required to keep the plant in health.

NOLANAS.

Our illustration (fig. 68) is not a good typical representation of a class of hardy annuals which contribute an air of gracefulness and a feeling of repose amidst the more brilliant masses of colour in the garden where they have a place. They are convolvulus or bell-shaped flowers in which blue in varied tints predominates, and their low trailing habit of growth renders them suitable for many purposes of decoration. While they cannot be regarded as occupying an important rank in the floral category, or be classed as prominent or indispensable in creating any distinct effect, yet, like annuals generally, they have a charm all their own, and are more beautiful than many plants which are more extensively cultivated.

They are natives of Chili and Peru, the oldest variety, N. prostrata, having been introduced in 1761, and the newest, N. lanceolata, about 1862. N. atriplicifolia is the variety best known; it is in colour blue, white, and yellow, and is a pretty graceful annual. N. cœlestis is a pure light blue of a pleasing tint. N. paradoxa violacea is a deep lavender violet, with a yellow centre, and is very gay. The best, however, of them all is N. lanceolata. It was introduced by Messrs. Veitch & Sons. The "Botanical Magazine" for 1862 contains a beautiful coloured plate of this plant, and describes it as a charming addition to our hardy annuals. It was discovered by Mr. Cumming at Coquimbo. In colour it is a rich mazarine blue with a white throat, and in shape is similar to a Petunia. The colour of this flower is almost unequalled in its way, and we may add as a point in its favour that it is a fashionable colour.

Fig. 68.—Nolana lanceolata.

It is very rarely that this pleasing class of flowers are honoured with a notice except in seedsmen's catalogues, yet we make no apology for drawing attention to them here, and also in giving an example of their features, for the beautiful colour alone of the variety last named merits attention, and will afford to the many admirers of blue flowers a tint which they cannot easily find in any other plant, texture, or pigment.

The notice is further opportune as being the proper time to sow the seed. It simply requires to be sown where required to bloom, or in pots and transplanted. This plan is advisable with any cherished annual where slugs are prevalent. The Nolanas grow less than a foot high: hence are suitable for growing near the margins of borders. By their trailing habit they are suited also as drooping plants, and are further well adapted for window-box culture. To those who enjoy the raising of simple flowers from seed, and who have pleasure in seeing a reward of their own hands within a few weeks of sowing the seeds, will instinctively turn to hardy annuals, and amongst these we would advise them to no longer neglect, if they seek a charming blue, Nolana lanceolata. For children's gardens especially—and we would offer fare for all tastes and requirements—these simple, attractive, and easily-cultivated flowers should be adopted, as, besides affording pleasure, they are instructive in imparting a lesson, and in cultivating a pure and refined taste. Thus even annuals may have a use.

NOTES AND GLEANINGS.

A rumour having obtained credence that the Council of the Royal Horticultural Society do not intend paying the prizes of 1874, we are requested by the Secretary to say that such a rumour is unfounded in fact, and that the prizes of 1874 will be paid as soon as the funds of the Society will admit of it.

—— New editions of Gordon's "Pinetum" and Paxton's "Cottager's Calendar of Garden Operations," have just been published.

—— At the International Exhibition to be held at Philadelphia in 1876, our Government have decided that the interests of the British section shall be entrusted to the Lords of the Committee of Council on Education. Anyone wishing to exhibit should apply to R. Cunliffe Owen, 5, Craig's Court, Charing Cross.

HARDY VINEYARD AT CARDIFF CASTLE.

There are instances on record of the cellars of some of our British nobles being pretty well stocked with wine the pro-

duce of Grapes grown in the open air on favourable spots on their own domains—such, for instance, as at Arundel Castle. The Most Noble the Marquis of Bute is at present engaged in preparing a piece of ground on his Cardiff estates for the formation of a hardy vineyard on a somewhat extensive scale. The ground selected is about seven miles from Cardiff, at a place called Castle Coch, an old ruin which his lordship is having partly restored. This castle is situated on a tract of limestone some five hundred acres in extent. It is well wooded to the north, east, and west, but lies quite open to the south, overlooking the Bristol Channel. The field selected here for the vineyard is about five acres in extent, having a good fall to the south. It is of a light loamy soil, 2 feet deep resting on the limestone rock, and requiring no artificial drainage. The only preparation necessary before planting is trenching, and slightly manuring with stable dung. The Marquis, in his earnestness to put the practicability of open-air culture of Grapes in favoured spots in this country to fair proof, sent his intelligent gardener, Mr. Pettigrew, on a tour of inspection among the most noted French vineyards last autumn, preparatory to his lordship's desire being put into practice. Two thousand Vines will be planted this year, and the same quantity next year, and so on until the vineyard is stocked. They will be planted 3 feet apart each way; and it is proposed not to allow them to grow to a greater height than 3 feet. The varieties to be planted are Melier Blanc and Gromier Noir, in equal proportions, these being, from Mr. Pettigrew's observations on the Continent, the two most likely to succeed—they being very hardy and prolific. To further test the matter, 150 Chasselas Fontainebleau are to be planted on the castle walls. We earnestly hope the Marquis's experiment may turn out very successful. It may be added, the French system of culture will be adopted generally.—*(The Gardener.)*

NOTES ON VILLA AND SUBURBAN GARDENING.

Window Gardening.—Of the different phases of town gardening there is probably not one which gives the observer more of an impression that flowers are grown for the very love of them than when he sees window after window from the lowest to the highest in the street tastefully decorated with growing plants. The outside furnishing of them involves a little trouble, though the season for that is of short duration, yet the success which attends those who make an attempt at this form of gardening are paid for their trouble by a few beautiful flowers, as well as a cheerful aspect given to the whole of the house internally and externally.

Though the season is advancing it is yet too early to trust tender plants outside; however, the time is come when preparations may be made with the view of placing them outside some time next month. By that I mean the plants may be potted and grown on, and whether window boxes or any other vessels are used for the purpose the plants should be placed in them now, and grown for the present in some sheltered place, or in a frame, and perhaps for a time in the greenhouse, and have them established before placing them in their positions. They will then give an effect at once, which is an advantage to aim at, particularly as the season for such plants is short.

Plants for indoor window decoration may be trusted near the glass with confidence night and day, as no frost may now be expected severe enough to reach them, particularly if the window has a good sunny aspect. There is one very important thing to take note of which operates against the well-doing of outside window plants, that is the summer's sun playing with full force upon the pots or boxes, burning as it were the young fleshy roots so necessary to the health of the plants, and causing such a rapid evaporation from the soil as to incur in ordinary cases too much watering for the health of the plants to be good. To obviate this injury in some measure the boxes should be in two—that is, the ornamental or outer box should be as a casing to the other, or, if pots are used, one should be set in another. This gives all the protection required, excepting that the surface of the box or pot should be mulched or covered with moss or cocoa-nut fibre to prevent evaporation.

There are many ways of decorating a window with plants, and there is a nice variety of plants fit for the purpose; but taste in arranging this must be to some extent guided by the shape and size of the window to be decorated. It is quite natural to suppose that the plants inside if arranged along the front, with the tall plants at the back, will present a broad face to the outside; but if indoor and outdoor decoration is attempted in the same window this plan would do away with the effect of the outside; but if the plants indoors were reduced to a low number, say six on each side, the most of which would be best not more than from 6 to 18 inches high, leaving the centre of the window clear to view the plants outside, then if these were arranged as to height in conjunction with those inside, and on the side also, gradually bring the dwarfer towards the centre; this would give a view of two banks of plants in flower on each side, which would look remarkably well.

Then, again, there might be a slight wire narrow trellis to run over the window against the wall, which would look well covered with the common Canary Creeper, or any other suitable plant; or a trellis might be fixed of a triangular shape on each side of the window, say 2 feet in width at bottom, terminating to one wire at the height of the window, leaving the top without any. This plan would look well if covered with Ivy, and would afford some shelter from the winds that do plants harm by cutting by the windows of narrow streets.

The mixed style of planting or arranging the plants seems to be about the best, because there is not room for much distinction of colours, and, besides, all plants do not thrive well at one time, and the mixed plan would ensure always some plants to be in flower, while the inside of the window might be filled with such plants as Pelargoniums, Calceolarias, Fuchsias, Hydrangeas, Heliotropes, and Balsams, and others of what are called greenhouse plants. The outside would be creditable in appearance if Stocks, Mignonette, Scarlet and Variegated Geraniums, Lobelias, Calceolarias, and Verbenas were used. They are pretty sure flowerers, and although there are many other plants which would claim some notice as suitable, they would require to be supplemented by others frequently, as they would not stand that treatment long without exhibiting signs of distress.—Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

All early spring-sown crops are making healthy progress. Although February and March have been cold months very little rain has fallen, and when cold weather prevails in these months all out-of-doors crops do best when the surface of the ground is dry, as there is always plenty of moisture in the ground from the autumn and winter rains. At Loxford the rainfall for February was a trifle over an inch, and in March but half that quantity fell.

The early Peas have grown up to the wire protectors; it has been necessary to remove these to the second sowing just coming through the ground. The rows were earthed-up at once and the sticks put to them. When they are so far advanced the sparrows seldom attack them. It is a good plan to put in some short sticks about a foot high first, and when the Peas have taken hold to use the taller sticks.

Cauliflower plants that have been under handlights through the winter are well advanced. The lights have been removed, and the ground forked over amongst the plants. The sowing that was made early in the season on a hotbed is not quite ready to plant out. To keep up a succession another sowing ought to have been made out of doors about the last week in March; but it is not possible to produce good Cauliflowers in July and August in our light soil, and after many failures the attempt has been given up.

The Lettuce seed sown under ground vineries has produced abundance of stocky plants; and a shower of rain, though it only moistened the surface of the ground, furnished an opportunity to plant out a quantity of them. Hicks's Hardy White Cos is the favourite: this variety, though evidently only a form of Paris White Cos, is certainly the best of the many selections of that excellent sort; its superiority of growth is already apparent. Ran the hoe through all ground occupied by growing crops, using the Dutch hoe for fruit borders, and the ordinary draw hoe for spring Cabbage and similar crops.

Sow Salsafy, Scorzonera, and Beet. The Beet need not be sown on rich ground, as medium-sized roots are preferable to large overgrown specimens. The others cannot be grown too strongly, but avoid sowing on ground that has been recently trenched if it has been manured with rank dung. Ground that had been trenched before Christmas, and the manure placed about a foot under the surface, is the most suitable for this crop. A sowing of Broccoli should now be made, comprising the earliest sorts. The bed of Globe Artichokes should now be forked over, removing all superabundant suckers from the plants as the work progresses; these will be useful to make a fresh bed, and if required for this purpose should be planted at once. The earliest-sown Celery must be pricked out on a warm border, allowing 3 inches between the plants. A small number of plants will be sufficient for the earliest crop, as so many of them run to seed even with the best management. Sow now for the latest crop in the open ground. Lettuce, Radish, and all small salading ought to be sown frequently according to the demand for them.

Now is a good time to sow herbs of sorts, such as Fennel, Marjoram, Basil, Borage, Thyme, Chervil, Savory, &c.; also to plant-out Sage, Thyme, Tansy, Mint, and Tarragon. The last is much used, and succeeds best in a dry border. With the next

sowing of Peas sow Round-leaved Spinach between the rows. The kitchen garden should now be neat and trim, the edgings of the quarters to be made up with a spade and cut off to the line, raking the alleys afterwards. Many persons leave trimming the Box edgings until May; but if time can be spared now it ought to be done, and all the walks to be cleaned and rolled.

FRUIT AND FORCING HOUSES.

Strawberries.—A succession of these ought now to be kept up until the fruit is gathered in the open ground. Any plants that were placed in the late vineries to start with the Vines ought to be removed into another house, as the Vines will soon shade the plants, and the Strawberry will do little good forced in pots if not placed near the glass and freely exposed to the sun. We have now a batch of Keens' Seedling (and the fruit is just ripening), which were started in a house the temperature of which was 50° at night; they were removed to the Pine house with a minimum of 60° or 65° after the flower trusses were thrown up. The flowers must be thinned-out as soon as possible. About nine fruit on an average is a sufficient number to allow on 6-inch pots. If the pots are on a shelf quite close to the glass, and facing south, the best way is to allow the fruit to hang over the pots without any support. If the pots are unfavourably placed as regards light and sun, then the fruit ought to be fully exposed above the foliage by tying it up to small sprays cut from any brush or faggot wood. It may be as well to say a word on watering. When the plants are in a high artificial temperature then the water that is applied to roots or leaves should be of the same temperature as the house, and no plants should suffer for want of water. Manure water is indispensable to the production of superior fruit, and the best is made from either cow or stable manure. We generally use cow dung for mixing with the water, because the compost at potting time is formed with stable manure; guano is sometimes used, but it is a bad stimulant for Strawberries in pots. We have also tried placing the pots in saucers to hold water; this is a considerable saving in labour, but the fruit will not be so good.

ORCHARD HOUSE.

The trees of Peach and Nectarines are now in flower, and as the weather has been so favourable a good set is almost certain. It is well to go over all the trees daily when they are in flower, some time in the forenoon, and just shake the trees gently to disperse the pollen. Air must be freely admitted at the time of flowering; a close damp atmosphere is fatal to a good set. Pears are also very nearly in flower. The fruit does not set so well under glass as that of the Peach. Dewing the blossoms over with clear water from a syringe on the morning of a fine day is a good way to scatter the pollen and to promote fertilisation.

Cherries under glass require a dry bracing atmosphere when the trees are in blossom, and if the trees are in pots they must be well attended to with water; the blossoms do not set well unless the trees are in favourable conditions. Peaches, Nectarines, and Plums succeed well in the same house. Cherries and Pears ought to be together, as a drier atmosphere is required all through the fruiting season.

CUCUMBER AND MELON HOUSES.

With the longer days and milder weather it is easy to maintain a minimum temperature of 70°, allowing it to rise to 80° or 85° from sun heat. In our house the pipes seldom require to be very much heated to keep up the necessary temperature, and yet half the quantity of evaporating trough is enough. Even Cucumber plants may be overdone with moisture. The plants are now syringed daily with clear rain water, applying it to the under sides of the leaves. Frequent syringing and judicious air-giving is the only way to keep the plants clean and healthy.

Melons are grown with a night temperature of 65°; the leading growths have been stopped, the lateral growths which furnish the female blossoms are trained to the trellis as they grow out, and when four or six female blossoms are in flower at once they are impregnated. In fine weather the plants are syringed daily; it is the only way to prevent red spider injuring the plants.

PLANT STOVE.

It is now good time to propagate by cuttings any of the soft-wooded or other rapid-growing plants. Thyrsacanthus rutilans should be propagated annually. The cuttings of the young growths root freely in loam and leaf mould in a high temperature; the numerous drooping panicles of scarlet flowers are very ornamental in early spring. The plants must be potted-on and grown in a high temperature all the summer and autumn. Eranthemum pulchellum is another very free growing plant, and is well worth attention for the profusion of pretty deep blue flowers it continues to produce all through the winter months.

Justicia is an extensive genus of plants that has fallen into undeserved neglect. Many of the species are very beautiful, and some of the best are winter-flowering. Cuttings of many hardwooded species may also be put in now; those most difficult of propagation should be potted in sand, placing a thickish layer of turfy loam or peat over the drainage. Gardenia florida strikes out roots very freely, but all hardwooded cuttings should be placed under bell-glasses or handlights.

We have been cutting-down Poinsettia pulcherrima and placing the plants in one of the late vineries to start into growth. They will grow away very freely in a high temperature, making splendid growths and handsome foliage; but it is best to place the plants in a greenhouse temperature after they are started; the growths here will be short and densely clothed with leaves.

Caladiums had also started into growth, and were removed to the Pine house. We like to have the plants near the glass, as the leaves have a tendency to be long-stalked if the plants are not freely exposed to light and air. These and the Poinsettias, as soon as they have made a little growth, will be shaken out of the pots, the balls reduced as much as possible, and the plants repotted, the large specimens in the same sized pots, and the smaller plants in a size larger.

Such Orchids as Dendrobium Bensoniæ, D. clavatum, D. McCarthiæ, D. Dalhousianum, D. densiflorum, D. Devonianum, and others of the same class, are showing their flowers, and the baskets and pots in which they are growing are freely watered with tepid water; indeed, all Orchids that have been at rest during winter may now be kept moist if they have not been overpotted. As nearly all the plants are starting into growth, a moist atmosphere and a higher temperature with shade when necessary is indispensable to healthy development.

Watch for the appearance of red spider on the young growths of Dendrobiums, some of the Palms, and other plants known to be attacked. If the plants cannot be syringed they must be hand-washed with soapy water.—J. Douglas.

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Manchester (National Auricula Show).—April 27th.
Jersey.—May 5th, Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.
Bath.—May 12th, September 1st and 2nd. Mr. B. Pearson, 13, Milsom Street, Sec.

George Poulton, Fountain Nursery, Edmonton, London.—*Catalogue of Plants and Cuttings.*

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Cucumbers (*C. Morfett*).—Write to Messrs. Webber, Central Avenue, Covent Garden Market.

Pear Grafts (*J. Badgerry*).—Our correspondent declines parting with grafts.

Rhubarbs (*J. Hood*).—The Elford is scarlet-stalked; Britannia, dark pink; Randall's, dark pink; and Myatt's Victoria, crimson. We never heard of the Peach Rhubarb.

Begonia (*G. S.*).—It is a variety, and we cannot attempt to name varieties.

Paget's Engine (*Observer*).—Your note is an advertisement.

Stove without Flue (*H. T.*).—Whether a stove is heated by petroleum gas, coke, charcoal, or any other source of heat, if there is no funnel or flue to convey the fumes or gases produced into the outside air, the plants in the house will be injured, and in many instances killed.

Deodorising Sewage (*G. Hughes*).—The earth is one of the best of deodorisers. If the liquid be distributed by a watercart towards evening we believe there would be little or no offensive smell detectable next morning. Half a hundredweight of sulphate of lime (gypsum) might be mixed with each one hundred gallons of the sewage.

Ventilating Greenhouse (*Flycatcher*).—It is proper to give air by the back lights in the first instance at every period of the year, front ventilation being secondary to the top or back ventilation, and ought only to be given when the latter is insufficient to keep the temperature from rising too high. The Cytisus is C. racemosus.

Roses for Arched Trellis (*J. P.*).—Roses admit no rival, nor could they well be associated with evergreens, as the one would outgrow the other. We presume you will have access to the Roses outside as well as beneath the trellis, for grand as may be the idea of a walk beneath an arched trellis of Roses, the main of the beauty will be on the outside; in fact, very little of the Roses will be seen from the path when the trellis is covered. We should not have an arched trellis, only arches at every 9 feet apart and 2 feet in breadth, which will give you 7 feet clear space between each, and from the walk you will see the Roses on the arches in all their beauty. Over the walk directly in the centre you may have three wires connected with the arches, which would give what we think you need—a shady walk; but we should be content with the arches, and cover the bank or both sides with dwarf plants. By this plan you would have the Roses in view from the walk. The effect when in bloom would be very fine. Of Roses suitable for the trellis we may mention *Teas:*—Belle Lyonnaise, Catherine Mermet, Gloire de Bordeaux, Gloire de Dijon, and Madame Trifle. *Noisette:* Celine Forestier, Rêve d'Or. *Bourbon:* Gloire de Rosamene, Baronne de Noirmont. *Perpetual:* Abbé Bramerel, Alfred Colomb, Auguste Neomann, Baron de Bonstettin, Baronne Louise Uxkull, Boule de Neige, Capitaine Lamure, Charles Lefebvre, Charles Turner, Climbing Victor Verdier, Edward Morren, General Miloradovitsch, Glory of Waltham, Jules Margottin, Louis Van Houtte, Madame Canrobert, Madame Laurent, Paul Neron, Perle des Blanches, President Willermoz, Princess Beatrice, Reine des Blanches, Susanna Wood, Thomas Methven, and Stanwell Perpetual (Scotch).

Bedding Plants in Stony Soil (*F. H.*).—By all means remove the stones, which if left in the soil will cause endless trouble; if so stony as to need riddling you will do well to add some good loam, or manure liberally, as in such a soil, upon gravel, the plants will hardly grow too vigorously. The process you propose following will answer for the flower beds and lawn, but we should have the depth of soil for the grass over rather than under one foot.

Melons and Cucumbers in Frames (*Amateur*).—They require air according to the weather. You will do best with a thermometer in each frame, by which you can be guided as to when to give air and when to shut-up the frames. The temperature when air is given should be 75°, and then you should only give an inch or so, or, if cold and frosty, less; and it should not be given to lower the temperature, but to prevent it from rising too high. If it lower the temperature the ventilation is too great, and if the temperature rise it is proper, and will need to be increased with the temperature, increasing the opening at 80°, and there is no need to admit more air so long as the temperature does not exceed 90°. The ventilation will need to be reduced when the temperature is falling. At 80° reduce the opening, closing the frame at that temperature, and if it rise to 85° after the removal of ventilation there is no harm, but if it rise so as to exceed that temperature the ventilation has been too early withdrawn. A little practice will soon enable you to give air without lowering the temperature, and reduce it without its rising too high for the well-doing of the plants. Mats should be placed on the lights to prevent the temperature falling too low during the night. They should be put on at about 5 P.M., and removed at between seven and eight o'clock in the morning. Blue Gown is a good Cucumber for a frame, and Little Heath Melon will answer well.

Pitcher (*Rufus*).—A letter received to-day enables us to answer your query. "A pitcher" in the West of England is the name by which is distinguished the branch of an Apple tree which has an excrescence or wen that will emit roots if the branch is cut from the tree just below the excrescence and planted. The Burr-knot, the English Codlin, and some other Apple trees commonly afford "pitchers."

Pines not Swowing (*A. B.*).—The plants not having started for fruit as you anticipated, we should keep rather dry for about six weeks, after which they will probably upon the application of moisture start into fruit. They require a moist atmosphere, and especially when they are growing and swelling the fruit, and water twice or thrice a-week, according to the weather. A peck of sheep droppings to thirty gallons of water, one peck of horse droppings to twenty gallons, or 1 oz. of guano to a gallon of water, are good liquid manures for Pines and all fruits.

Heating Range of Houses (*R. M.*).—You will require two 4-inch pipes for bottom heat to the propagating pit, and the same for top heat; the early vinery four rows along the front; the greenhouse two rows along both sides and ends except the front doorway, and the late vinery two along the front, all 4-inch-diameter pipes. As to the direction of the pipes we should take a main direct from the boiler at the back of the early vinery or in the pathway, and through to the far side of the greenhouse, having the main flow and return in a fine, and a cover of iron grating, forming part or whole of the pathway. From this main branch immediately on entering the early vinery across the end and 3 feet from the front branch to the left for the early vinery, continuing the piping to its end, and then return beneath them, or the pipes may be on the level, having a triple branch pipe next the propagating pit pipe or pipe going thereto, and a four-branch syphon at the other, one of which will be a return pipe. Continue the pipe at the end of the early vinery forward to the propagating pit, twice its length for top heat, which may be in the pathway, and twice the length of the pit for bottom heat to the propagating bed. The main flow continue through the early vinery to the greenhouse and across its back, branching immediately on entering it, taking it along its side to the doorway, and then return. At the other side of greenhouse the piping to be continued to the doorway, and then return, from the flow of this side the greenhouse branch through the wall into the late vinery, and about 3 feet from the front wall taking its entire length, returning by a syphon, and brought back to join the greenhouse return pipe. You will need valves upon all flows—*i.e.*, those of each house, immediately they leave the main in each case and two upon the greenhouse pipes, so that you may have as little waste heat as possible. The main flow and return we should have about a foot to 15 inches lower than the pipes in each house, and in all the houses have them upon the same level. You will require air pipes at the highest point of the pipes in each house, which should be immediately before the water return, and both in the vineries and propagating pit half the piping should be provided with evaporating troughs. Altogether you will have about 560 feet of 4-inch piping, and to heat this you will require a boiler presenting 10 superficial feet of surface to the direct action of the fire, or a saddle boiler about 3 feet 6 inches long.

Liming Ground for Potatoes (*Amateur*).—A dressing of lime would be highly beneficial, and that known as "land" lime is most suitable. It should be used in a quick state, and at the rate of two bushels per 100 square yards. The lime should be applied before planting—*i.e.*, spread on the surface and lightly forked-in.

Names of Plants (*Country Parson*).—The specimen was too shrivelled to enable us to identify it with certainty. It appears to be an Orobus, probably O. vernus, though it is strong for that variety. Propagation is effected by division at this season, taking off an eye or two coming from the crown, and with a portion of root attached, inserting it in sandy soil. (*A. C.*).—We cannot name plants from leaves only, nor from mere flower buds.

POULTRY, BEE, AND PIGEON CHRONICLE.

CLASSES.

We think many schedules of poultry shows need revising. We see frequently year after year the schedule of a show, especially those connected with agricultural exhibitions, copied as to its classes verbatim. No allowance is made for their being well or badly filled. "It did last year, and we suppose it will this," seems to be the idea of the committees of many such shows. Bullocks and sheep are the glory of those schedule-framers, and cocks and hens mere rubbish in their eyes. We can only say to them that the poultry tent of such meetings is not only always the most crowded, but that that is the department which brings the money in entry fees and the visitors' money at the gates. Knock off the poultry, and see whether the receipts are the same. In these days poultry shows are as thick as thieves, and exhibitors will patronise those which serve them best, and so the committees of agricultural societies must really look to their poultry schedules before it is too late. We will not here be invidious and name any particular show, but we could tell of many that go on year after year issuing their schedule a facsimile of the last one, and year after year the entries decrease, till a more than ordinarily vigorous push will have to be given to bring the poultry department once more in a flourishing way. Of course we do not expect such exhibitions to have classes for the rarer breeds, but they should most certainly give classes for Dark and Light Brahmas, for two varieties at least of Game and Cochins, and one for Houdans—the pre-eminently useful table bird, and so on. As it is, we find the money often, especially at southern and midland shows, allotted in such a way as to show clearly that the committee can have no idea of even the existence of many breeds.

We are often asked whether we prefer the single-bird system, pairs of hens and single cocks, or pairs of cock and hen; we can only reply that each division has its *pros* and *cons*. This must be evident to all, so we need not go into them. Perhaps for some reasons the single-bird system is the most highly favoured, as birds can be so sent from any run without fear of being soiled or persecuted by its companion; but the two great drawbacks to this plan strike us as being—first, that a single bird at an exhibition has much less chance of being claimed than if it was with a companion, for ordinarily £10 would not be given for a single bird when £20 would be for a good matching pair, and we must remember these long prices do, to a great extent, keep up the fancy; and secondly and chiefly, we find a society only intends to expend a certain sum of money, and by having classes for single birds instead of for cock and hen, the money is all spent over certain classes, perhaps those in which the committee take most interest, and consequently the remaining breeds go to the wall, and have to meet on that unhappy ground—the refuge for the destitute. We do not for a minute mean to say the same money should be expended on Silkies as on Dorkings or Houdans, but we do think schedules should try to support more than they do the weaker varieties. We must again quote Oxford. We call it a perfect schedule in having classes for nearly every recognised breed, with really handsome prizes and a low entrance fee. We even think in its distribution of its money it is the fairest schedule that exists.

It is important for the larger breeds to be shown when they come to a certain age separately—that is, cocks separate from hens; but for the smaller breeds and Bantams it is not nearly so necessary. We would, then, recommend a schedule being divided into two parts. In the one we would place Dorkings,

Brahmas, Cochins, Malays, and Game for their fighting propensities, and perhaps the French breeds; in the other we would have Hamburghs, Polands, Spanish, Leghorns, Silkies, Andalusians, and such like, and all breeds of Bantams. The first part we would have for single birds, or cocks and pairs of hens; in the second cocks and hens together. We fancy we should thus have more entries, please all exhibitors, and divide the prize money more fairly. Of course at such leviathan meetings as the Palace, and anywhere else where there is plenty of space and money to lay out in prizes, the classes can be divided off even yet more for single birds. For all ordinary exhibitions, however, such a classification as we name would, we think, meet all ends. For instance, Northampton has a superior schedule, one which does Mr. Humphreys and his colleagues much credit; but if some such division as we name had been in existence there the extra money gained by putting the Hamburgh, Bantam, and such like cocks and hens together, would have enabled them to give more classes for Dorkings, and a class for Polands, Black Cochins, &c., which would have made their exhibition more complete, and not have decreased, we feel sure, the amount of entry money.

For the early chicken shows cockerels and pullets have generally to be shown together, for there are very few societies which hold their meetings in July, August, and September that can afford so many classes as the single-bird system entails, and so they must have pairs; but even these can apportion their money more fairly among the different breeds by better classification than they are in the habit of doing. Perhaps, however, it does not matter so much with those birds to be shown singly, for they have generally lived on stimulating foods to push them on for early showing, and the continual moving about from show to show checks their growth and entirely unfits them for any chance of being able to take part in the later and more important exhibitions. These birds thus shown about are very rarely of any good afterwards, and by the end of September have had their day. We are, of course, here speaking of those birds which go to show after show during the hot summer months. We feel certain nothing is so bad for a bird as to be exhibited before it is naturally matured and filled-out. We can quote many cases when being exhibited only once while in a growing state has checked the growth of the birds from that date.

While on the subject we must say a word on classes for pairs of hens or pullets. We know they are not fashionable, but we have a great affection for them. We have the most pleasing recollections of buying our first hens in pairs at a show, and now we find but rarely opportunities of doing this. We think these classes should still go on. Undoubtedly a pair of hens in a pen are much more attractive than is a single one; but apart from this we are unable to buy a pair of birds that match and suit our requirements, for it always somehow seems unsatisfactory to buy one bird, and very likely give as much for it, if we feel we must have it, as we used to give for a pair. The single-bird system has in many cases checked the number of pens sold at an exhibition, and we do not wonder at it. By all means we say separate the cocks from the hens in the large breeds, but do let us have sometimes an opportunity of seeing as well as buying a really well-matched pair of hens or pullets.

One more word in conclusion as to classes for the "abused" breeds. We feel Leghorns, Minorcas, Sultans, Silkies, Black Cochins, and even Malays and Polands should have more attention paid to them. We must remember, though the leviathan exhibitors do not generally go in for such "small deer," still their admirers are people who work hard for the fancy, and help in no small degree to make up its very backbone—people, too, who spend their money nobly on their pets, for we know of a gentleman who gave £10 10*s.* for the first Palace Silky cockerel, and £10 10*s.* would buy a good Cochin or Brahma, and is an unprecedented price for a Silky. Surely, then, such fanciers should be supported, and we confidently hope we shall gradually see more classes, till at length a "refuge" will be hardly needed.—W.

HOUDANS LAYING.

Last June I purchased several Houdan chickens. They were easily reared, and in every respect I was much pleased with this breed. Five of the pullets were put on a run with a cock of 1873, the cock being no relation whatever to the pullets. I was much surprised and disappointed by the lateness with which the fowls in question commenced laying, not one egg having been laid by them three weeks ago, although now they are in full lay, and lay so remarkably well that they are helping to make up for past deficiencies in that respect. I think the Houdan a very useful fowl, but I should like to see it a much earlier layer than it is with me. The experiences of the correspondents of the *Journal of Horticulture* have been very interesting to me, and also, I doubt not, to many others who have read them.—Walter B. Arundel.

My friend, "D., *Deal*," asks for our experience with Houdans as layers. I have now had them for five years, and I grow more fond of them every day. My birds lay well. My two pens of prize birds, consisting of five hens or pullets in each pen, are now averaging nine eggs a-day. They are confined in runs 35 feet by 12; and they have been laying since the first week in February. Of course the average during that month was not so great, but still good. I have some birds running quite free, and they have been laying well since the end of December. Does not "D., *Deal*," overfeed? I feed but twice a-day.—E. Handley, *Glastonbury*.

DREAMS OF A POULTRY FANCIER.

Reader, do you ever suffer from the visits of nocturnal hens? Do they ever pay you a flying visit? Did you ever, for instance, in your dreams go to remove that last promising hatch from the sitting house, and, putting your hand into the nest for the chickens, feel twining round your fingers thirteen cold but lively young snakes? Or did you ever observe that large grey tom cat sitting in the coop with your chickens, and playfully scratching the back of your best cockerel with blood-stained claws? Perhaps your disordered imagination never prompted you to try and lift up one of your coops to put it under shelter during heavy rain; but if it did, no doubt you found it stuck so tightly to the ground that your most frantic efforts failed to move it. How the rain beat down on your perspiring head! and how you struggled and pulled until, with eyes starting out of your head, you suddenly felt the top of the coop give way, and found yourself rolling in the mud, horror-stricken at the thought that all your chickens were either crushed in the ruins or drowned by the deluge! What a horrid cackling the old hen makes as you start up to find that the alarum is going off, and that it is time for you to turn out to feed your early chickens.

Reader, if you are a fancier, and yet your breathing has never been oppressed o' nights by heavy hens; if your disordered digestive organs have never given birth to feathered monsters; if your excited brain has never been over-run with broods of starving chickens—be thankful. Perhaps they have dealt with you more kindly, for these birds of night, I feel bound to say, can make themselves agreeable when they like. It has been my lot on more than one occasion to have first prizes and silver cups awarded to me by proclamation during the witching hours of night.

It was not long ago that I appeared to be called upon suddenly to pack up one of my champions, and in company with another fancier, who also had his hamper, to proceed to a distant poultry show. Our conveyance was an outside Irish car, and great was our solicitude for the two hampers which contained our precious specimens; and as we had not seen each other's birds, many were the speculations as to which of us would carry off the champion cup. I confess that I felt an overweening confidence in my own production, and still remember the feelings of triumph and conscious superiority with which on arrival at the show I cut the string and threw back the lid of my hamper. As I lifted out my treasure, which in appearance resembled a very pretty six-year-old child dressed in a white frock and blue sash, did I manifest any surprise? Not in the least. Such paltry considerations as the differences between birds and little girls in blue sashes are quite beneath one on these occasions. And as my friend produced another little girl with a red sash, but of a lankier and leaner description, my exultation knew no bounds. I felt sure of the cup, and was quite sorry for my friend, who, with crest-fallen look, leaned on his hamper as our two competitors proceeded to pen themselves in their respective cages. I am much ashamed of myself 'tis true, when I find that in divesting myself of my dress I am unable at the same time to lay aside the thoughts and cares that enwrap my brain by day for the more suitable nightdress of oblivion. But so it is. Tell me what you do by day, and I'll tell you what you dream of at night. So now that I have disclosed my night vision you can well guess what gives rise to them. And is there not a cause?

Did you ever, my friend, look with pride and pleasure on the tenants of your poultry-yard? Did you ever, after careful study of their various points, divide them with a view to future increase, and wait with patience for the fruit of the union? and after a cold and dreary December congratulate yourself on a mild January, which enlarged the combs of your hens and painted them of a deeper red? Did you watch eagerly for the first egg, and finding it, bear it off in triumph? Did you collect these priceless embryos slowly day by day from your choicest birds, and as the number multiplied think that, this year at all events, you would whip creation? Did you scour the country for broody hens, and after much trouble and expense secure two? Did you carefully make-up their nests in warm corners, and commit to them these precious eggs, which you remark are worth a guinea a-piece? Did you retire that night to your virtuous couch and reflect that at all events you had done your share towards your future anticipated success? Did you for twenty days carefully watch over and tend those hens and eggs, and for twenty nights have sweet visions of silver cups and £20 notes? Did you on the twenty-first day go to your nests

with a beating heart to find out how the hatching was proceeding? Did you feel a sudden revulsion when you found only one egg chipped? Did you say to yourself, "It's the cold weather, they will be sure to hatch a day late?" Did you leave them until the evening? and did further examination then disclose to you the painful fact that your two sittings would in all probability present you with the magnificent result of one chick? Did you go next morning and find that one chicken strong and lively, disporting itself on a pavement of addled eggs? Did you meditate on its destruction, but conclude at last that you would not wring its neck, as it might be a good one? Did you feed that small and solitary chicken patiently all that day, and in the evening eat a heavy supper previous to giving him his night meal? Did you set your alarum with a gloomy countenance, and reflect that you would have to turn out early next morning and every morning for some time to come to feed your charge by lamplight? Did you bless the day on which that chicken was hatched, and lie down to rest? To rest! did I say?

My friend, watchful eyes have been upon you. This is an opportunity not to be missed. This night shall high jinks be performed on your prostrate body by ghostly cocks and hens. This night shall that chicken which is "one" by day multiply itself ten thousandfold and sit in every corner of your distracted brain. And as you wake up from your troubled slumbers, scared and thirsty at the sound of the alarum, the bitterness of your lot will be still further increased as you remember that you have not been able to sit any other eggs, and that consequently it will be at least a month during which you will have to dance attendance upon your solitary chicken.

Moral.—Don't write and abuse the person from whom you purchased your sitting of eggs in January or February because you have only three chickens from them. Be assured that the vendor would esteem himself fortunate if he could make sure of securing as many from each of his early broods.—R. W. Beachey.

A COLUMBARIAN SOCIETY FOR LEEDS.

Owing to the increasing interest in the cultivation of high-class Pigeons in and around the town of Leeds, it has long been felt by the leading fanciers of that locality that a society of the above description would be of great service. In furtherance of this opinion, on Tuesday the 6th inst., mainly, we are in justice bound to state, by the exertions of Mr. E. Mawson of Moor Allerton, a meeting was convened at Parker's Temperance Hotel, when Lieut.-Col. Child occupied the chair. The following officers were elected—viz., Lieut.-Col. Child, Leeds and Arthington, President; Capt. Dawson, Weston Hall, Otley, and Mr. S. E. Seanor, 26, Springfield Place, Leeds, Vice-Presidents; Mr. E. Mawson, Moor Allerton, Leeds, Hon. Secretary and Treasurer. After a brief discussion it was decided the title be "The Leeds Columbarian Society." The Society starts with a list of about thirty members.

The Number of Eggs in a Hen.—A German naturalist a short time since instituted some careful investigations, the result of which showed the ovary of a hen contains about six hundred embryo eggs. He also found that some twenty of these are matured the first year, about 120 during the second year, 135 during the third, 114 during the fourth, and during the fifth, sixth, seventh, and eighth years the number decreases by twenty annually. Consequently that after the fourth, or at most the fifth year, hens are no longer profitable as layers, unless it may be in exceptional instances.

FOREIGN TRUMPETERS.

In "Wiltshire Rector's" last article on Owls, &c., he states that "unfortunately foreign Trumpeters do not breed in England." This I was quite surprised to hear, as a fine pair which I received in the autumn of 1873 bred last year seven young birds, five of which they reared themselves, and six of them are still alive in my possession. This season they have made a beginning, as they are sitting on a pair of full eggs. This, I think, is quite equal to the breeding powers of the old style of birds which I kept for many years. I do not think it can be the climate. The winters in their native country are, no doubt, colder than here, but their summers are quite as warm as ours, I believe even more so; but I do not think there is sufficient difference to affect their breeding powers, neither should the very slight difference between the climates of England and Scotland affect them. Mine are among my Pouters and have no special attention, but potter about in their peculiar groping sort of way just as they please. They look stupid birds, but are not so in reality.—Geo. Ure.

In reply to Mr. Hutchinson, what I said about foreign Trumpeters not breeding in England I had from a very distinguished exhibitor of that class of Pigeons. He stated that he could never induce two true foreign birds to breed, but that one English-bred and one foreign would do so. I do not like without his permission to mention his name, but if Mr. Hutchinson will send me his address through our Editors I will do so privately to him, as no doubt he would be glad to hear of Mr. Hutchinson's plan. I rather suspect that the birds that bred were only partly foreign.

The Russian Trumpeter is a grand bird. The first I saw were a pair at a fancier's since dead, at a town on the east coast of Scotland, and he had brought them from Archangel, a port on the White Sea, the very northern part of Russia. They were called by their owner Russian Pigeons, but unless my memory deceives me they were simply and truly very fine Trumpeters.

I am glad Mr. Hutchinson agrees with me about the Dragoon. There can be no difference of opinion about that bird by fanciers who have studied the old authorities.—Wiltshire Rector.

FEATHERS OF THE SILVER-LACED BANTAM.

The hackle feathers (fig. 69), from the smallest to the largest, have the same mark, with a light border. Those of the neck

Fig. 69.

Fig. 70.

and breast (fig. 70) are very regular in their marking; as are those of the back, shoulders, and the tail coverts (fig. 71). Those

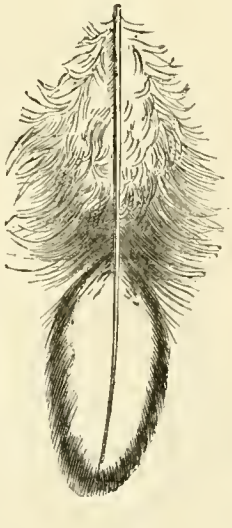

Fig. 71.

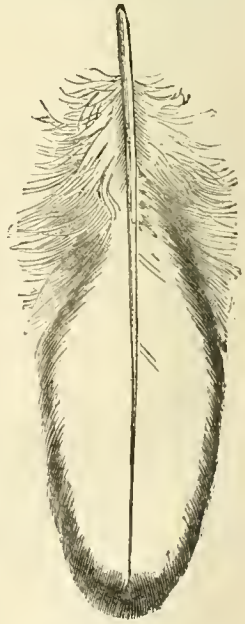

Fig. 72.

of the wing coverts have the stripes narrower (fig. 72); also the

large feathers of the wings and the tail (fig. 73). Those of the thighs (fig. 74) have the stripes broader, and they are altogether

Fig. 73.

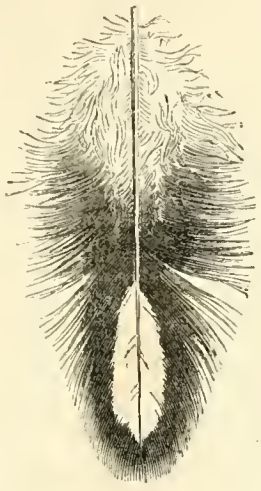

Fig. 74.

darker. The feathers of the abdomen and sides are of a mixed grey.

THE ENGLISH OWL AND MAHOMET PIGEONS.

"Wiltshire Rector" gives his opponents a sugared plum to encourage them to go on. Having received one of his plums I therefore proceed to mention some ideas suggested by the Rector's last.

Eaton in his book quotes the writer of the Treatise of 1765 as Mayor. For shortness I shall do the same. I do not consider Mayor is wrong in his quotation about the size of the Owl, for although it is, as Mr. Tegetmeier says in his book, the size of the Turbit that Moore gives as little larger than the Jacobin, he immediately afterwards in the few words devoted to the Owl says, "This Pigeon is in make and shape like the former (the Turbit). Things equal to the same thing are equal to each other."

The Rector is too hard on Mayor when he says, "The former quotes Moore throughout without acknowledgment, which is the conduct of a dishonest man." Eaton also attacks him, saying, "I am rather surprised Mayor had not a little more candour or honour in acknowledging Moore, from whose works he cabbaged the greater part of his work; he simply mentions his name twice throughout his work"—viz., at pages 125 and 141. We shall see further on that Eaton himself was an accomplished cabbager Instead of mentioning Moore's name only twice, I find on a casual look through the book that Mayor mentions it eight times; and further, from what is original in his book, I judge him to have been a Pigeon fancier of the right stamp, whatever Girton *alias* Thompson may have been. Perhaps Eaton's copy of Mayor was mutilated and imperfect, or perhaps it may have been the small paper edition with simple woodcuts, and not the large paper one with good steel plates, which the Rector tells me privately I am the fortunate possessor of. Not yet having a copy of the small paper edition I cannot say whether or not in it Moore is only named twice. Certainly Eaton was a painstaking careful writer, and to be trusted to transcribe what he read. This is what Mayor says in his preface page xiii., "In regard to the model of this Treatise we do not offer it to the public as an entire new work, but have proceeded on the plan of Mr. Moore, have corrected some errors and made many additions with extracts from other authors; and as Mr. Moore's essay is very deficient for want of cuts to convey a just idea of the different species, in order to supply that defect we have procured engravings from the best hands at a very great expense in order to illustrate this work, all which are done from the life, and very masterly executed under the inspection of the author and other fanciers." He here lays claim to being more than a "bookseller's hack," and writes much on the Almond and other Tumblers, Owls, Mahomets, Lace Pigeons, and Frillbacks, that is all original.

Although Mayor mentions Moore much oftener than Eaton gives him credit for, Eaton himself published his Almond Tumbler in 1851, three-fourths of which is copied verbatim from Windus, and he never mentions his name once, or, supposing he did not know his name at that time, the existence of the book published in 1802 by "An Old Fancier." In his subsequent publications of 1852 and 1858 Eaton takes Moore as his text, adding notes of his own and writers between Moore and that time. But in each of these books he reprints his Almond Tumbler with very slight alterations, not taking Windus as a text, and adding notes of his own to show what he was entitled to, but in such a way as to make the reader believe that all was his own. Those having the Almond Tumbler of 1802 and 1851 can of course see what belongs to each writer.

As to the Owl of Moore's time all he says about it is, that "in make and shape it is like the Turbit, except that the upper chap of its beak is hooked over like an Owl's, and whence it has its name. Its colour is always entirely white, blue, or black." Mayor gives a much fuller description, includes yellow among the colours, and mentions "a fine sky blue, and the lighter they are in colour, particularly in the hackle, the more they are valued." This to my mind is the colour known as powdered blue, and I am therefore satisfied that this colour has been known in Owls for 110 years. I have a theory how it was produced, and will mention it further on. I do not think that Moore ever saw such birds as the fine African Owls now imported, or he would have given a very different description of them; also, had there been Powdered Blues then he would have mentioned them. By Mayor's time, however, I think some of the Africans had been imported and put the old style in the shade, so particularly does he describe birds that answer their description. But unfortunately his plate of the bird does not answer his really good description. If birds of the right stamp had been imported it must have been in insufficient numbers to perpetuate the fine style, or they must have been lost ere long by carelessness.

The colour powder blue, when I wrote some weeks ago, was in my opinion confined to the Owl Pigeon. I strangely forgot the appearance of a bird I saw last year in Mr. Wallace's place in Glasgow. This was one of a pair that had been brought, I think Mr. Wallace's son told me, from Constantinople, and which as far as I can remember it, corresponds exactly with the Pigeons called Damascenes, figured in No. 11 of Mr. Fulton's new book. These birds appear to me to be what Mayor describes as the true Mahomets, as opposed to Moore's statement that the Mahomet is a White Barb. Brent also says he once saw a pair of them at a London dealer's (Eaton, page 102). Mayor calls them "nearly cream-coloured with bars across the wing as black as ebony, of the size of a Turbit, with a fine gullet, and in lieu of a frill the feathers rather appear like a seam with a small naked circle of black flesh round the eye and a small black wattle." There seems no doubt that the African Owl is in colour only white, black, sooty, blue or white, splashed with black and blue. They seem to have been all interbred, colour being disregarded. From a blue-tailed white hen and a black-tailed white cock I bred pure white, all dark blue and whites splashed with blue and black. Anything approaching a sky or powdered blue I never saw in African Owls that were really fine ones. I think, therefore, that the Powdered Blues were produced by crossing with the Mahomet, as described by Mayor, which is not a proper cream-colour but so light a blue that the dark neck accompanying blue Pigeons is entirely absent, and a creamy appearance takes its place, the bars remaining black as ebony. From old association however, I like the powder blue in Owls, and repeat that could it be engrafted on birds so fine as the Africans it would suit them well. I fear, however, it never will, for the dusky colour of the African destroys it at once; and a breeder would be so far away in head, beak, and size as to lose heart. But though not probable it is possible, and patience may accomplish the work.

The Rector's theory of the climate is not to my way of thinking. Cold countries do not increase, they rather diminish size. The heaviest birds among Pigeons are the Mediterranean Runts. The Russian Trumpeter looks a large bird but does not handle so, being all feathers. I can remember and have had Trumpeters of the old type half as heavy again as the largest Russians; I know of one pair of Russians that bred six or seven young birds last year and all fine.

The African Owls, the Turbiteens, Blondinettes, and Russian

Trumpeters are all illustrations of the power of mind over matter. They are the masterpieces of grand fanciers, and put us to shame. In charity let us suppose we never had good of the kind to begin with, but to crack up our own miserable half-bred or deteriorated things is what I cannot do. If flyers are wanted better can be had than coarse Owls, one of the funniest of Pigeons.

We have at least three breeds of our own—the Pouter, Carrier, and Short-faced Tumbler. These grand Pigeons seem to have no attraction for many who spend their money (which is nothing, as it only goes from flat to sharp), and precious time (which is something, for it might be devoted to better work), on Dragoons—save the mark—about which no two can agree as to what they are, Short-faced, Antwerps, and the like.—JAMES C. LYELL.

[We have omitted the vituperation you wrote relative to the plagiarism on Fantails by "E. C. D.," in a contemporary; we have omitted it because we informed the editor that another correspondent had noticed the plagiary, and the editor in his last number has made a due acknowledgment.—EDS.]

TOY PIGEONS.

AFTER the common Pigeons the Toys, or birds noted for combinations of colours, were the earliest succeeding links in the chain of varieties of Pigeons. In the development of art colour was the first thing of interest to the ancient savages, just as now it first attracts the child; this comparison is a just one, for the æsthetics of the aborigines were no more developed than are those of a child of the nineteenth century. An ordinary amount of intelligence is pleased with colouring; it requires education to notice and appreciate special points, such as heads, beaks, crops, &c. Therefore, in the earlier days of mankind and Pigeon fancying, colouring was the attraction; certain Pigeons were kept because of their being sports of different markings from their ancestors; thrown together they produced other sports, and so varieties of Toys were produced.

Almost every boy whose opportunities are few to obtain varieties, grows (in a small way) through precisely the experience of the whole human family, in its efforts to develope the varieties. As the life of an individual is really the life of a nation, so is the life of a fancier really an epitome of the world's Pigeon fancying. As in childhood he is pleased with a common, then a Baldhead common, until he can procure Toys, fancies, and at last high fancies; so the human family first kept their commons, then selected the sports, and finding from experience that two birds looking alike might produce their like, took pains to match such together, and so developed colours or Toys, until some trait, as tumbling, accidental at first, or ponting, or increased wattle, turned their attention to and produced more intricate differences. Each fancier grows through these eras, unless he starts late in life and founds himself on the books.

Toys are, therefore, the first removes from the commons, and those parts of the Pigeons that are easiest to change were undoubtedly the first distinguishing marks; white tails and flights, then white heads, wings, breasts, &c., at last the perfect white bird. After such markings were admired for countless years, varieties became fixed, certain combinations of colours were looked upon as standards, and names were given to such.

The names prove more conclusively than any other source of information at what era certain varieties were acknowledged to be sufficiently fixed to be entitled to that distinction. The name Nun, as applied to Pigeons, shows that the variety was named because of a fancied resemblance to the head-dress of a religious devotee of the Catholic Church; therefore, we can set the variety down as having been developed since the establishment of catholicism. So of the Helmet, from Anglo-Saxon derivation, not only proving the variety to have come into existence since the use of helmets in war, but also pointing out its birthplace.

Most of the Toys can be traced in this manner to an era and a birthplace, and many changes have been noted in the class and in the different varieties of the class. Not only has the class been increased by additional numbers, but the varieties have been subdivided into blacks, reds, yellows, blues, &c., until combinations of any kind can be obtained; or when not immediately obtainable, can be bred. The birds that rank as standard varieties are Suabians, Archangels, Hyacinths, Porcelains, Starlings, Nuns, Priests, Spots, Swallows, Magpies, Helmets, and Ice Pigeons. From this list a fancier can choose those he wishes to breed. As standards, or to cross for new specimens, none of them breed perfectly true. No matter which you take, there will always be some of the young that turn out foul; and nothing is a surer proof of their common ancestry than that the foul young are of no more worth in appearance or value than so many commons.

After Tumblers became known that trait was engrafted upon the more ancient Toys, and not many years ago there were Magpied, Helmeted, and Nun Tumblers; and these varieties can again be reproduced by matching proper specimens of the Tumblers and Toys together, selecting the well-marked tumbling young as nuclei for the strain. Any enterprising fancier can multiply the strains of Toys *ad infinitum*; but it is not every Toy fancier that can handle successfully the fancies or high fancies, each of which definition supposes a higher degree of excellence in the Pigeons designated, and a greater knowledge on the part of the fancier admiring.

The Toy fancy is but the entered apprentice degree; the fancy that of fellowcraft; and the high fancy ranks as the master degree.

One may understand both the first and never rise to the dignity of the last; but one cannot know thoroughly the last without holding the first as a mere stepping-stone on the road to knowledge.

There may be a few readers to whom it should be told the Toys refer to Pigeons whose sole value consists in one point—colour, properly distributed upon a designated ground colour, which is generally white. The fancies refer to a large class having more than one point, such as Owls, Turbits, Fantails, &c.; and high fancy but three varieties, whose intricate points are numerous and difficult to obtain—viz., Almonds, Carriers, and Pouters. One or two varieties, such as Barbs, might be entitled to a place in the latter class, but are not as yet so recognised.—DR. WILBUR P. MORGAN, *Baltimore, Md.*—(*American Fanciers' Journal.*)

[If Dr. Morgan does not always throw new light upon a subject, he at any rate always throws additional interest around it; sometimes indeed he does both. Toys appear to be more generally fancied in America than in England. In this we see the leading characteristic of each country—England holds to the old, America attaches itself to what is new. With us a boy fancier obtains common Tumblers or interior Pouters, but his desire is, or will be, to have good Tumblers and good Pouters, Toys are unthought of. I think that with us it is rather wealthy and adult fanciers take to Toys.

Dr. Morgan is no doubt right that Toys are the first removes from the common: thus the dovehouse beak and form is retained by one of the oldest Toy Pigeons—viz., the Nun; and it would be a pretty theory that the boy fancier is the Toy fancier, but untrue now with us, for the old gentlemen—the bald, the grey, the portly, or the shrivelled, are mostly given to Toys. The solemn and somewhat pompous announcement in old Moore at the end of his article on the Runt, "The following sorts of Pigeons are generally deemed and called Toys by the gentlemen of the fancy," rather points to the conclusion that in his day the upper-class fanciers only cared for Carriers and their kindred the Horseman and the Dragoon; the Pouter and his kindred, the Parisian and the Uploper; the Tumbler in his many varieties, and the three varieties of the Runt. And I suppose that the grandees of the fancy sniffed at the poor Toys and their owners. This was very absurd, for certainly the Barb and the Jacobin and the Fantail are as beautiful and as distinct, and as far removed from the common type as the Carrier, Pouter, or Almond. Brent, with his good common sense, includes the Fantail, the Jacobin, the Trumpeter, the Turbit, Owl, Barb, and Frillback, among high fancy Pigeons, and makes the Toy list to include only Pigeons having the common shape with variations of plumage, and this I fully agree to. Dr. Morgan ingeniously connects the names of some of the Toys with the time of their first cultivation.

I would certainly give the older Toys the highest place, for two reasons. First because they are oldest, and secondly because they breed the more true; for oh! the foul feathers that come in the best Toys! what gardening they have before they are exhibited, and how unlike often their young are to themselves! As Brent and Dr. Morgan divide Pigeons there is no cause to complain. The high fancy birds give the most trouble, but success in them wins the highest rewards of pleasure perhaps, and certainly of money.

The fancy give much pleasure with much less trouble, and suit those who cannot be much at home with their pets, or who have no trustworthy substitute to see to feeders, &c. And the Toys according to Dr. Morgan's arrangement just suit some ladies who have an eye for feather, or those who love the new or think they can win a prize in the Any variety class. Also there are certain minds which are greatly attracted by Toys, and it is well, for in England they would cease to be cultivated but for a few ardent feather-loving fanciers.—WILTSHIRE RECTOR.]

LIGURIAN VERSUS COMMON BEES.

As one whose hobby is bees I hope you will allow me to protest against Mr. Hunter's suggestion to set aside the proposed trial side by side of Ligurian and Black bees. I am one of the doubters as to the superiority of the Ligurians as honey-collectors, and do not see the logic of Mr. Hunter's argument, that because Ligurians are more prolific breeders they are therefore better honey-collectors by virtue of their being more numerous. Is it not possible that one kind of bees go in more for swarming, another more for honey-collecting? The former is the

opinion which I have formed of Ligurians, the latter of our old friends, and this chiefly from what I have read of them for some years in "our Journal."

I should like to be informed, for I do not know, what kind of bees inhabited the twelve hives which produced the 907 lbs. of virgin honey exhibited at the Crystal Palace Show.

I only desire the trial in the interest of science, and of the increasing number of bee-keepers. Till the matter is thus satisfactorily proved I shall look upon Ligurians as a fancy of the day, a mere fashion, and remain—UNCONVINCED.

RUFFED AND PINNATED GROUSE.

As your correspondent "A. H. B." alludes to these two species of American Grouse as if they were identical, he cannot have read Wilson with much care. The above-mentioned birds are entirely distinct, and do not frequent the same districts or the same nature of ground. The Ruffed Grouse (Tetrao umbellus) is a woodland bird, having the habits of our Pheasant. The Pinnated Grouse (T. cupido) frequents the boundless grassy plains of America, and is commonly called the Prairie Hen. It much resembles our Black Game in its food and choice of ground.

I am much surprised that anyone having access to the public papers should not have observed the numerous trials of late to introduce this delicious and hardy Game bird. One Sergeant Bates of Illinois—who distinguished himself some time since by walking through England bearing the American flag—wrote in the *Field* and other papers about a year ago that he could send any quantity over, if he had an order, at about 10*s.* a couple. He also wrote me a long letter on the subject, which I took up warmly, and sent him a long list of noblemen and gentlemen anxious to try them on an extensive scale. I also suggested sending over sound eggs, and he sent me nearly a hundred, evidently gathered fresh and well packed. These all failed for many reasons: They were above a month on their journey; they were several days in the custom house at Liverpool when the weather was tropical—sufficient to addle anything of the sort. I kept them under hens for a month, and on examination found the yolk had adhered to the sides for want of turning, which is indispensable.

I am positive that eggs might be brought over with their vitality retained if skilfully managed, as we have well authenticated instances of their being kept for months and then hatching (*vide* Jesse's "Gleanings," &c.). Some eggs sent at the same time to the Prince of Wales brought out, but the chicks did not survive, being weakly. I do not see why Mr. Baily in particular should be applied to when Mr. Jamrach advertises them for sale. He had a fine lot last year, which were picked up immediately. Those which my personal friends had from him all died; they would not endure the confinement of an aviary when spring with its natural attendant impulses arrived, but became uneasy and pined away. Mr. Jamrach also advertised several pairs in the early part of this year, and may have some yet. I dared not venture to take any at the time, as we have had the severest winter on record, and there was no shelter or food to keep them within bounds.

Prairie fowl are great ramblers in quest of food and frequent open ground; Ruffed Grouse, on the other hand, fly into the nearest wood or thicket on being disturbed. This habit makes them the more desirable bird for us to introduce.

They are now extinct in many States of America, where they abounded in the days of Wilson and Audubon. The latter had a great quantity of both perfectly domesticated at his home in Kentucky. The only chance of success with Prairie Fowl would be to introduce them on a large scale, so as to leave a good margin for accidents and on a large domain of land.

The best account of recent date of these birds is to be read in "Gun, Rod, and Saddle," by Parker Gillmore, who knows my part of the country well, and insists that both Prairie Fowl and Ruffed Grouse would do well in many parts of the north of England and Scotland.—J. GILLBANKS, *Cumberland.*

THE PRIZE CAGES AT THE CRYSTAL PALACE BIRD SHOW.

SECOND-PRIZE CAGE.

THIS cage (fig. 75) met with the approbation of the Judges, owing to the suitability of it to show a bird effectively. It is simple and light, with no ingenuity in the make of it. It also answers the purpose of showing a bird well both during daylight and gaslight; the only drawback being that the vessels for seed and water would have to be made a separate package or unless they were placed inside, which is no improvement upon the present system. The cage was exhibited by Mr. W. Evans, and was awarded the second prize. The number in the catalogue is 1453, but the cost of construction is not stated; but it would be more reasonable than the first-prize cage.

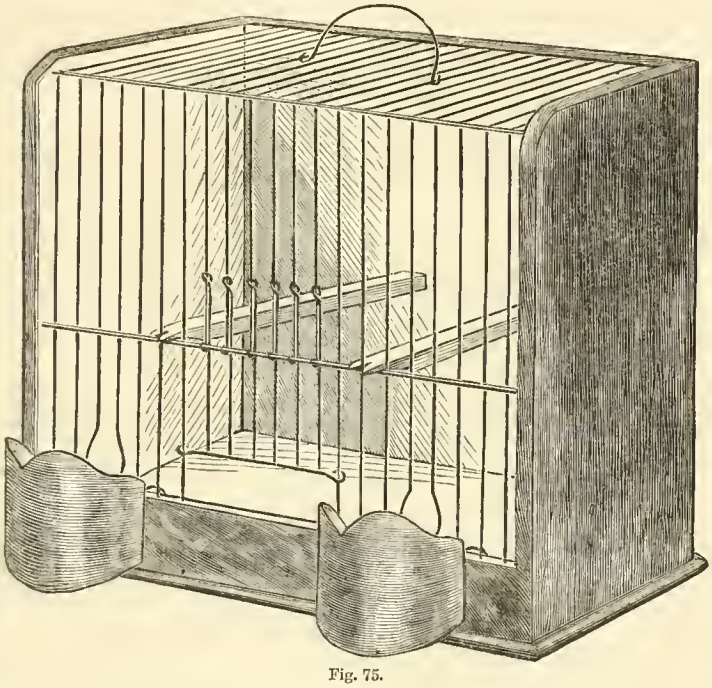

Fig. 75.

THIRD-PRIZE CAGE.

The cage numbered 1449 was not so generally approved, it being rather too small. Still this could be obviated, and the construction of it maintained. It would make a tolerably good show cage with slight alteration, one fault being that it is too deep from back to front. The catalogue states "the back of the cage screws off and on, so that it may the more readily undergo a regular cleansing." The vessels for seed and water are made to insert at each end of the front of the cage, and the wirework is turned inwards, so that the vessels can be replenished with food. The cost is stated to be about 3*s.* 3*d.* It was exhibited by the Rev. V. Ward of Hythe, Kent, and was awarded the third prize.

Altogether forty-seven cages were exhibited, some of which were tolerably good in construction. Several were far from being adapted for show cages, they being too intricate. Mr. T. Newmarch of Shoreditch and the Crystal Palace entered no less than seventeen, styled as follows:—Stag's Head Cottage, New Design, the Princess, the Gothic, the Emperor, the Optician, the Latest Style, the Snow Fall, the Acorn, the Count, the Pagoda, the Inlaid Pagoda Brass Wire (2), the Jenny Lind (2), the Stained Corner Brass Wire, and the Brass Wire Domed.

YORK AND DISTRICT FANCY RABBIT SHOW.

THE annual Spring Show of the York and District Fancy Rabbit Club was held on the 3rd inst., in the large room in the Friendly Society's Hall, Castlegate, where some first-class Lop-eared Rabbits were exhibited. The first prize and silver cup for length of ear was awarded to Mr. Dobson's Grey-and-white doe, with ears 22½ inches long by 5¼. This Rabbit also carried off the first prize for heavy weight, it weighing over 12 lbs.; it was also awarded the extra prize given by the President, Mr. Hume, for the best all-property Rabbit in the Show. It is a grand all-property Rabbit, and the condition she was shown in was a credit to her breeder. Mr. Dobson also took the first prize in the Black-and-white class with a good Rabbit well marked. The second prize was won by Mr. J. Wharton of Bramham with a very nice Rabbit. In the Yellow-and-white class Mr. Wharton took the first prize with a very nice well-marked buck. The second prize was awarded to Mr. Kittlewell for a good all-property doe. In the Grey-and-white class Mr. J.

Wharton, Bramham, took the first prize, and Mr. J. Wharton, York, took the second. In the Tortoiseshell and Blue-and-white classes there was no competition; Mr. Wharton took the prize in the former class, and Mr. Myton in the latter with two very fair Rabbits. In the Self-coloured class the competition was very keen, for all in this class were very good Rabbits; the first prize was awarded to Mr. Wharton for a grand Fawn doe, and the second to Mr. Myton for a very fine Fawn buck. The above two Rabbits divided the second prize for length of ear. Mr. Wharton also carried off the President's (Mr. Hume's) prize, given for the best eyed Rabbit in the Show, with a very fine young Grey buck.

The Show was well attended. Mr. Hume and Mr. Thornton were the Judges.

EGG VENDORS.

In your last number "W." seems to infer that most, if not all, egg buyers are unreasonable, and some dishonest. I think, however, that occasionally the egg sellers are open to criticism, as last year I bought a sitting of White Cochin eggs from one of the most successful exhibitors of that variety. Nine of the eggs were clear, three hatched, one produced a fairly good White Cochin pullet, the other two eggs inferior cockerels—a Buff and a Grouse. I unpacked the eggs myself; had no Cochins of any kind at the time, nor were there any in my neighbourhood. I remonstrated, and was civilly informed that it was a case of "reversion." I was offered a White Cochin cockerel to console me for my ill luck; which cockerel, however, has, up to this time, never arrived here.—J. H. Hutchinson.

CHILLED BROOD.

The present prospects of bee-keepers are lamentable, I fear, and abundant as may be the harvest in the fields, there must be a lack of bees to gather it in. Mr. Pettigrew has sounded the note of alarm, and well he may, for now is the middle of April, and we are still in winter, with a cold north-east wind blowing. Neither yesterday nor to-day did a bee stir in my apiary, nor have I yet seen a single young bee, and we have reached the time when they are usually seen in considerable numbers. Chilled brood, therefore, is not unlikely to be found in very weak hives. I suppose this is what Mr. Pettigrew means, and that which he advises us to cut out of our hives. But he seems to confound chilled brood with foul brood, which is a very different thing. I do not say that chilled brood may not sometimes be the cause of foul brood; but there is no inevitable connection between the two, the latter being a most virulent pestilence, destroying hive after hive, but happily not common in England; whereas the chilled brood is of very common occurrence, and easily cured by the bees themselves, as I have proved myself many times. It may be advisable to assist the bees by cutting out such brood, which, however, is not usually, if ever, found in the centre of the combs, but on the outskirts; as when on the sudden change from very warm to excessively cold weather, the bees draw in their forces towards the centre of heat, and the outer combs become deserted. I very much doubt whether chilled brood is to be found in any moderately strong hive this year, for the simple reason that the queens have not been tempted to lay eggs far from the centre of the mass of bees, or if they have, no life has issued from them. Mr. Pettigrew's treatment is very good as far as it goes for that other plague which may be raging now in some apiaries.—B. & W.

OUR LETTER BOX.

Egg within an Egg (*A. Barnwell*).—For a small perfect egg to be found within one of the usual size is not a very uncommon occurrence. It is an unexplained phenomenon, as are the occurrence of double yolks, three-legged chickens, and two kernels in a nut.

Preserving Eggs (*Agricola*).—They may be preserved in lime as you state fit for use at table; but we prefer placing them in layers alternately with dry salt in a box kept in a dry cold place.

Brahma Pullet Crippled (*J. E.*).—The pullet is egg-bound. Whenever a fowl, either hen or pullet, supports itself Woodpecker fashion on its tail, it arises from one of two things—either a serious injury in the back, or fever of the egg passage that prevents an egg from being laid. It becomes serious if it is not attended to. The cure acts like enchantment, and is as follows:—Pull out a wing feather, one of the largest. Dip it in a bottle of oil, and keep it therein till it is saturated. Then introduce it gently into the egg passage until it reaches the egg. You will have to do this two or three times; each time you withdraw the feather dip it again in the oil. Do not touch the egg or attempt to help the pullet in any other way; you may break it, and that is often fatal. This never fails.

Sick Turbit and Baldhead (*T. G. Simpson*).—We fear your two birds will be dead before these lines meet your eye. We should think that consumption, "going light," is the illness, and that the paralysis of the legs is mere weakness. You have doubtless examined the legs to see if the birds are suffering from the joint being out, or any injury, If alive, and the root of the ailment be internal, give a tea-spoonful of cod-liver oil daily. The food given seems excellent; we give the same to our own Pigeons.

Mr. Fiath's Rabbit (*C. A.*).—We have no doubt all that you say about the Rabbit is correct. As an appeal is to be made to a law court silence is only justice to all parties.

Bar-framed Hives (*T. J. H.*).—Write for particulars to Mr. Abbott, Hanwell, N. Obtain "Bee-Keeping for the Many" from our office. It contains *multum in parvo*. We know of no better or cheaper hives than Mr. Abbott's. See what we said as to "best hives" in last Journal.

Wax from Old Comb (*A Constant Reader*).—Squeeze together your old dry combs, put them into a bag of thin towelling, and boil all in a pot of clean water over a slow fire. The wax will come to the top of the water and appear there as a yellow oil or fat. With a teacup skim the wax off and strain it through a piece of muslin or thin cloth into a vessel. The wax will be improved by being boiled a second time in clean water and strained in the same way. As wax is very inflammable, great care is necessary in preventing it from boiling over into the fire.

Parsnip Wine (*Six-years Subscriber*).—To every 4 lbs. of parsnips, cleaned and quartered, put one gallon of water; boil them till quite tender; drain them through a sieve, but do not bruise them, as no treatment would clear them afterwards; pour the liquor into a tub, and to each gallon add 3 lbs. of loaf sugar and half an ounce of crude tartar. When cooled to the temperature of 75° put in a little new yeast, let it stand four days in a warm room, and then tun it. Mr. Pearson's address is Chilwell, near Nottingham.

REMARKS.

7.—Rain in the night, but a fine morning and a very pleasant day.

8th.—Rain again in the night, but fine in the morning and till about 2 P.M., then dull. Rain commenced between 3 and 4, and continued all the remainder of the day.

9th.—Rain in night and early morning; fair but dull at noon; showery all day.

10th.—Showery and damp all the day.

11th.—A dull though fair day; a few gleams of sun about noon.

12th.—Grey dull morning; and rather dull till 5 P.M., then very bright and sunny; the evening and night very fine but cold.

13th.—A cold but beautifully fine day throughout; very bright night.

The northerly winds continue; but in the early part of the week the long dry period (there was no rain of importance from March 7th to April 6th) was interrupted by a rather heavy fall. Temperature slightly lower than last week.—G. J. Symons.

COVENT GARDEN MARKET.—April 14.

The supply has been better during the last few days, but has not caused much alteration, and rather more inquiry has been made from the provincial markets for articles of general consumption. New Potatoes from Malta are selling at 16*s.* to 28*s.* per cwt.; and Early Ashleaf at prices ranging from 6*d.* to 1*s.* per lb.

From observations taken near London during forty-three years, the average day temperature of the week is 59.2°; and its night temperature 36.6°.

ROSES FOR NON-EXHIBITORS.

DOUBTLESS there are many situated like myself, who are expected to have Roses by the score fit to cut at a moment's notice any time between the middle of March and the end of the year, to whom quantity perforce takes precedence of quality. Quantity we must have; quality we have if we can secure it. It is to those who cannot make Rose-growing a speciality, and who are not able to spend much money on it, that I wish to make these few remarks, principally, in fact, to my brother professional gardeners. Gentlemen amateurs who make Rose-growing their principal hobby must not expect anything I can say about Roses to give them any edification; moreover they do not need it. Most of them grow better Roses in the Rose season and write better English than I do, but just let the month of August arrive, and I should not be afraid to compete with some of them any time from then till the following June.

I may say at the outset that, when I commence to grow plants in quantity which I have previously not had much practice with, I always endeavour not to be dazzled too much by the successes already attained by other growers, as I know this might lead simply to blind copying. It does not follow that because a gentleman amateur has shown the best forty-eight at an all-England show that he can give the best advice to a gardener for producing a perpetual supply of Roses. No one with the least taste can deny the extreme beauty of his flowers in the exhibition stand, but it must be remembered that many of the kinds which produce the most perfect blooms, although called Perpetuals, often do not produce a dozen such blooms in a plant's lifetime. This is sometimes the fault of the variety and sometimes of the grower, who makes his plants live on "high-pressure" system.

What gardeners want are not plants which will bear two or three prodigious blooms the second season of their life and then rapidly go into decline, but such as will produce fairly good blooms in quantity throughout the season, and more of them each year as they grow older. Now this cannot be brought about by the "life-at-high-pressure" system. If a plant or an animal lives too fast it will die all the sooner. The more unnatural the conditions of life the sooner the constitution will give way. Now the natural medium for the roots of a Rose is a tolerably stiff clay, and in that natural medium it will probably continue to flourish as long as an Oak tree. Planted in light soil, made still lighter by the addition of a quantity of manure, it may produce larger petals for a year or two, which in the present day please the exhibitor and the judges, but there is not the texture in them nor yet the colour there is in flowers which are produced on a more natural soil.

The reason why Roses on the seedling Briar are better in texture and last longer than those grown on the hedgerow Briar is that the seedling Briar goes down deep into the earth, and helps itself to more natural and substantial food than the dainties prepared for it on the surface. I suppose no one now doubts the superiority of the seedling Briar; if so, let him cut a flower off it and one off an old-fashioned standard grown in the ordinary way, and compare them twenty-four hours afterwards. Next to Roses on their own roots I prefer seedling Briars; but as it takes considerable time to raise a large stock of either of these, I am obliged to fall back partially on the hedgerow Briar, and will endeavour to give my method of practice.

The Briars with the largest quantity of prickles and not more than two years old, about the size of the little finger, and with green yet firm growth, are selected about the end of September. They are taken up carefully with as many small roots as possible; all eyes and root stems which are likely to produce suckers are cut clean away, and the Briars are planted at once, before they become withered, in the stiffest soil at my command, with no addition in the shape of manurial substances. They are headed back to the required height some time during the winter, and tied to stakes, or a quantity of them are tied to a rail. They are ready for budding the following summer, and if budded as late as July the Briars are left to grow wild, and most of the buds will remain dormant till the following season. I have sometimes budded from forced plants in the end of May or beginning of June; the Briars were then cut back immediately the buds had taken, and sometimes a few good blooms would be produced the same autumn when such flowers were scarce. This, however, is only a makeshift system. I would not have a mop-headed Rose within reach of my eyesight if I could avoid it. My favourite system is to grow Roses from cuttings, but it is a slower system; it takes several buds to form a cutting, and only one to form a standard.

It is surprising how easy it is to grow Hybrid Perpetual Roses from cuttings when one once understands the way of it: the only *sine qua non* is well-ripened wood of the current year. Roses grown in the ordinary way and highly fed do not always produce sufficiently firm growth for striking; but well-grown pot Roses produce the right sort of wood in abundance—wood which cannot help striking. My cuttings are put-in at the end of October or beginning of November in the open ground where it is rather gritty. A trench is made as if for laying a Box-edging, and in this the cuttings, which have at least three or four eyes, are placed about 4 inches apart, with only one bud above the ground, a little soil is placed against each cutting to hold it in position till the line is finished, when it is filled in and trodden as hard as possible. The next trench is made a foot or 15 inches from the first one, and so on to the end.

Now if one of these cuttings fail it is by accident—as a rule, they all strike. They sometimes require treading in afresh after a sharp frost has heaved up the ground. "But does not a sharp frost kill them?" Oh no. Sharp frosts never hurt gardeners' Roses; it is only the fast-living Roses that sharp frosts can injure. I find my cuttings the wrong end uppermost sometimes after a sharp frost, they merely require putting back firmly before

the sun and air reach them to dry them too much. As for vigorous Rose plants of the Hybrid Perpetual class being killed by frost, I have never had an instance of such a thing in my practice, although I have known Oak trees receive injuries from frost from which they have not yet recovered.

The cuttings remain where they are first placed till the following November, when they are taken up carefully and potted, or they are planted either in their permanent quarters or in nursery ground 2 feet apart each way. In three years from the time of putting in the cuttings they form good-sized specimens. As my principal ambition is to obtain a large quantity of blooms, I do not object to large plants, and therefore do not prune so close as some do. I have plants now four years old which would be 4 or 5 feet through if tied out.

I ought to say that the standards grown in the clayey soil would not remove very well from it, and they are not intended for removal, but only to produce blooms for cutting. I consider standard Roses so ugly that I keep them out of sight as much as possible.—William Taylor.

GRAPE-FORCING—PRODUCTION OF LARGE BUNCHES.

We have been favoured with the following paper read by Mr. J. Hunter, Lambton Castle Gardens, at the Gardeners' Institute, Darlington, March 25th:—

"Gentlemen,—I have come before you to fulfil the promise I made to you when in the Mechanics' Institution that night so enjoyably spent in celebration of the first anniversary of the Gardeners' Institute—nobly founded by Edward Pease, Esq., for the benefit of all desirous of improving by it—you asked me to read a paper on the treatment the Vines received at my hands. The large Hamburgh bunch, being the one then in question, is included in the treatment of this house, to which I will only refer. I had the house put up in the spring of 1869; it occupied the old foundations so far as regards width, but was in length made nearly double by putting two into one. It may be interesting to some of you to know that this house stands on piles; and while I was making alterations I found after boreing that we stood 31 feet 9 inches from anything solid to work on; however, after getting a cement and brick bottom to my satisfaction, some 4 feet in depth, I resolved to have the borders made without further delay. Drainage on such a bottom as this must be efficient and thoroughly well carried out. In this case our front drain is built with brick, and pipes put inside, so that the top of the drain is a little below the cement bottom of border; at every 6 feet a line of 6-inch pipes crosses from front to back, and at every 4 feet from end to end of the house, the pipes thus forming a number of oblong squares 6 feet by 4 feet. These were filled up with brickbats to a foot in depth, and then with small stones and coarse gravel, after which it was turfed over with the grassy side of the sod downward. Soil suitable to make the border was the next important item. The park, or a portion of it, being drained previous to my coming to the gardens, I used turf which was put aside for gardening purposes, and cut fresh turf to make out with. To every six cartloads of soil I added one of lime *débris*, one of charcoal, one of burnt clay, three cwt. of broken bones, and a good dressing of clean cow manure, when the whole was turned over twice in the border, and in a few days the Vines were planted. Some of them were from one-year-old canes, and the others from eyes struck the same spring, the latter having a decided advantage at the end of the first year's growth, which advantage is maintained still. I found wireworm a most destructive enemy the first year. To check this all the surface of the border was smoothed over with the back of a spade, coated over with rape dust, laid over with thin boards, and covered up with 2 inches of old mushroom manure; this was turned over every alternate morning, then the wireworms were picked off the boards by hundreds. After this treatment the Vines carried their foliage well into December, when they were cut back to 6 feet from the bottom. I very soon after felt disposed to see what wireworms were left in the border, and also with a view of further assisting the Vines, I had an opening taken out at the back of the border and worked forward on them carefully with steel forks; every portion of the border was hand-picked and turned back until within 3 feet of the Vines; by this time we had a fine lot of roots laid bare. The soil was worked forward again, with the addition of a few more ingredients to the old, the roots being carefully laid in again. This has been done this and every year with one exception since planting, I doubt not with advantage to the Vines. At one place where I was under a noted Vine-grower I assisted in making over 100 yards in length of new Vine borders at various widths, and to my surprise, on removing the old Vines, which were considered A1 in their day, I found each had but a root or two to support them; they had taken up their abode in some quarter never made for them, as they passed out of the border without leaving a fibrous root in it. Imagine a gardener trying to assist the Vines by repeatedly watering and top-dressing such borders!

"I shall close my remarks, gentlemen, by giving the outlines of treatment the Vines had in this house. In the latter end of February the house was kept close previous to starting on March 1st, when syringing morning and evening, was well done, according to the weather. Fire heat was applied at 6 A.M., and taken off at noon. No fire heat was given at night unless compelled by frost. During the month the outside and inside borders were watered with 1680 gallons of tepid water, running on at the rate of seven gallons per minute through a fine rose. By the 15th no syringing was allowed overhead. April: for this month fire heat was turned off sooner in the day, weather permitting, but was applied immediately after shutting-up. On the 6th, so rapid was their progress that the shoots were pinched two leaves beyond the fruit and tied down. On the 13th the evaporating troughs were allowed to become dry, and fire heat used freely, front air put on at 8 P.M. and increased at 10 P.M. On the 20th they were in full flower; treatment the same, only the troughs becoming dry. 27th, all set, evaporating troughs refilled, applying front air more freely. Commenced thinning on the 1st of May; airing as last month. On the 13th watered the inside border with 3360 gallons of guano water at a temperature of 85°. After the 18th the temperature of this house was not allowed below 65°, when front air at nights was applied much more freely. On June the 15th the outside border was served with guano water the same as the inside, running at the rate of six gallons per minute, which lasted seven hours; quantity given 2520 gallons. Again, on the 29th, this house received 5040 gallons, and on July the 20th, 1680 gallons. All this was put on tepid, regular in temperature. Further than attending to the regular requirements, such as stopping, tying, thinning, &c., you have a correct statement of their treatment, except the temperatures, of which I hold an accurate account, but it would occupy too much space to enter into, as they were kept four times daily. I also experimented with the border of this house in the growing season of the Vines, the results of which I hope at another time to be able to bring before you, should they prove as suitable and satisfactory as they did last year.

"It may not be out of place, gentlemen, to raise the question, What are the advantageous points to Grape-growing in the county of Durham? Can it be the gases from the thousands of coke ovens that injure vegetation at distances off; or the immense volumes of smoke which we see continually hurled into the atmosphere, carrying with them the soot flakes which require a water-engine to play on your houses to admit daylight even dimly into them? Or the fumes from the chemical works, brought by a direct wind, sometimes overpowering the stomach of a bilious person in consequence of their nauseous stench? Some say wet localities have their advantages; here we have a dry one; in the Grape-growing season at Lambton Castle our rainfall did not exceed 10 inches. Some say soil; if so, why did not our predecessors, who used the same, do the same as us? In the way of experiment last year I had a small house of Vines planted, void of natural soil, except a small quantity which was used to surround the newly-planted Vines. The Vines have made roots from 8 to 10 feet in length, and turned out pretty good yearlings. This I only mention to show that Vines can be grown, whatever their staying powers may be, without turf or garden soil."

THE FLOWER GARDEN.—No. 1.

The cold and dreary weather of the winter that is now slowly passing away, while it has somewhat retarded many spring flowers, has injured none. The earliest bulbs have been in full beauty for some time, and the later kinds are putting forth leaf and blossom. Erica carnea, with its mass of bright pink flowers, is now at its best; Anemone coronaria now "robes the earth in beauty;" hardy Primroses are also in full bloom. The beds of Myosotis, Silene, Saponaria, and Violas which were planted about the end of last October are in excellent condition, and will form lovely masses of various

shades of white, blue, purple, pink, and yellow from April till June, when the summer bedders now in course of preparation will replace them.

It is a singular fact, that while the artistic arrangement of summer beds has met with numerous opponents, no one has ever been found to speak against spring gardening. The loveliness of the flowers, blending so softly and harmoniously with the fresh greenery of the foliage, are so impressive, so bright and seasonable, as to command universal admiration and approval. Nor is the display of vernal beauty confined to the gardens of the rich; it is open to all, the best spring flowers being raised from seed and cultivated entirely in the open air, ordinary care and painstaking, combined with timely culture, being all that is necessary to secure an ample stock of plants.

Taken apart from its intrinsic beauty, spring gardening enables one to be more deliberate than of yore in the work of providing the necessary supply of summer plants. The old high-pressure system of propagating the stock so as to be in readiness to plant the bare beds as early in May as possible has become obsolete, for the simple reason that the spring flowers continue in full beauty throughout that month. There is, therefore, ample time for the propagation of many plants for the coming summer display. Take, for example, that best of all dark crimson-foliaged bedders, Coleus Verschaffelti; one large plant or half a dozen small plants placed in a lively temperature will afford thousands of cuttings in a few weeks, every joint or eye rooting freely in saucers of sand and water. Then there are those unique bedders, the Alternantheras, most lovely in the brightness and variety of their leaf tints. A few strong plants plunged to the pot's rim in a hotbed yield cuttings freely, and which also root readily in pure sand and water. The dark-leaved Iresines, too, are propagated with equal facility. I very well remember how, when Iresine Herbstii was first introduced, each portion of stem with a joint was split asunder so as to obtain a plant from every eye. I. Lindeni too was seized upon with avidity, and was very popular for a time, but neither of them have continued to hold the prominent position at first assigned to them, for the simple reason that they are undoubtedly dull-looking and tame. In the Coleus we have both depth and richness of colour; in the Alternantheras brightness, beauty, and most charming variety; but these desirable properties are all wanting in the Iresines.

Some of the yellow-leaved plants answer best if raised now. A shilling packet of Golden Pyrethrum seed will afford some thousands of plants. Stellaria graminea aurea is easily propagated by cuttings, which grow with surprising rapidity, and emit roots from every joint. Vinca major elegantissima is also readily propagated from cuttings at this season of the year. Coprosma Baueriana variegata is a more difficult plant to increase, the cuttings rooting slowly but surely if the pots are plunged to the rim in a brisk hotbed. It is sometimes recommended to propagate this plant by layers in preference to cuttings—a tedious and unnecessary process, as the cuttings are to be depended upon. A strong batch of both yellow and white variegated Geraniums raised from cuttings now make compact little plants for edgings or second rows. Mesembryanthemum cordifolium must not be overlooked here, it is so easily cultivated and so useful withal as to merit a place in every garden. It may be raised from seed; cuttings, however, root so freely, and may be taken in such abundance from a few plants, that they are altogether preferable to seedlings. Its chief points of excellence are found in the peculiar softness of its foliage, in which pale green and yellow are agreeably blended, and in its recumbent, dense, and spreading growth requiring very little attention after it is once established.

All the grey-leaved plants may now be propagated with tolerable ease and expedition from cuttings, Santolina, Leucophyton, Cerastium, Achillea, Gnaphalium, Centaurea, and Cineraria maritima, all rooting freely in a lively moist temperature. The Centaureas and Cinerarias may be raised from seed, but the seedlings grow so slowly that they are of very little use till the second year. Both species prove hardy in a dry, elevated, and open situation, forming handsome specimens if planted singly. The Cineraria with its silvery stems and bright grey deeply serrated foliage possessing a brightness and beauty that is as remarkable under favourable circumstances in winter as in summer.

The exquisite effect of Tagetes signata pumila under skilful management, so well exemplified at the Crystal Palace last year, will probably induce many persons to assign it a prominent position in more than one flower bed for the coming season. I would not advise anyone to attempt its culture who cannot afford it almost daily attention, for it grows so freely and flowers so persistently throughout the season, that a few days' neglect would lead to the production of much wild growth and of many flowers which ought always to be removed in the bud. If the seed is sown in gentle heat now, the plants will be in a suitable condition by the time they are required for the beds.

Lobelias, Violas, Tropæolums, and Ageratums are all best increased from cuttings. Violas raised now would, of course, be somewhat late, but they would be highly ornamental in autumn.—Edward Luckhurst.

ROYAL HORTICULTURAL SOCIETY.

April 21st.

This, the second spring Exhibition, was held under the auspices of a pleasant summer-like day. Even the most tender plants could be moved with safety, and their admirers could enjoy them as flowers ought to be enjoyed, in leisure and comfort—if the plants had come. The collections were arranged in the western conservatory arcade. More than half the classes were empty, and we cannot describe the Exhibition other than an ordinary one, although the Rhododendrons were massive, the Orchids interesting, the hardy flowers as attractive as any class in the Exhibition, and the cut blooms of Maréchal Niel Rose simply splendid.

The first class in the schedule was for twelve forced Rhododendrons (open). The only collection was from H. Lane and Son, Great Berkhampstead, with well-bloomed plants of Nero; Blandyanum, a fine plant; Limbatum; Queen of the West, very effective; Auguste Van Geert, with immense trusses of blooms; Etandard des Flandres; Towardianum; Fatuosum flore-pleno, very lively; Minnie, an attractive light variety; Sir Isaac Newton, a rich dark; Imperatrice, and Lord John Russell. All the plants were exceedingly well bloomed, and were healthy and fresh. In the corresponding class for amateurs there was no entry.

In the Orchid class for nurserymen Mr. B. S. Williams was the only exhibitor. His collection comprised a good plant of Dendrobium nobile, Cypripedium villosum with fourteen flowers, Odontoglossum luteo-purpureum with two fine spikes of a dozen blooms each, Camarotis purpurea, Masdevallia Lindeni, and Odontoglossum phalænopsis. The amateurs' class was empty.

In the Cineraria classes for nine distinct varieties (nurserymen), Messrs. Dobson & Son, Isleworth, had large but rather loose plants of Wonderful, Premier, Snowflake, Hamlet, Duke of Cambridge, Ensign, Lady Hamilton, Beauty, Andromeda, and a miserable semi-double variety. In the amateurs' class for this plant there was no competition.

Hardy spring flowers in pots. These were very effective, the first prize for eighteen varieties being secured by Mr. R. Parker, Exotic Nursery, Tooting, with bright examples of Doronicum cordifolium, D. austriacum, Cardamine trifolia, Tritelia uniflora and T. uniflora lilacina, Primula elatior Early Admirable very rich, Scilla italica, Spiræa japonica, Saxifraga media, Orobus vernus, Iberia linifolia, Muscari racemosum, Dielytra spectabilis and D. spectabilis alba, Orobus cyanus, Primula elatior Golden Plover, Pulmonaria siberica and Ranunculus amplexicaulis. Second honours were taken by Mr. Dean with smaller but not less attractive plants, among which bedding Pansy White Swan, Viola Royal Blue, Lithospermum prostratum, Primula cortusoides in variety, Polyanthus Black Knight, White Daisies, and Myosotis, were the most effective. This was a compact, well-grown, and interesting group.

The Auricula classes were empty save that for twelve Alpines. Messrs. Dobson & Sons staged plants of no special merit.

In the miscellaneous contributions a small but interesting collection of double, single, and fancy Polyanthuses were sent by Mr. Dean. Of the single varieties Viceroy (primrose), and The Bride (white), are evidently good bedders, and a large laced variety Hussar is effective. Some of the double varieties were also exceedingly rich.

Mr. Williams exhibited an attractive group of plants, comprising choice Palms, Pandanus Veitchii, Anthurium Scherzerianum, a nice plant of the Sweet Toxicophlæa spectabile, Orchids, &c.

A batch of double Cinerarias were sent by Messrs. E. G. Henderson & Son, two or three of which were really double, the remainder being more or less successful attempts to break from the single form. The same firm also sent some single seedlings containing good flowers.

The ninety-six cut blooms of Maréchal Niel Rose from Mr. Walker, nurseryman, Thame, Oxon, deserved a medal for their great excellence. Nothing in the Exhibition was better in quality than these fine, fresh, rich blooms.

The Society's Gardens came to the rescue with gay collections of plants, in which the pots of Solomon's Seal showed to ad-

vantage. The Azaleas, Acacias, Narcissus, &c., were well-bloomed hardy plants.

Withholding the prizes for last year's shows and diminishing the amounts this year is having its natural effect on exhibitors, and restricting the scope and interest of the exhibitions.

Fruit was limited to the following contributions:—For two bunches of Black Grapes the first prize was awarded to Mr. W. Bones, gardener to D. McIntosh, Esq., Havering Road, Romford, for compact and well-coloured bunches of Black Hamburgh, the second honours going to Mr. Ridout, gardener to W. S. Brown, Esq., Woodhatch Lodge, Reigate, for Alicantes, fine in berry and colour, but losing freshness. Two bunches of White Grapes were represented by small bunches of Golden Hamburghs from Mr. Bones, who exhibited also a basket of highly-coloured Tomatoes Earley's Defiance, which were worthy of recognition. Cucumbers were repreaented by a good brace of Tender and True from Mr. J. Lane, gardener to Major-General Fytche, Pyrgo Park, Romford; and a brace of Marquis of Lorne from Mr. Rapley, gardener to R. Hudson, Esq., Clapham Common, which took first and second prizes respectively.

Fruit Committee.—Henry Webb, Esq., in the chair. Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., Leonard's Lee, Horeham, sent six dishes of Apples and two of Pears, which were very well kept, and to which a letter of thanks was awarded. William Terry, Esq., Peterborough House, Parson's Green, sent two large clusters of the fruit of Vanilla, perfectly ripe and admirably grown. The Committee unanimously awarded a cultural commendation. Mr. John Monro exhibited a basket of Keens' Seedling Strawberries, grown from cuttings. Mr. Monro also sent six fruit of his Cucumber Duke of Edinburgh, also three bunches of Grapes, Foster's Seedling, Buckland Sweetwater, and Madresfield Court. These fruit are from pot Vines taken from the open ground on the 4th January, 1875, into 80° of heat at once, where they have been kept ever since. There were fifteen bunches on the Foster's Seedling, seventeen on the Madresfield Court, and eight bunches on Buckland Sweetwater. A letter of thanks was awarded for the collection. Mr. Bond, gardener to G. A. Smith, Esq., The Beeches, Weybridge, Surrey, sent two Vines in pots of Foster's Seedling, fifteen months from the eye. They were awarded a cultural commendation. Messrs. Lee of Hammersmith sent a dish of Bess Pool Apple. Rev. George Kemp, The Vine, Sevenoaks, sent a dish of Sturmer Pippin, very well kept, and of excellent flavour.

Floral Committee.—R. B. Postans, Esq., in the chair. A small but charming group of Orchids was contributed by Messrs. James Veitch & Sons. Phalænopsis Luddemanniana ochracea, from the Phillipine Islands, is a distinct waxy gem of a curious admixture of colour of green, pink, and scarlet. Cattleya elegans alba had a spike of four beautiful blooms. Saccolabium ampullaceum had half a dozen glowing spikes. Phalænopsis amabilis, and P. Schilleriana, and Odontoglossums in variety, were in excellent order. The same firm also exhibited a very distinct Dracæna, named hybrida, for which a first-class certificate was awarded.

Mr. Kinghorn, of Sheen Nursery, Richmond, exhibited a plant of his new and curious Fuchsia procumbens. It is very singular and pretty, as much like a Tropæolum as a Fuchsia. It is undoubtedly interesting by its distinctness. Mr. B. S. Williams sent a new Echeveria, E. de Smetiana, with very silvery foliage; also plants of Franciscea magnifica with very fine flowers. Mr. Z. Stevens, Trentham Gardens, sent a splendid plant of Cœlogyne cristata (lemoniana), and received a vote of thanks.

Mr. Bull sent Tillandsia musaica, Dracænas, and Arguloa Turneri. Mr. Bond, gardener to G. A. Smith, Esq., sent good plants of the Orchids Brassia maculata and Oncidium altissimum.

Mr. H. Bennett, Stapleford, Salisbury, had a first-class certificate for twelve pot plants of the new and excellent Rose Capt. Christy. He had also beautiful cut blooms of Duchess of Edinburgh, Madame Caroline Kuster a soft yellow, Hippolyte Jamain, and Mdlle. Marie Cointet. Mr. W. Paul exhibited a good dark Rose Villaret de Joyeuse, and a sweet-scented light variety Amelia Haste.

Mr. Eckford again sent some of his fine laced Polyanthus; they are very distinct and bright. Mr. R. Dean exhibited a double white quilled Daisy of fine form and substance, which received a first-class certificate. A collection of fifty varieties of Narcissus was sent by Rudolph Barr, Esq., Tooting. Their variation in form and colour, their brightness and perfume, rendered them very interesting. They merited the vote of thanks which was awarded them.

THE LEAMINGTON BROCCOLI.

The seed of this new sort of Broccoli was distributed with the prestige of a first-class certificate from the Royal Horticultural Society, thus raising hopes and expectations that it would prove not only different to, but a decided improvement upon existing kinds. The earliest plants of it here are from seed sown March 18th, 1874, and they are now affording a fine supply of what I consider to be the best heads of Broccoli I have ever sent to table.

In form the heads may be compared to a cone with the sides slightly bulging out, some tapering more to a point than others; all are extremely compact, white, and delicate, and are so closely enveloped—that is to say, protected by the leaves, that some care and pains are necessary in cutting them away in order to find the treasure which they guard so closely and so well.

Thus, then, the expectations of a "good thing" raised by the certificate are in this, as in most other instances, fully realised. I lay some stress upon this, because of late it has become very much the fashion to decry the Royal Horticultural Society, and to question its utility. Now, I for one can undertake to say that if the Leamington Broccoli had been offered for sale without having gained the high award which its great excellence so justly merits, I should not have been tempted to purchase.—Edward Luckhurst.

FLOWER-BEDS IN ASWARBY PARK GARDENS.

The gardening at Aswarby Park, the seat of Sir Thomas Whichcote, Bart., near Folkingham in Lincolnshire, is well

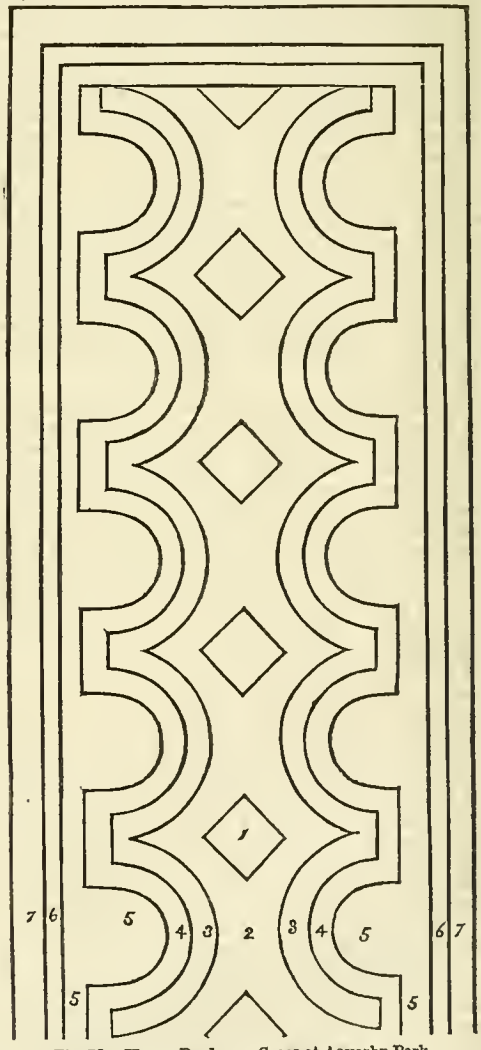

Fig. 76.—Flower Border on Grass at Aswarby Park.

Border No. 2, 80 Feet by 12.

1. Centaurea candidissima.
2. Coleus Verschaffeltii.
3. Christine Geranium (pink).
4. Miss Kingston Geranium (silver variegated, with the flowers picked off).
5. Lobelia pumila flore-pleno (one mass of bloom).
6. Golden Feather.
7. Echeveria glauca metallica.

known and admired. Mr. R. Nisbet, the head gardener, has most obligingly enabled us to give details of some of the flower arrangements.

It only needs reference to the plants used and their mode of disposition, to appreciate how effective is Mr. Nisbet's mode of planting. The flatness of the large bed is artistically broken by the use of Dracænas, Aralias, and Acacias. The border planting is an example of brightness without glare.

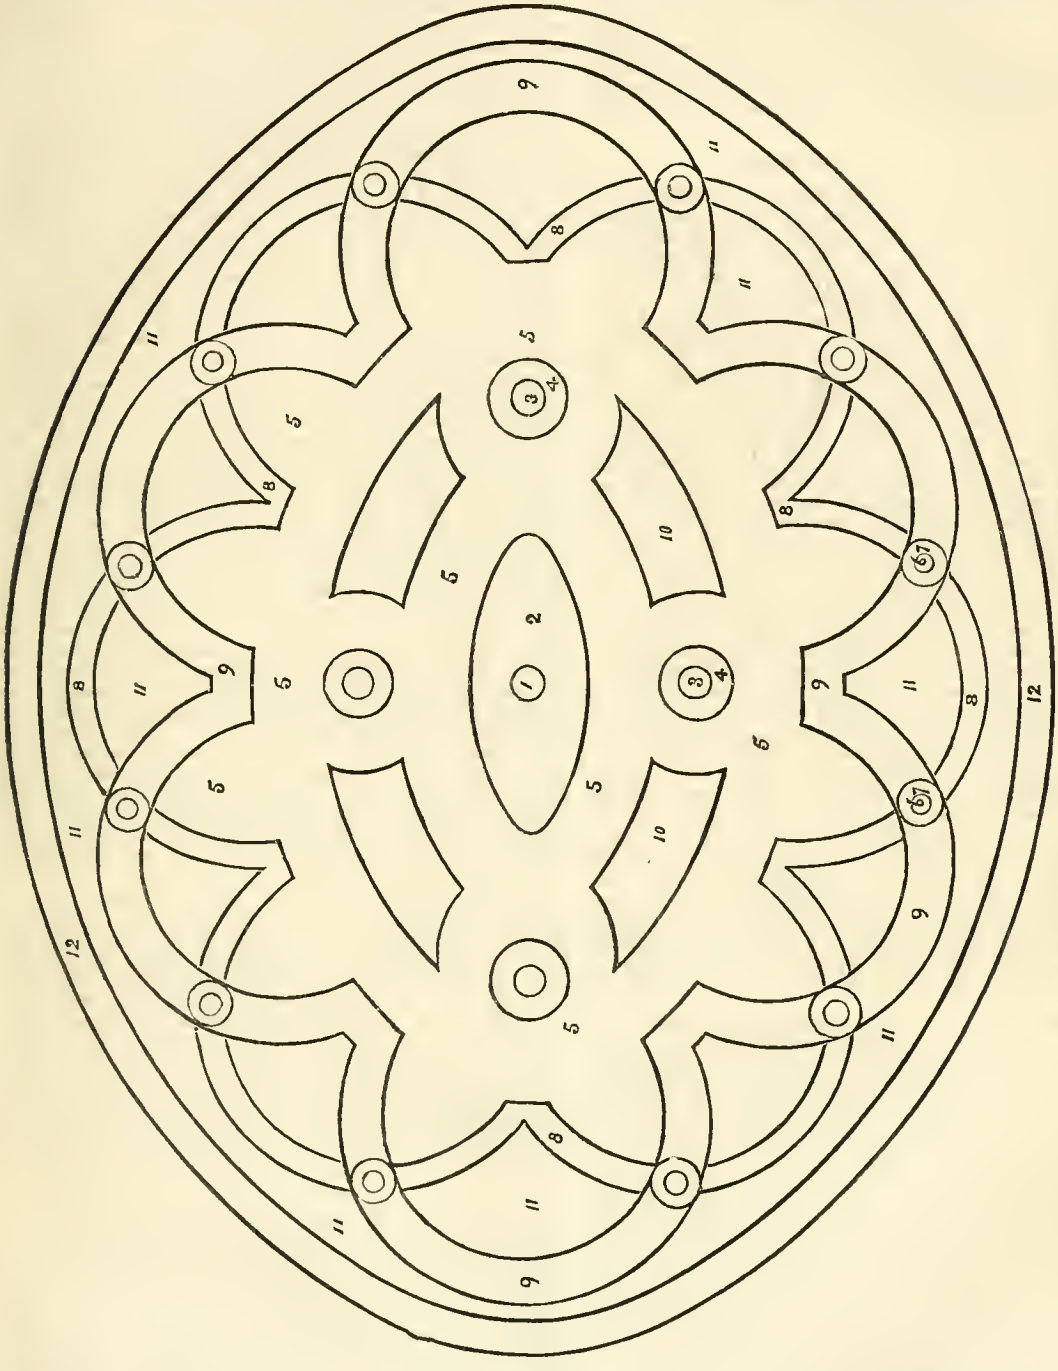

Fig. 77.—Flower bed on grass and arrangement of the planting at Aswarby Park.

Bed No. 1, 50 Feet by 36.

1. Dracæna australis.
2. Calceolaria Kayi, yellow.
3. Aralia papyrifera.
4. Verbena venosa.
5. Alyssum saxatile variegata.
6. Acacia lophantha (seedling plants).
7. Iresine Lindeni.
8. Viola Perfection.
9. Harry Hieover Geranium.
10. Vesuvius Geranium.
11. Mesembryanthemum cordifolium variegatum.
12. Edging of Ivy.

The garden is always much and deservedly admired by visitors. It is unquestionably under able supervision.

To save space we have only had half the border engraved, as the other half is merely a repetition. Another border exactly similar balances it.

STANSTEAD PARK CABBAGE LETTUCE.

I should like to say a word in favour of that excellent hardy winter Lettuce Stanstead Park Eclipse, for it has often stood me in good stead when all others have failed. At the present time I should have been quite at a loss without it for early spring salads. By early salads I mean those gathered entirely from the open borders, and which are always required at this season of the year to follow the winter frame salads.

The Stanstead Lettuce is a strong-growing kind, almost as large as the Neapolitan, and so robust that it not only withstands the severity of such a winter as the past perfectly well, but grows and "hearts" so quickly in spring that it is fit for use long before the other varieties. It is not a desirable sort

for frames, its large size causing it to occupy, and in reality to waste, much valuable space; all the large spreading outer leaves being worthless for salads.

The crop that is now being used is from seed sown August the 1st, and transplanted along the foot of a Peach wall facing the south on September the 12th. All the Year Round Cabbage Lettuce and Walker's Sugarloaf Cos were sown and transplanted to a similar position on the same dates. They will form a capital succession to the Stanstead, and will be followed in turn by Bath Cos and Kingsholme Cos, which had been sown a fortnight later.—Edward Luckhurst.

ROSE TREES AND FROST.

I have read Mr. Peach's communication, and fear that on this occasion we must still be content to differ. I am gratified to hear that, as a rule, our opinions agree. For my own part I have to thank him for many interesting communications, and have usually found that my own experience coincides with his both in the matter of Rose and Strawberry culture.

Mr. Peach admits that old wood may be enfeebled by the growth of young wood from the base, but thinks that this will not account for the frost killing old wood still strong and vigorous. One does not, of course, dispute the fact that frosts are occasionally severe enough to cut down all Roses to the ground whether strong or weak. This is not the point at issue. What we want to discover is, How it is that the old wood is, as a rule, the first to succumb to frost, while the strong green shoots thrown-up from the base hold out to the last. What makes the difference? Mr. Peach introduces the Delphinium formosum as an instance of a plant, the young growth of which will stand a very low temperature in spring, but the matured growth of which is cut down by a slight frost in autumn. It is hardly safe, however, to compare the Rose with other plants, or we shall be lost in a maze of difficulties over the vagaries of frost and the surprising difference in its effect on various forms of vegetation. Why, for instance, should 1° or 2° of frost suffice to destroy the Heliotrope, while the Calceolaria by its side endures without injury some 8° or 10°? I am not aware that there is any such vast difference in the structures of the two plants to account for this difference of constitution. The frozen sap would have an equal chance of expansion in each, and yet one dies and the other survives. It would be useless to multiply instances of this sort. Every gardener knows that the appearance and structure of his plant is but a very slight guide as to the climate it is fitted for; and does this not plainly prove that, although the action of frost is to a certain extent mechanical, its effects differ, not so much from differences in the structure of plants as because the Creator has given to each plant a constitution which fits it to occupy the position in which it is placed, and renders it capable of enduring without injury the various extremes of temperature to which it is usually exposed in its native home?

Now, in the case of Roses, when one finds that certain plants and certain portions of plants which ought to be as hardy as the rest which survive, nevertheless succumb to frost, I believe we must look further than for some mere difference in the structure of the wood or the mechanical action of the frost. Observation tells me that the more vigorous the plants are the better they are able to withstand a low temperature; that when a number of plants are destroyed by frost it is usually the youngest which survive; that when portions only of plants are destroyed it is usually the young strong wood that escapes; that standards, owing to an artificial system of culture, are, as a rule, less hardy than dwarfs, and in case of severe frost succumb first. Mr. Peach says that in 1860 he lost ninety-eight standards out of one hundred plants which, he adds, were pruned in the very manner I advocated in my last; but surely Mr. Peach does not suppose that I was referring to any but dwarf Roses when I pointed out the two methods of cultivation whereby the wood might be kept in a vigorous and frost-proof condition?

The loss of so many standards confirms me in my opinion that they died from the effect of the low temperature acting on a weakened constitution, which rendered them less hardy than the same varieties on dwarf stocks. If it were owing to any peculiarity in the structure of the wood, why were standards only killed? Surely there must have been some young shoots among them as well as old, and surely the structure of the wood cannot differ so materially on standard and dwarf stocks. Now, as I pointed out in my last, if one desires to keep either a plant or a shoot strong and healthy, the circulation of the sap must be fully maintained during the season of active growth throughout the whole of that plant or shoot. Anything which tends to impede, obstruct, or divert this circulation tends also to lower the constitutional vigour of that portion which loses its necessary supply of sap. The tendency of most Roses is to renew their wood periodically from the base, and thus to maintain their life and vigour—the old wood gradually dying away, and the young shoots taking its place. The hedgerow Briar is no exception to this general rule, as anyone may see for themselves who chooses to take a stroll down some country lane where Briars abound. In the autumn he will see shoots from 6 to 10 feet long standing up above the hedgerows as thick as a man's thumb, most of which spring from the base of the old wood. Does the frost, I wonder, ever kill any of them as long as they are allowed to manage themselves in their own way? But they are torn violently from their homes, decapitated, mutilated at their heels, planted without roots in a dried-up condition, and when they do manage to live are put to the torture in various ways during their season of active growth. The stocks try to make roots, and throw out a multitude of side shoots to forward their endeavours. All but three or four near the top are removed; the consequence is rooting is checked, and feeling a trifle ill they throw-up suckers, which are at once pulled-up. At budding time two or three buds are inserted of a Rose probably which has about a tenth part of the natural vigour of the Briar. The next season, after enduring still further torture, the buds start. At the same time the poor Briar makes another effort to prolong its existence in the shape of more side shoots and a few more suckers, all of which are ruthlessly removed, or they would rob the bud. Well, the bud grows and forms its head, and a grand head it is; so unnaturally small compared with its sturdy trunk that it is utterly unable to draw up a tenth part of the sap which that trunk requires. It can supply its own little wants, it is true; but what can its half-dozen leaves do for the Briar in return? Why, it can scarcely breathe. The weaker the variety budded on the stock the more suckers it will now try and throw up, and the sooner, if those efforts are defeated by the careful rosarian, will it languish and die. Mr. Peach knows as well as I that some sorts of Roses which are weak growers will only drag out a brief existence of one or two seasons on the standard Briar do what one will, and that a good sharp frost will kill scores of these weaklings. People wonder how it is that so many of their plants die. They think it is the frost, or the drought, or the green fly; anything, in short, but the real reason—that they are cultivated in opposition to Nature.

But, cannot a standard Briar be kept healthy? Yes, by budding it with a very strong-growing variety. I have just cut down an old standard Gloire de Dijon which must have been nearly fifteen years old. It had shoots from 10 to 20 feet long. The stock increased in thickness every year, and never threw up suckers. Why? Because the large head supplied all its wants, and kept up the circulation of the sap to and from the roots, for one is quite as necessary as the other. Bud a Briar standard with Charles Lawson or La Ville de St. Denis—grow it well to form a large head, and it will live almost as long as you like, and defy all but the severest frost. Why did the frost kill Mr. Peach's Briars? Answer—because there was not one of them truly healthy. If anyone can prove that I am wrong I am ready to stand corrected.—R. W. Beachey.

ORCHIDS AT MESSRS. VEITCH'S NURSERY.

As an addition to the excellent report which appeared in the Journal (page 158), a few remarks on some of the Orchids which have subsequently flowered may be interesting to some readers. Orchids are being more extensively cultivated than formerly, and many persons take to this class of flowers as a hobby who know but little of gardening generally; they give much personal attention to their pets, and in time become intimately acquainted with their requirements. In some instances gentlemen begin collections of Orchids and engage a gardener who knows but little more of the business than they do themselves, and gardener and master acquire a practical knowledge of the plants together very often by paying well for it. Leaving out the mistakes made in culture, there is one grievous error very often made, and that is buying collections of cheap plants. I think it was Thackeray who said in one of his novels, "Some persons buy their wine cheap and good; I buy mine dear and good." It is the same with Orchids: you

cannot buy them cheap and good, and, what is more, the dearest plants are the cheapest in the end.

After a person has become acquainted with the merits and rarity of the different species, he can purchase in any market, but until this knowledge is obtained the best way is to trust to some firm who make a speciality of them; but do not purchase collections of any species at a few shillings per dozen. One ought to have considerable knowledge of the culture of an Orchid before he ventures to pay £50 for a plant. Indeed as much as from fifty to a hundred guineas are sometimes given for good healthy specimens of some of the more rare species.

What are designated cool Orchids are now becoming very popular, and amongst them a large proportion of the numerous species of Odontoglossum are amenable to this treatment. The latest addition to this class is O. Warscewiczii. The habit of the plant much resembles the beautiful O. vexillarium, and, like it, is not only very scarce in its native habitat, but it is also very difficult to bring plants over alive, so that it is not likely ever to become common. The flowers are not so striking in appearance as the allied species; they are white, with pale yellow at the base of the labellum; but as the plants are only recently imported it would not be fair to pass a final opinion upon them.

One thing I would say as a warning to cultivators—Do not grow this species, nor O. Roezlii, O. vexillarium, nor even O. citrosmum in the coolest house with O. crispum, O. triumphans, and other allied species, as there is great risk of losing them in the winter. I heard a gentleman say that he had lost all his O. Roezlii by keeping them too cool, and only saved O. vexillarium by placing the plants in a house with a higher temperature. I was informed at Messrs. Veitch's that O. Roezlii succeeded remarkably well in a minimum winter temperature of 60° or 65°. Some plants of it at Loxford Hall grown in a winter temperature of 45° showed evident signs of being uncomfortable, and improved when removed to a warmer house. The plants that suffered most were those that had not ripened their young growth.

In your report O. crispum (Alexandræ) and O. triumphans are mentioned. Not only are they very distinct from each other, but they are the very cream of the cool-house species, and the flowers will remain in full beauty for three months or more during the winter season. O. Andersonianum is a very fine species, but little known; it is no doubt a natural hybrid between O. crispum and O. odoratum. I had a plant of it amongst a lot of plants presumed to be O. crispum. Some of the varieties are very near O. odoratum and merely show the cross, others are but little removed from O. crispum. An important addition has also been made to the Masdevallias: it was discovered and sent home by the Messrs. Veitch's collector Mr. Davis, after whom it has been named M. Davisi. The growths somewhat resemble those of M. Veitchii, and the flowers are said to be like those of M. ignea in colour. Whether superior to that variety remains to be proved. It had the appearance of being a free-growing species.

Passing to the houses containing those from warmer latitudes it must be admitted that, beautiful as are many of the species grown in cool houses, they must give place to the others. Can any flower be of a more delicate transparent white than the magnificent waxy blossoms of Angræcum sesquipedale? but it is a Madagascar plant and luxuriates in a very high temperature. Mr. Darwin has stated that the moth or butterfly that could suck the honey out of the extremity of the long tail-like appendage attached to the flowers must be furnished with a proboscis 18 inches in length. Then we have the glorious Dendrobiums from India. D. lasioglossum was in flower. These are very small but very beautiful. The sepals and petals are white, and the labellum streaked with purple. In striking contrast to it were some beautiful specimens of D. primulinum giganteum. This is a magnificent variety of the species; the spikes are pendulous, and show off to advantage the splendid blush-white flowers; the large lip is stained and streaked with delicate purple. No collection should be without this fine plant. D. crassinode had two young growths with twenty flowers, white with an orange blotch at the base of the lip. A fine plant of the extremely rare D. Wardianum will soon be in flower. The growths were very strong, and thirty-five unexpanded flowers were counted on three spikes: the strongest spike had fifteen flowers. Dendrobium speciosum was very fine. The flowers are creamy white, and though not very striking in appearance individually, show up well on the plant.

Vanda Cathcarti was making strong growth and shows three spikes. Vanda Parishii, which has only flowered once or twice in England, is making very vigorous growth. The plant shows two very strong spikes. The flowers are not very striking; they lack the bright clear colour of V. suavis and some of the V. tricolora, but they are sweetly scented. V. cœrulescens from Burmah is also in flower. The small plant is furnished with an elegant spike of the richest blue flowers I have yet seen in Orchids. This is not an exhibition variety, but it is "a gem of purest ray serene" notwithstanding.

There is also at present in flower a plant of a natural hybrid Phalænopsis. A quantity of imported plants of what was presumed to be a natural hybrid was sold at the rooms of Mr. J. C. Stevens last year. They were named P. intermedia. The cross was stated to be between P. amabilis and P. Schilleriana. They have all, I believe, turned out to be P. amabilis. Of the species in flower at the Exotic Nursery there can be no manner of doubt, as the plant has the marked characteristics of both parents, P. Schilleriana and P. rosea: it has been named P. Veitchii. Many attempts have been made in this country to raise seedling Phalænopsis, but all such have proved abortive. Seedpods can easily be obtained with millions of good seeds, and these have also been known to vegetate, but flowering plants have never been obtained.—J. Douglas.

NEW PLATYCERIUMS.

There may be seen in our nurseries at the present time two Platyceriums (Stag's-horn Ferns) of great interest and beauty—one the rare *P. Wallichii*, now in first-rate condition at Mr. B. S. Williams's, Upper Holloway nursery; the other *P. Willinckii*, a magnificent new species in the possession of Messrs. Veitch & Sons of Chelsea. The amusing similarity of the names (pronounced, of course, Wallick-ey-i and Willinck-ey-i) has induced one of our correspondents to send us the following lines:—

THE RIVAL PLATYCERIUMS.

Said Chelsea, "Ma'am, now have you seen my best of all the genus?—
My Platycerium—lovely mum; and just a word between us,
It christened is *Willinckii*,* none ever saw its equal!"
Then Holloway, she tossed her head, and said—as in the sequel,

"I don't know nothing 'bout your brat, but I've a lovely treasure,
A Platycerium (next to new) whose beauty has no measure.
Mine has been called *Wallichii*; yours must be an impostor,
Some wretched Fern from Dutchman's land, bought perhaps of a coster."

They can't agree about their names, no matter how they try,
Wallich, Willinck, with vowels two, which makes them all my "i."
In such a case what can be done? Pray how is it to be, sir?
With Pomp and Cæsar much alike, especially poor Cæsar.

BEDDING GERANIUMS, AND AN EASY WAY TO PROMOTE THEIR GROWTH.

Your correspondent Mr. Osborne has pointed out a very useful and convenient way of preparing the bedding Geranium for planting-out. As a modification of the plan has been adopted here, and as it may not be known to all to whom it may be useful, I append the mode in which we have been in the habit of treating them more or less extensively for nearly twenty years. I believe it was adopted before that time by others with some little variation, but in our case the mode from the first was much as we practise it now. Instead of the term "sodding," as Mr. Osborne has it, we have been in the habit of calling it "mossing," as we use moss more than anything else. I almost envy Mr. Osborne using the home-grown tying material, New Zealand Flax, but not on that account alone, but on the supposition of his having so many other plants outdoors that we are compelled to keep under glass; but as a substitute for the Russian mat, I think we have more than once managed to have some very good home-grown matting from Lime trees that have been cut down. In a general way, however, the foreign article has been put into requisition, and with care in the selection the cost of the material need not be a serious obstacle.

Our mode of operation is this:—The Geraniums are such as have stood the winter in shallow boxes, which with us are all of one size—viz., 2 feet long by a trifle over, 1 foot wide, and for Geranium cuttings are 3 inches deep, while for stowing away old plants they are the same size in length and breadth, but about double the depth; but as it is mostly the former that we are now alluding to, I may add that in a usual way about seventy cuttings are put into such a box in September, and allowing for losses during the winter, if the average of strong-growing plants exceed forty when they are potted-off or

* Named after M. Willinck, a Dutchman.

are mossed, they have kept pretty well. We do not commence the mossing process so early as Mr. Osborne from not having frame accommodation in March, and also from the wish we have of each plant furnishing one or more cuttings before it is disturbed. About the 10th of April, and from that time up to nearly the end of the month, is the time we have found most convenient, as our means of shelter is very homely. I may say that some time before we begin some boys are sent into the woods where moss abounds and a large quantity is obtained, which on being brought home is looked over and sticks, especially thorny ones, are picked out, and a tub being filled with it and stamped down, boiling water is poured over it so as to saturate the moss. This scalding not only destroys all insect and animal life that may be lurking inside, but destroys vegetable life as well, and also the seeds of noxious weeds that may be troublesome hereafter. This done and whether the moss be allowed to dry or not it is ready for use. A quantity of soil being handy on the potting-bench, the boxes of Geranium plants are brought out and are shaken-out with as little injury to their roots as possible, and the operator placing a piece of moss flatways on his left hand adds a little soil in the centre of it, then lays on the cutting with its roots on the soil, putting at the same time a little more soil over that, then folds-up the moss all round the whole, and wraps round it a piece of matting, which for convenience is prepared into lengths to go about three times round the moss. When completed it resembles a small plant growing in a little mossy bundle of the size of a large goose egg, the moss reaching to the lower leaves. This work, as Mr. Osborne justly remarks, is suitable for a wet day. Boys with a little experience often excel their seniors in quickness of mossing, and a great many Geraniums may be thus disposed of in a day.

The next question is, What to do with them? No doubt a frame placed on a properly made-up hotbed would be best, but the usual frames required for forcing are generally always in use at this time, that some other makeshift has to be adopted. In our case we have some old spare lights, and a rough frame is made by nailing four 9-inch wide boards together the size of about three of the lights, which is about 10 feet by 6. These boxes with care will last several years, and are useful in many ways. I may also add that we generally have plenty of leaves, which with a little dung added, form a very suitable hotbed, which, however, is only very slight, and the bed is usually made higher on one side than the other to allow the rain to run off the lights; the frame is put on, and a little soil is put in, the tied-up plants are packed in rows almost touching each other, and very often partly slanting to keep their heads below the top of the boards, a little soil being pressed against them as the work proceeds. The frame is speedily filled, and if the moss has been dry when used a little watering is given, but if otherwise, very little is wanted while they are there, and the lights which are put on at once may, nevertheless, be partly removed on fine days, and entirely so before planting-out time, when the plants will be found to have formed a set of bearded roots projecting through the mossy ball on all sides, and as we usually put a good proportion of leaf soil into the compost they are grown in, much of it adheres to the roots and travels with them to their final quarters. We have thought the roots of such plants are in a better condition for transplanting than the pot-bound plants often met with, but on this head I have some misgivings, and am not certain but the porous material around the ball of the plants allows a very dry season more chance to do mischief than when all is more firm and solid. Although I have had many years' experience with mossed plants on as extensive a scale as most people, I will not undertake to give a positive opinion on that head, but it has many other advantages in its favour, which it may not be out of place to mention here.

First of all it will be generally admitted that the months of April and May are exceedingly busy months in all gardens. Anything that tends to diminish labour at this season is a boon, and not the least important matter is watering, which everything in pots require at this season; and although the rose watering pot may be dexterously used so as to water a good many at one swing, whether they all want it or not, the repetition of the process consumes time, besides which water is not always so plentiful as could be wished. Now, plants treated as has been shown require very little water indeed; nay, I am not sure but some frames we have had were never indulged with any given in an artificial way.

Secondly. When planting time arrives there is a vast deal less carriage in removing a thousand moss-tied-up plants than the same number in pots, as the former can be heaped-up on the hand-barrow or basket without much damage, and be only a fraction of the weight of the potted plants, besides which there are no pots to return to the store, and all the extra trouble of washing and preparing them for the purpose is avoided. Many other reasons might be urged in its favour, which can be left to the general reader to consider for himself in accordance with his individual means of meeting either the tying-up or potting system as his means may allow; at the same time due allowance ought to be made for the cost of pots if they be decided upon, for notwithstanding all care a certain breakage and loss will occur whenever they are used.

With regard to the relative time of the potting or tying-up, there is no question but the first is the quickest, but the stowing away in a becoming manner makes the two about equal, for as a piece job men have offered to do the tying-up at 6*d.* per hundred, which is not much, but the other advantages or defects of the system are likely to be more studied.

While treating on this subject, I may say that other plants as well as Geraniums may be managed this way, as Verbenas, Heliotropes, and the like, but Petunias are so liable to become unwieldy at the neck that I have never done much good with them; but sometimes a row or two of something else than Geraniums is useful in separating two kinds from each other. This, however, and many other matters of detail will suggest themselves to the general manager. When moss falls short we have used short grass from the lawn instead, but it is not so good, and had better go to assist the heating material. Glass lights as covering have also been dispensed with on an emergency, and a rough framework to support mats at night has been adopted; it is needless to say this does not answer so well, but at a busy season all makeshifts have to be made use of, and the above taken as a whole is a recommendable one.—JOHN ROBSON.

NOTES AND GLEANINGS.

WE have received from the Hon. and Rev. J. T. Boscawen specimens of PARSONS' WHITE MIGNONETTE, which for length of spike, size and whiteness of the flowers, and delightful fragrance, exceeds anything in the way of Giant Mignonette we have ever seen. Its scent is not unlike that of Gardenia fragrans, and is quite as powerful. It is an invaluable strain, worthy of careful preservation.

—— MR. CANNELL of Woolwich has sent us flowers of the PELARGONIUM OBLONGATUM, a species with yellow flowers, which he has been distributing among hybridists for the purpose of producing a new race of Pelargoniums with yellow flowers. We hope to hear that the attempt has been successful.

—— THE superficial surface of the FLOOR of the Great Hall at Antwerp, in which the Flower Show was recently held, is 1763 yards. That of the galleries 599, making in all 2362 square yards, or nearly half an acre, under one roof. This information, which we could not get at the time of the exhibition, has been kindly sent us by Mr. Charles Gilbert.

—— THE Governor of the Bahamas reports that the CULTIVATION OF THE PINE APPLE is rapidly spreading through those islands. He saw last year what is probably the largest field of Pine Apples in the world. It is on the estate of Mr. Johnson, in the eastern district of New Providence, and from one spot could be seen at a single glance 1,200,000 Pine Apples growing. They were well weeded and in good order; and this broad expanse of young fruit, in its clusters of delicately-tinted but sharp and distinct leaves, gave a peculiar feature to the landscape. The Governor states that Pine Apples to the value of £53,497 were shipped from the Bahamas in 1873 to the United States and England. The inferiority of the Bahamas Pine Apples hawked about the streets of London to the hothouse Pine Apples of England is due to the necessity of cutting them unripe, that they may outlive the voyage.

GALEANDRA BAUERI.

THE Galeandras have had their generic name translated "Casquewort," because their flowers are shaped like a helmet or casque. Dr. Lindley mentions the species now before us as "Bauer's Casquewort." The specific name commemorates Mr. Francis Bauer, the botanical portrait-painter.

This Orchid was first discovered by Martin in French Guiana, but the first living specimen was sent to Mr. Barker from

Mexico by his collector Mr. Ross, who stated that he found it "at a place called Kisatipa, ten leagues from Melacatapec, and growing at the upper end of a dry ravine, terminating half way up the mountains, in a south-west aspect. The temperature varying from 69° to 77° Fahr. by day, and at night as low as 59°. The mountain surrounding this ravine, that is on the north-east side, is covered with a great variety of Orchideæ, whilst on the south side of the ravine there are none to be

Fig. 78.—Galeandra baueri.

found but a few Tillandsias. On the top of the mountain there is a continual mist all the year, from December to February excepted. The atmosphere is particularly moist and warm."

Although there are but few species belonging to this genus, and those few are but little known except in large collections, nevertheless the flowers of all of them are very pretty. G. Baueri is perhaps the most desirable. The prevailing colour of the flowers are pink. The whole plant is dwarf, not growing more than about 6 or 8 inches high. It may be cultivated in a pot or on a block, as shown in the illustration. The main obstacle in growing such difficult plants on blocks is that they are so apt to receive a check when making their growth if allowed to become too dry. If the plant is fastened to a

block it is necessary to place some sphagnum on first, and then fasten the sphagnum and the plant to the block with copper wire. If grown in a pot it ought to be quite three parts filled with drainage, and the compost should be sphagnum, turfy peat, and broken pots in equal proportions. When the young growths are being made the plant ought to be shaded from the sun and kept in a temperature of 65° at night. The leaves are easily injured, and must be kept free from insect pests at all times; but thrips and red spider must be carefully guarded against when the plant is making its growth.—J. Douglas.

SALVIA PATENS.

Both as a pot plant and as a border flower this well-known Salvia unquestionably possesses high merit. Twenty years ago it was more commonly met with than at the present day, yet in beauty it is not superseded by any other species of the same genus, or surpassed in colour by any flower that is grown in hothouse or garden.

As a conservatory plant it is deserving of more general attention than it receives, as contributing a colour that is not common to indoor plants, and which is fine by contrast with other flowers of the same period, and, more than this, one that is certain to be admired for its intrinsic richness and undoubted beauty.

The plant is of the easiest possible culture. It may be had in bloom over a long period of the year, and may be grown and flowered small in a 48-sized pot, or be increased to the size of a large bush carrying twenty or more spikes of bloom. It is thus adaptable to small or large houses, and to various purposes of decoration. It is a plant which, with gentle forcing, will fill an important place after the Cinerarias are over, and provide the colour which those plants have, in a measure, been wont to give, and which is too often absent in Pelargonium, Calceolaria, and Azalea time. For associating with those plants in June the Salvia patens is extremely well adapted, and cannot be too strongly recommended.

For this purpose stools, established in pots, have only to be introduced into gentle heat in February, and be placed in a light position, and by shifting-on they can be grown to any size required. If small blooming plants are preferred the young shoots can be struck in a brisk heat, when, by liberal culture and without any pinching or stopping, they will be in bloom in two or three months from the time of inserting the cuttings. Rich soil with an abundance of water are the main points leading to success. It should be stated that on breaking into growth the old plants should be carefully shaken-out of the pots and be repotted in fresh soil. When full of roots and in active growth they will require as much support as the Chrysanthemum. If this is denied them they will not only cease blooming, but will become infested by the red spider. As summer and autumn-blooming garden plants, rows, clumps, or individual plants in the mixed borders are very effective.

How much this plant delights in moisture was evidenced by the wet season of 1872, when it flowered uninterruptedly from July until destroyed by frost. Spring-struck cuttings of that year grew into plants of immense size, and bloomed profusely during the dripping period of that summer.

If required in a dwarf state the plants can be pegged down, but they are not suitable for filling-in a panel—not only because the growth is not close, but because during very hot weather, when other plants are in beauty, these are apt to drop their flowers, and would spoil the aggregate effect. It is for the conservatory, for lines in shrubberies, or clumps in mixed borders, that these plants are mainly suitable, and for such purposes they should be universally cultivated.

Their rich spikes are always in request as cut blooms, and they last a considerable time—in fact quite long enough—in water. For this purpose alone this beautifully blue Salvia should be provided. A lady armed with scissors and basket in seeking to decorate her apartments will never pass by this plant without a supply of its free yet imposing spikes of bloom.

A stock of this plant is easy to be had, for cuttings strike quite freely at this season, and it is also easily raised from seed. It is not a free-seeding plant, and not many can be expected from a small packet. What there are, however, are pretty certain in germination if afforded a genial heat and a sufficiency of moisture. Plants from seed flower the same season.

Its tuberous roots will, in dry soil, and if covered with ashes, survive the winter in the open ground; but it is altogether preferable to take them up and store in pots or boxes quite free from frost. The soil should never become dust-dry, or the roots will shrivel at the neck and the eyes will refuse to start in spring. This good old plant is commended to gardeners generally, and to admirers of blue flowers particularly, as worthy of extended cultivation.—A Surrey Gardener.

NOTES ON VILLA AND SUBURBAN GARDENING.

The Flower Garden.—Much activity will be needed in this department from now up to the time of bedding-out, not so much from this branch alone, but while this is going on other things must be thought of to produce a display of bloom after other plants are out; however, by dividing the subject, and beginning with the outdoor part, I may be better understood.

Dahlias.—If these have not yet been started into growth under glass, it would not be a bad plan to plant them out now where they are to flower. I have done so about this time for two seasons, not having room to do otherwise, and they have done well. Of course the ground must be well prepared and deeply cultivated for them, and well drained, so that the water, of which they require an abundance, may pass off quickly. A sheltered situation is the most suitable, on account of the brittleness of the wood and heavy foliage. In order to develope themselves they should not be less than 4 feet apart, and when planting cover the roots with a coating of coarse sand; but first add lime to the soil, in order to check the attacks of slugs when the young shoots begin to show. After planting, a covering of rough litter over a coating of coal ashes will protect them from frost; but when the shoots come above ground allow them full liberty in the daytime, but cover up at night until all danger from frost is over. Staking and tying will be a necessary operation in due time.

Gladiolus.—The principal lot of these must now be planted. The treatment as to soil is about the same as for the Dahlia, excepting that it should be fresh and not over-rich. The common or hardier sorts, such as Brenchleyensis, are not so particular as to soil-preparation as the newer and more tender varieties.

Carnations.—It is quite time that all those not intended for pot culture, and which have been kept in pots in cold frames all the winter, should be planted-out where they are to flower, and the others shifted into pots a size larger; or, if that has been done some time, the earth will need a little renewing. Picotees and Pinks must now be planted-out in the same manner, as well as most other perennial flowering plants, such as Sweet Williams, Lychnises, Campanulas, Columbines, Feverfew, Foxgloves, Hollyhocks, Canterbury Bells, Pansies, Sweet Rockets, Rose Campion; while other plants, such as Polyanthuses, Primroses, double Daisies, Thrift, Hepaticas, Saxifrages, and Gentianellas, ought to have been planted early in the autumn, as they are now at their flowering time.

After the above work is done, and in order to advance matters, all the flower beds that are to have raised edgings—as is the custom now in both small and large gardens, and which look uncommonly neat—if the plants to be used are either hardy or half-hardy they may now be planted. I allude to such plants as Echeveria californica, Echeveria secunda glauca, Gnaphalium lanatum, and plants of that type, which make suitable edgings, and will take no harm if put out now; and as the operation disarranges the beds, these can after this be the better prepared for the more tender plants to be planted hereafter.

The Indoor Department.—Here there is much to be done. The work of propagating, where the stock is yet short, must be carried on vigorously. The last of all to be propagated are the Alternantheras, Coleus, &c., because they from their tender nature cannot be trusted outdoors so soon as other plants—possibly not till the beginning or middle of June. If a quantity of these are required it will save time if they are put thickly into boxes instead of pots, and they will come out just as well at bedding time, Coleus excepted; these producing larger foliage, are more tender, and not quite so vigorous in rooting, will do best if each plant can have a pot to itself. Keep these and all other bedding plants stopped, so that they may make the better plants and cover more ground when planted-out. Pot-off or prick-out Amaranthuses, Stocks, Asters, Indian Pinks, Chilian Beet, Ricinus of sorts as they require it, and have all the bedding stuff into a settled condition as fast as possible, so that when another week or two has passed away all may be placed under temporary protection outdoors, and in a short time be finally hardened-off preparatory to being planted-out; this will leave room for such plants as ought to be seen to now in order to fill-up the vacant places.

The first of these is the Primula sinensis. Sow seed of the white and red separately in pans or pots half filled with drainage, the remainder finely-sifted peat and leaf mould half and half, with sufficient sand to keep it from binding. Do not fill nearer than within half an inch of the top of the pot; cover the seed thinly and water gently; cover the whole over with damp moss to prevent the soil drying too suddenly, which, as I have said before, after they have vegetated is very hurtful to them or all small seeds; place them in a Cucumber frame or where

there is a moist heat, and they will not be long in coming up. The moss must be taken off, and great care exercised in this young state. The sun is liable to scorch them off, therefore gentle shade is necessary until they are established in pots to themselves.

Those who grow Cockscombs will have a grand display in August by sowing the seed now, and raising the plants in a dung frame; sown in a similar manner to the preceding plant, but the soil may be a rich loam and not peat, and after this they need a strong heat to bring them to perfection, including a gentle bottom heat. It is a beautiful and lasting flower of easy culture, and I am afraid it is becoming neglected, hence my reason for calling attention to it. Balsams should also be sown now in pots of similar soil to the Cockscomb, and be grown on as fast as possible in a frame and kept near the glass to prevent drawing; but although these will thrive in a pit, they will take up much more room, and they also like a circulation of air amongst the pots as well as the branches when they have become established; if they are grown in a dung frame throughout, which is a very convenient way for those with small convenience, the frame must be set on bricks and elevated at the back to have the benefit of sun and light, and let the air circulate underneath the frame.

Gesneras and Achimenes.—These are very essential for late flowering, and the last of them should now be potted in light soil, shaking the old soil from the tubers and picking out the best for potting, setting several into the pot according to its size, and covering them over lightly, and start in the gentle heat of a frame or house. After the foliage is made keep the moisture from them while the sun shines, or take means to shade them, or the leaves soon become spotted and look bad. Some of the tall-growing sorts may require stopping in order to secure side shoots and dwarfness. This operation will necessitate their being kept in a growing atmosphere after the others have advanced more towards flowering.—Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

Casual allusion was made two weeks ago to protecting the blossoms of fruit trees from frosts. The fine weather we were enjoying at that time has been succeeded as usual by east winds and a much lower temperature. On Wednesday the 14th Fahrenheit's thermometer registered 5° of frost. Many of the standard Plums are in blossom; Plums, Cherries, and Pears on the walls are also either in full flower or are well advanced to that point. Now as to the means used to protect from frost. The trees are simply allowed to take their chance this year. When the weather is dry and the air still a few degrees of frost does little damage to the blossoms. The main object of placing screens over the trees is to keep the blossoms dry. A coping projecting from the wall 9 inches or a foot will do this to a certain extent, but it will not save the trees from driving rain, sleet, or snow. The canvas, as has been already suggested, must be arranged so that it does not touch the blossoms. Placing spruce branches amongst the blossoms has been recommended for wall trees and for small or medium-sized specimens in the open garden. They may do a little towards sheltering the flowers in a calm night, but even with a very moderate gale of wind they would be blown about amongst the blossoms, so that they would be very materially damaged. As to the trees in the open ground, unless they are small bushes or pyramids but little can be done to them to be effectual: if canvas is put over them it must be removed during the day. A few years ago we had a framework made and put over some of the choicest Pear trees; a canvas screen was made to pull over this and to fit tightly, and was allowed to remain over the trees from the time the first blossoms opened until the fruit was set. It was found on comparison that the trees uncovered were healthiest, and also that the fruit set best on the uncovered trees. Shading too closely predisposes the trees to the attacks of insect pests.

The operation of grafting should now be performed, Pears on the Pear stock, and Apples on any stock—Crab, Paradise, Doucin, &c. The grafts were saved at the time of pruning and stuck into the ground at the bottom of the trees. They are now starting into growth, but not so much as the trees to be operated upon. The methods of grafting described in horticultural works are very numerous, but two—viz., crown and whip grafting, are quite sufficient for all the purposes of the ordinary gardener. If it is necessary to head-down an undesirable variety of Apple or Pear the large branches must be crown-grafted. From two to four grafts may be inserted on each crown, and the *modus operandi* is very simple. Slits corresponding to the number of grafts to be inserted are made in the bark from where the branch was severed. The scions are prepared very much the same as for whip-grafting, and pushed down at the slit between the bark and the wood. Whip-grafting is adopted when the wood to be operated upon is the same or nearly the same thickness as the graft. It is only necessary that the bark of the scion and stock come in contact at one side; if it meets at both sides all the better. The scion is cut in a slanting direction, the cut to be about 2½ inches long, and a corresponding cut is made on the stock. The work ought to be done with a sharp knife, as the cleaner the cut is the better will be the union. It is also usual to make notches to correspond on stock and scion; but this is not necessary, as, if the work is well performed, the joining is so perfect that the wind will not break the tree over at the union.

FRUIT AND FORCING HOUSES.

Vineries.—The earliest house now receives more ventilation and less moisture in the atmosphere, as the fruit is colouring. The surface of the borders and paths are sprinkled with water daily, generally in the early part of the day. Were the days warmer more moisture would be applied. It is not possible to say how much moisture should be evaporated from the surface of paths, borders, &c., as the quantity required in a day of bright sunshine with a drying east wind is out of all proportion to the requirements of the house when the weather outside is of the opposite character. The borders outside (protected by waterproof shutters) and inside received a good watering with manure water. We calculate to give as much water at each watering as would correspond to a rainfall of 2 inches.

Guano of the best quality is a good stimulant for Vine borders; it is merely sprinkled over the surface before commencing to water, and the large quantity of water applied will carry the stimulant to a considerable depth. It is yet too early to remove all the covering from the outer border, but all the manure has been removed, except so much as covers the surface to the depth of about 3 inches. The shutters are still retained; in the daytime it would be as well to remove them, if they could be replaced again at night, but this makes too much extra work for us.

Examine all the laterals to see that they are firmly fastened to the wires, as the weight of the bunches not unfrequently break a weak fastening, and on one occasion we found a fine bunch of Muscats nearly ripe lying on the ground from this happening. Our lively little friend the red spider has appeared; it can be destroyed by painting the hot-water pipes with flowers of sulphur, soot, and a little soft soap; but great watchfulness is necessary, or the fruit may be injured. We generally make an attempt to wash the leaves by hand with a sponge and soapy water, but this is tedious work, and requires as much care as the other, as a careless person makes a sad mess of the bloom on the Grapes with his coat sleeves or by bobbing his head or hat against the bunches, or if he does not first wring the water out of the sponge mayhap the dirty soapy water is allowed to drip on the berries.

Late houses are now demanding all our attention in tying and training the growths. The instructions how to do this was fully described when the earlier houses were done. The inside borders have received two waterings with clear water; rain water is undoubtedly best, but owing to the deficient rainfall of the last two months we have had already to draw upon the pump for a supply.

If it is intended to inarch any of the Vines with another variety now is the time to look out for a suitable growth. It ought to be trained into the place where the new sort will occupy, and it must not be stopped at the same time that the side growths are. The intended variety may be grown on either in the same or in another house, and when both young rods are from 5 to 6 feet in length they may be joined together by slicing a portion about 4 inches long from each, fit them neatly together, and tie tightly with matting. In two weeks the fastening must be slackened, as the Vines grow rapidly. When the union has taken place the plant inarched from may be partially severed from the Vine close to the union, and in two or three weeks more it may be cut off.

As the weather is very changeable, much attention is required in airing and maintaining the proper degree of moisture.

Peach Houses.—In the earliest houses where the fruit is stoned and taking the second swelling a high temperature may be kept up with a corresponding amount of moisture in the house. Syringe the trees morning and afternoon, and if there is any traces of red spider the water must be applied with considerable force. The water should be exposed to the atmosphere of the house a few hours before using it. The best way is always to keep a pot or two filled; they may stand upon the hot-water pipes. The roots should have a good watering also at this time, and probably no more will be required until the fruit is gathered, when the border may have a good watering, and the leaves be thoroughly washed with the garden engine or syringe. When the fruit shows signs of ripening cease to syringe, and give more air, and reduce the night temperature to 60° or less, it may be 70° at the time the fruit is swelling.

GREENHOUSE AND CONSERVATORY.

Chrysanthemums now require considerable attention. Plants intended for specimens are now being potted and trained; it is necessary that they receive no check to their growth through becoming pot-bound, and the young shoots must be bent down

before they become too stiff. Plants grown to produce large flowers are not stopped at all, but the shoot is trained to a single stick. This plant is subject to the attacks of aphis, and this pest must be effectually destroyed before the plants are placed out of doors.

Lapageria rosea and L. alba are now making the young growths. These must not be allowed to twine together and round the wires, but must be untwined when they do so, and be merely tied to the wires. Knitting cotton is excellent for the young shoots to twine round, as if at any time it is necessary to remove or re-arrange the growth the cotton may be cut. Hyacinths and Tulips are now nearly over, but their place is well supplied by Cyclamens, Primula amœna, and varieties of it, the most distinct being the white and lilac sorts. Cinerarias are also indispensable at this time, the flowers lasting so very long in beauty, and are so well adapted for cutting from. In hot drying days sprinkle the paths of the houses with water in the forenoon.—J. Douglas.

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Manchester (National Auricula Show).—April 27th.
Jersey.—May 5th, Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.
Bath.—May 12th, September 1st and 2nd. Mr. B. Pearson, 13, Milsom Street, Sec.
Blackburn.—May 17th, 18th, and 19th. Mr. W. Ditchfield, Hon. Sec.
Crystal Palace Company.—Flower Show, May 29th; Rose Show, June 19th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.
Coventry.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.
Leeds.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.
Burton-upon-Trent.—June 16th. Mr. Wm. Shave, Bond Street, Sec.
Glasgow.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.
Fareham.—June 23rd. Mr. H. Smith, Sec.
Exeter (Rose Show).—June 25th. Mr. J. N. Gray, Queen Street Chambers, Hon. Sec.
Wisbeach.—June 30th. Mr. C. Parker, Hon. Sec.
Maidstone.—(Roses), June 30th, at Vinters Park. H. Benstead, Esq., Hon Sec., Rose Club, Mill Street, Maidstone.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Address (*J. Porter*).—We do not know to whom you refer.

Pansy (*H. W. M.*).—The colour of your Pansy, a reddish bronze, is not common, neither is it new. It is a little deeper than that of the variety called Annie. As the flower is of good form we advise you to preserve the plant as a parent for further improvement in rich colours.

Geranium Lucius.—"*C. R.*" asks, "Will 'Age' inform me where one can obtain in perfection plants or rooted cuttings of the Geranium Lucius he so strongly recommends in the *Journal of Horticulture?*"

Greenhouse (*N. P.*).—We cannot recommend. As you quote from Messrs. Boulton & Paul's catalogue, why not write to them? You ought to be able to decide for yourself from their well-illustrated catalogue.

Chicken Manure (*A. S.*).—You cannot do better than offer it to some market gardener or nurseryman near you.

Meadow Saffron in Pasture (*F. W. H.*).—The specimen you enclosed is the Meadow Saffron, Colchicum autumnale. Many cows have been killed by eating the leaves. The only effectual and cheap mode of destroying it is to employ some women to cut every plant down to the bulbs. Spuds and old knives may be used for the operation.

Destroying Insects (*R. T. F.*).—Any one of the preparations advertised answer the purpose. We cannot insert testimonials, for if we did so for one, others would claim that cheap mode of advertising.

Aughinburgh Blackberry (*J. H. W.*).—Some nurseryman at St. Francisco, California, could supply it probably, but we know of none.

Vines and Peaches Injured (*A. B. C.*).—There is not a doubt but the overheating would act injuriously upon both Vines and Peaches, but we are not prepared to say a morning temperature of 70° a week before the Vines flowered would so dry the atmosphere as to scorch the leaves, but we incline to the opinion that the pipes or flues have been so highly heated as to cause injurious fumes to be given off, and these would account for the condition of the leaf sent us. Scorched it is by some agency, it may be the overheating, an overdose of tobacco smoke, or the sun falling powerfully upon the leaves while wet. A temperature of 65° in the morning is 25° too high for Peaches in flower, and would be highly injurious to their setting, though we do not consider we should be justified in attributing the cause of the poor crop to it alone, as we know many instances of such mishaps in overheating occurring without being attended with such disastrous consequences as those you describe. The after-effects upon the Vines and Peach trees will not be permanent.

Melons and Cucumbers in a Small House (*An Amateur*).—Your small house will answer from May onward for either Cucumbers or Melons, the plants being forwarded in a bed, and strong before placing in the house. They may be grown in either pots or boxes, and the shoots be trained about a foot from the glass. Telegraph Cucumber would answer admirably for the house. Little Heath Melon would succeed well in a frame with fermenting materials, or it would do in the house, though Cucumbers and Melons are best grown separately.

Vines in Cool Vinery (*Idem*).—The Vines may be syringed in the evening, but we do not recommend the practice except when the Vines are breaking, discontinuing it so soon as they are in leaf. The floors, walls, and every available surface we should sprinkle with water at between 7 and 8 A.M. and at 5 P.M., damping the floor, &c., at noon in bright weather in addition to morning and evening, which is a better means of supplying moisture than by directly forcing it upon the foliage, and especially their under surface, by syringing. The Vines not having been pruned we should disbud so as to leave two buds or shoots from the base of each growth of last year if upon the spur system, or if rods, leave the shoots on opposite sides of the cane at 12 inches distance apart. We should have a thermometer in the house about its centre, and with its back to the sun. Give a little ventilation at 65° to allow of any accumulated moisture being dissipated, and allow the temperature to rise to 75° before increasing the air, and then admit it rather freely, not allowing it to fall below 75°, and with full air the temperature may rise to 80° or 85°, and in summer to 90° without injury, reducing the ventilation as the temperature decreases, and altogether by the time it declines to 75°, and if it rise to 80° after closing no harm will be done. If mildew appear dust the infested parts with flowers of sulphur. We could not give you the full treatment of the Vines; that you may learn from the "Vine Manual," published at our office, and to be had therefrom by post if you enclose 2*s.* 7½*d.* with your address.

Greenhouse Flue Heating (*B. B.*).—Your house may be heated satisfactorily by flues but not by one furnace, as it will require to be too highly heated, and at the furnace would be red hot, whilst the other end of the flue would be comparatively cool. To heat safely you would require two furnaces, and in this case it would be more costly than heating by hot water, which we advise. Two 4-inch pipes along the front at about 3 feet from the front wall and on the level would be sufficient in the severest weather to exclude frost. The front wall of the greenhouse we should have 2 feet above ground, then 3 feet of front lights, and the back wall will need to be 13 feet 6 inches high. The trellis for the Vines should be fixed 16 inches distance from the glass.

Grafting Vines (*Idem*).—Black Hamburgh may be grafted upon Buckland Sweetwater, and now is a good time to do it, the scions being in a dormant state. Both, however, succeed so well upon their own roots, that, except for changing kinds, the working of them is undesirable.

Asplenium Fronds Eaten and Browned (*F. W.*).—The most likely cause of the damage to the fronds is by snails or slugs, woodlice being also addicted to eat them. Examine the plants at night with a lantern, when you will probably find the depredators on or near the plants. The brownness we presume is that of the old fronds, which is usual at this time of year, they being soon after this replaced by new growth.

Camellias not Flowering (*Idem*).—The cause of the plants not flowering, or not forming buds, is due to over-vigour; but buds may be formed, and they may be cast, which is mostly a result of weakness and imperfect root action.

Sowing Aucuba Berries (*J. J. S.*).—You may sow the seed or berries without removing the skin and pulp surrounding the seed; but we think it just as well to remove it, and sow in rich light soil, and place in gentle heat; in about six weeks or earlier the seeds will be up, though we have known them not to germinate until the times you quote. In answer to the correspondents to whom you allude, the vagary is not ours; it is that of the seeds themselves. The uncertainty of growth is common to many seeds, as Palms, Roses, Hollies, Thorns, &c.; even the Primula japonica we have had up in little more than a week after sowing, and at another time the plants have not appeared under twelve months.

Lawn Sand (*C. A. J.*).—Write to the proprietor, who advertises in our columns.

Seakale (*Chippenham*).—Plant at once young roots, not more than one year old, but if convenient leave the old roots for another year, and after cutting throw them away. You will then have a vigorous young plantation to give a full supply for many years. Seed sown now in rich soil, breaking the outer shell of the seeds, will in two years give an abundance of fine crowns for regular forcing.

List of Orchids (*F. L.*).—About seven of the species named may be depended upon to flower between the 1st of November and the first day of April. Fourteen are what are termed cool-house Orchids, the remaining twelve being adapted for the intermediate house. The cool house ought to have an average minimum temperature of 45° during winter, the intermediate house an average of 55°. None of them will succeed in a cool greenhouse. The ordinary occupants of a greenhouse require more air and a much drier atmosphere than is necessary for Orchids. We advise you to build a small house specially adapted for cool Orchids. Unless you do this your success will be more than doubtful. The plants are cheap enough if they are healthy, but we would not purchase an Orchid unless we first saw the plant. We also think it right to inform you that the best cool-house Orchids are omitted in the list, such as Cattleya Skinneri and C. crispa, Epidendrum aurantiacum and E. prismatocarpum, Lælia autumnalis, L. majalis, and L. superbiens; Lycaste Skinneri, and the many fine varieties of this useful Orchid; Masdevallia Harryana which is now cheap; Odontoglossum crispum in variety (this is the best cool-house Orchid, indeed it is the most useful of all Orchids); O. triumphans, O. Insleayi and varieties—this is a fine winter-flowering species, as is also O. nebulosum; Oncidiums such as O. bifolium majus, O. hastatum, O. macranthum, O. nubigenum, O. Phalænopsis, and O. tigrinum. All the Pleiones are winter-flowering and adapted for a cool house. Sophronites grandiflora and Stanhopea tigrina are also suitable. We advise you to purchase good plants, they are cheapest in the end. The best dwarf tree Carnation is Miss Jolliffe. Picturata is also dwarf and very pretty. You ought to have the Scarlet Pink "coccinea."

Beginning Gardening (*T. M. B.*).—You seek for information too extensive

to answer in our columns. Our "Garden Manual" contains all that you ask for and much more. You can have it free by post if you enclose twenty postage stamps with your address. Your poultry query will be answered next week.

Snowdrops, &c. (*O. W. D.*).—We cannot state the addresses. It is most annoying to amateurs to have to answer applications of the kind you intimate.

Waxen Daffodil (*R. S. S.*).—The specimen you enclosed under this name is, we think, the Musk Narcissus, Narcissus moschatus. It is figured in the "Botanical Magazine," t. 924.

Pyrus (Cydonia) japonica and Sweet Bay Propagation (*S. B.*).—The former may be increased by cuttings of young well-ripened wood put-in in October after the manner of Rose cuttings—*i.e.*, having one or two eyes above, and 8 or 9 inches within the ground. They are a long time in rooting, often more than twelve months. Layering in the autumn is a more certain mode of increase. Sweet Bay is increased by cuttings put in under handlights at the end of September, securing a heel of old wood at the base of each cutting. The cuttings of both should be put-in firmly in gritty soil.

Wild Primrose (*J. Rogers*).—The flower you have sent is a case of duplication in the Primrose, wherein there are two pistils, double the usual number of stamens and segments of the corolla. We fear it is not likely to be permanent, and we suspect all the flowers on the plant are not of a similar character. If they are it will be an interesting variety.

Insects Attacking Pot Vines (*An Old Subscriber*).—The white grubs which are attacking and destroying your pot Vines are the larvæ of the voracious weevil, Otiorhynchus sulcatus. As they are easily seen and do not bury themselves deep in the earth, they may be found by a careful removal or sifting of the soil round the crown of the roots of the plants. This should be burnt or well soaked with gas-tar water. The brown beetles which are the perfect state of these grubs are much more difficult to discover, but may be caught by laying a sheet round the stems, and visiting them with a light after dark, when they are alarmed and fall to the ground.—I. O. W.

Names of Plants (*T. W. C.*).—Justicia carnea, Flesh-coloured Justicia. It requires stove culture, being a native of Rio Janeiro, whence, in 1827, it was sent to the Royal Horticultural Society. (*I. W.*).—The tree is the common Alder, Alnus glutinosa. (*Conc*).—The large-coned specimen is Picea Nordmanniana. The other we do not recognise.

POULTRY, BEE, AND PIGEON CHRONICLE.

HOW TO BUILD A PAIR OF FOWL HOUSES.

I send a general description with a few plain directions, "how to build a pair of semi-detached fowl houses." The accompanying plan and elevation are on one-eighth of an inch scale.

The fowl house is situated in an orchard facing the south, the run of one measures 130 feet by 40 feet, the other 260 feet by 40 feet, part of the distance being 80 feet wide at the end surrounded by a wire fencing, except the outer side which is a wooden fence 8 feet high. The fowl house is 24 feet wide, 6 feet deep, 6 feet from ground to eaves, and 8 feet to ridge of roof inside at each end of the building, and under the same roof there is an open shed 5 feet 9 inches square (inside measurement), the remaining 12 feet are the two fowl houses divided in the centre. A door leads into each compartment, approached through the open shed with a hole in the door for the fowls to pass through, as seen by the elevation. The laying nests are upon the floor with perches so arranged as not to be any annoyance to the fowls' nests. The floors of fowl house and sheds are laid with 4 inches of broken chalk and sifted cinder ashes mixed together, well rolled and beaten down, then copiously watered with a garden water can, making when dry a firm and capital floor. A dust bath is also provided in each of the open sheds.

The outer walls of the house are built with feather-edged 9-inch deal boards, overlapping each other 1 inch, also the two ends of each fowl house up to the doors. The inside of fowl houses are lined with three-quarter-inch white 9-inch deal boards. The doors are 2 feet 3 inches wide, and 5 feet 9 inches high. The window is glazed and fixed to give light to both houses. The roof thatched with wheat straw of good thickness, and overlapping the outer walls about 9 to 12 inches.

I very much prefer straw thatch to any other kind of covering for the roof, ensuring an equable temperature summer and winter. The arrangement of the double walls in the two houses ensures a capital ventilation, the chalk floor adds greatly to the comfort and health of the fowls.

Having given a general description of the houses I will as clearly as I can state a few plain directions how I set about building them. I must presume my reader has decided to be his own architect, surveyor, and builder. Let us now take a walk to the timber merchant, and let him understand we are to be put on the best terms for cash payment, the order will be as follows:—

	£	s.	d.
9 by 12 feet deals, 4 cut feather-edged	1	16	0
6 by 12 feet white deals, 4 cut plain boards	1	4	0
50 feet 4½ by 3 five supports for top of roof, marked E, 10 feet each	0	8	6
105 feet 4½ by 3 for posts to support the walls and eaves of roof	0	17	6
24 by 5 feet, 2½ by 1½ for the rafters	0	9	0
2 by 12 feet, 3 by 1½, for top of roof fixed on the 5 by 8 feet posts	0	1	6
4 by 12 feet, 3 by 2½, for top of front and back posts	0	4	0
	£5	0	6
Nails, hinges, locks, glazed second hand window, chalk, straw, and thatcher	2	0	0
	£7	0	6

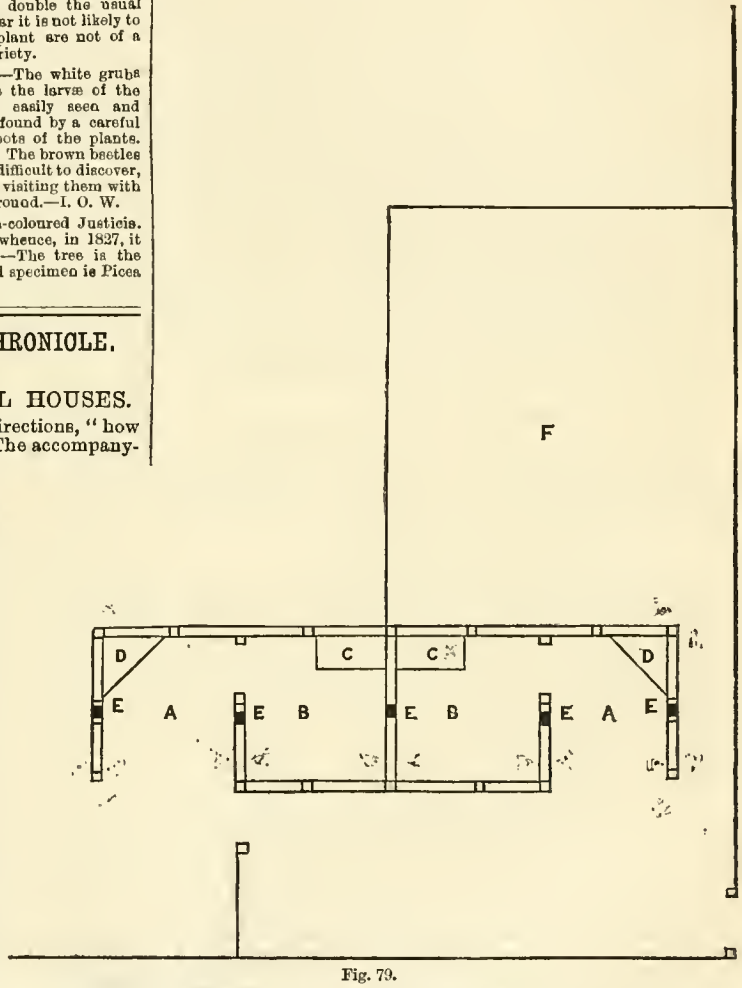

Fig. 79.

A. Sheds open to the south.
B. Fowl houses 5 feet 9 inches square.
C. Nests upon the floor.
D. Dust baths.
E. Centre posts.
F. Run enclosed with wire netting.
□ Gate.

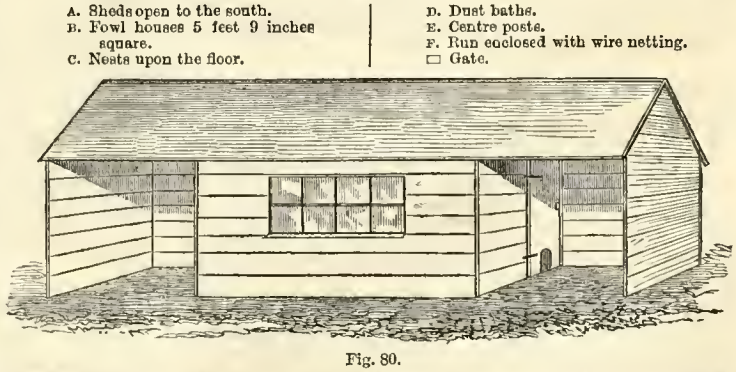

Fig. 80.

The above goods, &c., having been sent in I must refer to ground plan (fig. 79), which shows there are fourteen posts to support

eaves of the roof and the walls of the building, divided by 14 gives 7½ feet to each post, the holes to receive them to be dug 18 inches deep. Be as careful as possible in fixing the four corner posts that they are perfectly accurate, then proceed to dig the holes the same depth to receive the remaining ten posts.

Having fixed the posts for the outer walls then proceed to dig five holes 2 feet deep, for the five centre 10 feet posts marked E, leaving 8 feet above the ground to support the top of roof; when securely done take two 12 feet, 3 by 1½, and let them in at the top of the five centre posts. Proceed next to fix 2 12 feet, 3 by 2½ at the top of the front posts, Nos. 1, 14, 13, 12, and 11, and 2 12 feet, 3 by 2½ on the top of back post, Nos. 2, 3, 4, 5, 6, 7, 8, 9, and 10. All is now ready for the rafters, 24 by 5 feet, 2½ by 1½, half in front half at the back.

The skeleton of the building is now ready. Begin next with fixing the feather-edge boards, 9 by 4 cut deals gives five boards to a deal, or forty-five boards 12 feet long, 9 inches wide, allow 1 inch for overlapping, takes nine boards all round, rather more for the gable ends, 12 feet boards is a convenient size, cut them in half they fit the two ends, and cut a board in three will be rather more than enough for the two ends of the fowl house. Under the shed allow 2 feet 3 inches for doors. Next proceed with fixing the glazed window 4 feet by 3, or any other convenient size and pass to the inside of the house; first fix a double lining of boards for the centre to divide the two houses, and then line the inside back, front, and gable end walls, use the wood for the purpose from the 6 by 12 feet white deals, four cut plain boards, you can make your doors from the same, and fix them with ordinary hinges and locks. Place your perches in such a position as shall be for the comfort of the birds, so as not to interfere with the nests upon the floor, place the dust bath under the shed in the corner opposite the doors. Everything is now ready for the thatcher. Make a bargain with him at so much per 100 square, and use the best wheat straw. For the outer wall of house I have found pine varnish a cheap and excellent substitute for paint. Paint or tar is very objectionable for fowl houses. The cost will be 2*s*. 6*d*. or 3*s*.—J. P. Miller, *Enfield*.

SIZE AND TREATMENT OF BANTAMS.

In rearing these interesting pets the chief aim is to maintain the diminutive character or to reduce the size, if possible, as they seem to possess a natural tendency, under ordinary treatment, to exceed their parents in proportions, which they generally do, unless prevented by scientific means.

The prevailing idea is to accomplish this by late hatching, which has the effect intended in some cases, marred perhaps by preventing at the same time the complete growth of the late tail feathers, which will be considered a defect in the show pen; so that this plan of depending on the effects of cold weather to stop the growth may be considered as only partially successful. Another process for accomplishing this object is to diminish both the quantity and quality of food, which seems readily to occur to amateurs; but as some varieties of the Bantam class are somewhat delicate, the partial starvation process has the effect of either causing them to become still more so, or of eventually killing them. They really require a stimulating and nourishing diet, selected with a view of rejecting the bone-forming ingredients. The first soft food for tender young chicks should be bread crumbs scalded with milk, and then squeezed nearly dry, so as to readily scatter in fine bits, for which the birds have a decided relish, not forgetting to mix with this food a little pepper for the weakly birds, especially during cold and stormy weather. To follow this feed, say after they are four or five days old, we would recommend well-boiled rice, salted to taste; when nearly cold incorporate it with sufficient coarse ground barleymeal, and occasionally a very little oatmeal, to form into crumbs or pellets, which may be fed without waste, a little at a time, and as often as relished; which, with the addition of other food which does not make bone rapidly, will carry them through either early or late seasons most successfully and humanely.—(*American Fanciers' Journal*.)

GREAT HARWOOD SHOW OF POULTRY, &c.

The Show of the Great Harwood Agricultural Society was held on the 15th inst., being somewhat earlier than in some previous years. The entries for poultry were not large, but many of the classes contained good specimens. Single *Game* cocks were poor, but the class for pairs made amends, the first-prize pair being about the most stylish pair of chickens we remember to have noticed last season, as also in head and colour properties. The second were adult birds, the hen a gem, cock good in colour, but not in good order, and without one sickle feather. Highly-commended pen good in all points but the cock's breast, which was too red. Gold-pencilled *Hamburghs* good; the first-prize pen about perfect, as also the Silvers. The Gold-spangles very good, notably the first-prize hen, which is about the best we ever saw. Silver-spangles were a good even lot, and all noticed. In *Cochins* all were poor except the winners, which were Partridge. *Dorkings* had, but *Spanish* good, the hens especially, although the first-prize cock was a capital bird. *Brahmas* were a bad lot with the exception of the three noticed pens, Messrs. Ansdell's and Smith's pens being empty. In the Variety class Malays were placed first and Black Hamburghs second; there were some good Houdans, except that they had the Crêve comb. Single *Game Bantam* cocks were not a good class, Black Reds winning first and second. The next class was, however, better, the first going to a grand pair of Black Rose-combed, second to good Piles, and third to Brown Reds; we would, however, advise a revision of these classes. *Geese*, *Turkeys*, and *Ducks* were few in number, but the birds good in most of the classes. In the Selling class a nice pair of Partridge Cochins were first, and Gold-spangles second.

Pigeons were a good entry, many of the classes being heavy. Ponter cocks were first. The pens for this variety being rather too small they did not show well. First was a good Blue, and second a Black Pied. In hens a smart Blue was again first, and White second. In Carrier cocks both the winners were Duns; the first a large and strong young bird, second good in all points but eye-wattle, which was a little deficient, the others noticed being Blacks. In hens the first was Black, and second Dun. There was but one class for Tumblers, the first award being made to a capital Almond cock, and second to a Kite, a Blue Bald being very highly commended. Barbs a good class. First a Red cock, evidently young, about perfect, and in the pink of bloom; second a Red hen, good in all respects, but not in as fine order as the above. The whole class noticed. English Owls a fair class of twenty-two entries, the winners Blue cocks, the first a perfect-headed bird, but would be all the better of a little more gullet. Dragoons were very even in quality, and the contest was close, first and second being carried off by Blues, and third by a Red. There were, however, several birds that partook too much of the style and carriage of a Carrier. Antwerps a fair class, Silver Dun Short-faces being the winners, several otherwise excellent birds showing an inclination to a purl or frill at the base of the gullet. For Fantails the pens were rather small, so that the birds did not show well; the winnors were White. Trumpeters very good; first Mottles and second Black, all the class being highly commended. Nuns good and clean, and the winners free from trimming. Magpies also a good class, the winners, particularly small and neat, were—first Red, second Black. In the Variety class the first was a good White Owl, and second a Black Fairy Swallow; and in the Selling class the prizes were awarded to a Red-splashed Tumbler and an Archangel.

In Rabbits the Lop-eared class was unsurpassed by any we have ever seen at an agricultural show, every specimen being full of character. First was a Black-and-white Lop, not one of the largest, but of high quality, well marked and particularly silky in ears, 22 by 4¾; second a Tortoiseshell in fine bloom, 21½ by 4¾; third, the largest Rabbit in the Show, fine and sleek, but short in ear—viz., 20¾ by 4½, a Tortoiseshell; very highly commended a Black-and-white doe, by far the best in the Show, but in woeful condition, 22½ by 4¾. This we were informed was the cup-winner at Hull, but the condition must be altered ere she can win again. The highly-commended Rabbits all measured well, and it would not have been difficult to find places for many other prizes. In the next class first was a fairly good Himalayan, second a pretty good Belgian Hare, and third an Angora, this class completing the list. The birds were well attended to by an excellent staff directed by the Hon. Sec., Mr. Aspinal Clayton, in whose hands the sole management was invested.

Game.—1, W. Ormerod, Todmorden. 2 and *hc*, C. W. Brierley, Middleton. *Cock*.—1 and 2, C. W. Brierley.

Hamburghs.—*Golden-pencilled*.—1 and *hc*, G. & J. Duckworth, Church. 2, H. Pickles, Earby, Leeds. *Silver-pencilled*.—1, J. Robinson, Garstang. 2 and *hc*, H. Pickles. *Golden-spangled*.—1 and 2, G. & J. Duckworth. *hc*, H. Pickles. *Silver-spangled*.—1, J. Fielding, Newchurch. 2, J. Robinson. *hc*, H. Pickles; J. Fielding.

Cochin-Chinas.—1, A. Bamford, Middleton. 2, T. Aspden, Church. *hc*, R. Bowker, Billington; R. Holding, Oswaldtwistle. *c*, R. Bowker.

Dorkings.—1, J. Stott, Healey 2, W. H. King, Rochdale.

Spanish.—*Black*.—1, E. Siddall, Rawtenstall. 2, G. Barnes, Blackburn. *hc*, G. Barnes; D. Ashworth, Great Harwood.

Brahmas.—1, C. Holt, Rochdale. 2, R. Ryding, Eywood, Blackburn. *vhc*, G. Barnes.

Any other Variety.—1, J. Sanderson, Downham. 2, J. Robinson. *hc*, H. Pickles; G. Anderton, Accrington.

Game Bantams.—1, G. Anderton. 2, J. Saul, Preston. *hc*, W. Shenton, Lancaster. *c*, R. Almond, Salford; Billingham & Co., Burnley.

Bantams.—1, J. A. Dakin. 2, F. Steel, Halifax. 3, Billingham & Co. *c*, A. Taylor, Blackburn.

ANY OTHER VARIETY.—1, T. Charnley. 2 and *vhc*, J. Richmond. *hc*, J. B. Bowdon; A. A. Vander Meersch; J. Gardner; W. Dugdale.
SELLING CLASS.—1, W. Dugdale. 2, J. Richmond. *hc*, H. Crosby; A. A. Vander Meersch. *c*, S. Lawson.

RABBITS.

LOP-EARED.—1 and 2, J. Irving, Blackburn. 3, H. Prickworth, Moulton Marsh, Spalding. *hc*, T. & E. J. Fell, Blackburn; J. Irving; A. Shaw, Blackburn; H. Prickworth
ANY OTHER VARIETY.—1, F. Stansfield, Clayton-le-Moors. 2, J. Irving. 3, S. Buckley, Rochdale. *hc*, J. Irving; H. Prickworth.

JUDGES.—Mr. Simon Fielding, Stoke-upon-Trent, and Mr. Edward Hutton, Pudsey.

MORPETH SHOW OF POULTRY, &c.

THIS was held on April the 10th in the Corn Exchange, a place admirably adapted for the purpose. The Committee of Management being nearly all working men, it was gratifying to find their endeavours meeting with such an amount of success. To keep down expenses, everything connected with the Exhibition was done by themselves, and done well. The pens were arranged in the best possible manner; the birds were well attended to, and so were the visitors; the managers were courteous and obliging to everybody; and everybody was pleased. Such a Committee deserve success; and under their management the Morpeth Show should rise to an important position.

Cochins and *Brahmas* were good classes, the winners being large well-feathered birds. Only one pen of *Dorkings* was exhibited, which, however, deserved the first prize awarded to it. *Hamburghs* always muster well in Northumberland, and they were quite up to the usual standard here. The *Game* classes were large, and contained many excellent birds. Game *Bantams* are the pets of the district; and we were not surprised to find so many grand birds among them. The winner in the single cock Bantam was one of the best Black Reds we ever saw, splendid in feathering and style. The winners in the Variety class (Bantams) were all Black. Single cock class was won by a grand Buff Cochin; second Brahmas. Any variety was won by Golden-spangled Polish; Crêve-Cœurs being second. There was only one class for *Ducks*, which doubtless limited the entries; good Rouens took both prizes.

Pigeons were well shown, Pouters, Carriers, Owls, Turbits, and Magpies being exceptionally good.

There was only one class for *Cats*, and the Judge had considerable difficulty in deciding on their merits. The winner was a large black-and-white, with a fine skin; second and third beautiful greys.

COCHINS.—1, W. Swann, Bedlington. 2, W. Newbegin, Newcastle.
BRAHMA POOTRAS.—1, T. Oliver, Burradon Colliery. 2, W. Swann.
DORKINGS.—1, W. Swann.
SPANISH.—1, T. Oliver. 2, R Smith, Bebside Colliery.
HAMBURGHS.—*Golden-spangled*.—1, A. Stephenson, Dudley Colliery. 2, T. Marshall, Mitford. *hc*, J. Morton, Choppington Colliery. *Silver-spangled*.—1, W. Johnson, Cowpen Colliery. 2, W. Nixon, Morpeth. *Golden-pencilled*.—1, D. Chyne. 2, T. Marshall. *Silver-pencilled*.—1, Davison & Pattison, Bebside Colliery. 2, J. Morton.
GAME.—*Black or Brown Reds*.—1, T. Middlemiss, Seaton Delaval. 2, C. Taylor, Sunderland. *hc*, J. Young. *Any other variety*.—1, T. Young. 2, J. Douglas, Cambois Colliery.
BANTAMS.—*Game*.—*Black or Brown Reds*.—1, G. Bell, North Seaton. 2, G. Dowie, West Sleekburn. *hc*, J. Short, Bedlington; T. Heslop, West Sleekburn. *Any other variety except Game*.—1, J. Durning, Cambois, Blyth. 2, D. Chyne. *hc*, J. H. Law, Birmingham.
BANTAMS.—*Any variety*.—*Cock*.—1, G. Dowie. 2, W. Swann. *hc*, E. Rutherford, Sleekburn Colliery.
ANY VARIETY.—*Cock*.—1, A. Stephenson. 2, T. Oliver. *hc*, J. Stark.
ANY OTHER VARIETY.—1 and *hc*, R. Parsons. 2, W. Atkinson, Morpeth.
DUCKS.—*Any variety*.—1 and 2, W. Swann.
SELLING CLASS.—1, J. Young. 2 and *c*, H. Sharp.

PIGEONS.

POUTERS.—1 and 2, H. Simpson, Shankhouse.
CARRIERS.—1, H. Simpson. 2, W. Nixon.
OWLS.—1, E. Walker, Hexham. 2, T. Arkle, Morpeth.
FANTAILS.—1, H. Simpson. 2, P. Wilson, Pegswood.
TURBITS.—1, H. Simpson. 2, P. Wilson.
NUNS.—1 and 2, P. Wilson.
MAGPIES.—1 and 2, P. Wilson.
DRAGOONS.—1, E. Walker. 2, T. Arkle.
ANY OTHER VARIETY.—1, H. Simpson, Shankhouse. 2, P. Wilson. *hc*, S. Hume, Morpeth.
SELLING CLASS.—1, P. Wilson 2 T. Gardiner, Swalwell.

CATS.—*Any variety or colour*.—1, F. R. Nichol, Morpeth. 2, Miss M. Nich Morpeth. 3, T. Marshall, Mitford.

JUDGE.—Mr. F. E. Schofield, Morpeth.

THE COMMON PIGEON.

MUCH has been written on what are called "fancy Pigeons," and much has been done for their preservation. Their value tends to this, and as well induces fanciers to search even in foreign lands for them. They have many admirers, and their various characteristics attract the attention of the most cursory observer. But what of that beautiful bird the common Pigeon? In my wanderings in other cities, as time permits, I call at the various bird shops, where, if nothing new is to be seen, there is still no lack of interest, and there I am sure to find what I am told are "only shooters." It often makes my heart sad to see them (and I am often tempted to call in the police) undergoing the first of the agonies to which too many—aye, far too many—of those poor things are doomed. Just look at them: one, two, or three dozen pent-up, closer than penned sheep, in some old cage, basket, or box; they have fought themselves tired; those feathers which the highest authority has described as being "covered with yellow gold" are ruffled, torn, and dirty; they have had no food or water for no one can tell how long; they are and have been in a state of semi-starvation. And what is their end? They are carried out to some open part of the country, each bird placed in a small condemned cell called a trap, and when it emerges into supposed liberty, unless the executioner fails in his aim, end their miserable existence by fluttering downward to the earth, wounded, bleeding, and dying; and what is all this to satisfy? The vicious appetites of heartless men, and I feel forced to say also that women patronise this so-called "sport" by applauding the performances of their friends. Were those men and women the roughs or scum of society there would be some excuse which I could bring forward; they are not of this class, but of the class known as ladies and gentlemen, and no doubt also professing christians.

Were those poor birds shot for the purpose of augmenting the food of the country some excuse, paltry however it might be, could be set up; but it is not for this purpose, it is a "sport," so called and reported in the newspapers. If this is not "cruelty to animals" I don't know what is, and it is time that the Society for the Prevention of Cruelty to Animals took the upper hand in this matter. Our national poet, on seeing a wounded hare limp past him, wrote on the act of the sportsman—

> "Inhuman man! curse on thy barb'rous art,
> And blasted be thy murder-aiming eye;
> May never pity soothe thee with a sigh,
> Nor ever pleasure glad thy cruel heart!"

I would not go so far as this, but I think the man or woman who can make this cold-blooded cruelty a "sport" or pleasure can have very little heart, and deserves very little sympathy.

If they will amuse themselves by hitting something in motion in air, let some one toss up an old shoe for them and try at that, or anything else they choose, but pray spare the life of an innocent bird.—JAMES HUIE.

ENGLISH OWLS.

MANY thanks to "WILTSHIRE RECTOR" for his few encouraging remarks upon English Owls. Indeed, when we find also two of our best Pigeon Judges, Mr. Esquilant and Mr. Jones, with their many opportunities of seeing and comparing all the varieties, both admirers and breeders of the English Owl, we do not anticipate this breed will ever be talked or written down by gentlemen who are endeavouring to wipe out a variety which is a source of pleasure and interest to a large number, and which, in spite of the increase and spread of the "African," is becoming more popular every day, as may partly be seen in the increasingly well-filled classes when provided for this breed.

The arguments of Mr. Lyell against the English Owl are chiefly based, as stated by him in his last sentence, upon what he has read in a book published one hundred and ten years ago. Does Mr. Lyell mean to say that during this more than a century the whole Pigeon fancy has been at a standstill, and that what was then described as a short-faced bird would be short-faced now, or a small Tumbler then a small Tumbler now? Of course there may have been a few really small Tumblers—weakly birds like the often one unfortunate in a brood of chickens or a litter of pups—but I am sure the average size would be far above what Mr. Lyell would lead us to believe by his quotation; and as for the general point, all the really old representations I have seen are far behind the best birds (I am speaking of all varieties) of the present day, and even if there are any good plates, they only represent ideal specimens. I am sure that fancy Pigeons a hundred years after this, though they may be vastly superior to those of the present day, will not excel those represented in the plates in Mr. Fulton's book. Perhaps some now young faucier will fifty years hence be pointing to these plates, and with a sorrowful shake of the head saying, "See what they were like in my days; then Pigeons were Pigeons."

To return to Owls in particular. I cannot be persuaded otherwise than that the English and the African Owls are quite distinct varieties. The English variety is mentioned long before the Africans were known, and the latter are mentioned in Mr. Tegetmeier's Pigeon book as being a great curiosity when introduced at a comparatively recent date. It is certainly curious if our English birds are, as stated, degenerate descendants of the little Africans, how the latter can have been lost sight of during so many years. Then the colours are against such a supposition. In Africans we have black, blue, and white, principally the last colour; while in English we have blue, yellow, and especially silver and powder blues, while whites and blacks are scarcely ever seen.

To sum-up, Mr. Lyell, as a fancier, no doubt knows that perfect specimens are not to be met with every day, but if he will "just hae patience" he will find that there are pure English Owls to correspond with the description in his quotation, if, as I understand it, the beak referred to means such as is seen in what is called a down-faced bird (and therefore resembling the Owl), not an overgrown upper mandible, which is, of course, a malformation.—T. G. Sprunt.

ARTIFICIAL COLOURING OF BIRDS.

To-day I had the pleasure of a call from Mr. Gresham, who, while admiring a Yellow Pouter in my aviary, said, "Do you use cayenne?" At one time I did think of trying it, but gave up the idea, as I do not like anything artificial tending to alter the colouring of Nature in birds. Indeed, however much natural colouring may be intensified by art, whether by external application, or internal by means of feeding, it appears to me, after all the trouble, to be but a hollow victory, a transient show. The application must be repeated each year with more or less success.

It is now some time since a great deal of fault-finding was made against certain of our Canary breeders. Some thought their birds were painted, others coloured with dye, and others that the sand used in their cages was the cause of the high colour in their birds. To test this matter even chemists were employed, and because of those surmises, if I recollect rightly, a degree at least of dishonesty was attributed to the owners. I would not be so uncharitable as to say that there was a species of envy shown on the part of the fault-finders, but by-and-by it came out that no external colouring had been used, but that any amount of internal colouring matter had effected the purpose; and strange, at least to me, this internal artificial colouring has been very generally adopted by breeders of certain varieties of Canaries, and many of their birds have taken highest honours at shows. So far from this being challenged by exhibitors or judges it is now quite understood; the birds are called "hot-fed" birds, and the best dyer has the best prize. Now, I should like much to be enlightened upon the difference between the effect of outside and inside dyeing or artificial colouring. It looks to me one and the same, and puts me in mind of the Irishman at the railway station, who politely said, "Will you show me the entrance out, sor?"

Supposing this process could be extended to the colouring of Pigeons of all or any colour, it would become a very dangerous weapon in the hands of the unprincipled. We could never be sure of the colour of the birds we were purchasing; besides, it would have the effect of putting an end to our shows, and reduce our fancy from a science to a mere piece of mechanical jobbery.

I used to be largely in the Canary fancy, and still have a great leaning towards it; and were I in it again should try to produce birds of high colour without any artificial means beyond the process of selection. I think this artificial system of colouring should be discouraged. It could be done, though not easily I will admit, but the sooner the better if colour is so essential to carry the honours. While naming colour, as an old Canary fancier allow me to say, though I throw cold water on no one's fancy, that I do not see so much in the mere colour of a bird, particularly of a Canary—*i.e.*, in the intensity of colour. I think there is far more in shape, marking, and size. The German Canary I keep for song only, and I think, and one of the best judges in England of Canaries agrees with me, that there are only four varieties of Canaries worth the breeding.

First of all the Belgian for shape. There is grace in every line and elegance in every motion; he is the highest-bred bird of all. Second, the Lizard for markings; beautiful, trig, and unique in all his markings and colour, whether silver or golden. Third, the Lancashire Coppy, Crested or plain for size, and, as the gardeners say, for substance. He is a striking bird to the most cursory observer; and last, the German for his song. What his origin has been I cannot tell, but he and the Norwich, to my eye, are much of the same make.

Now, some of my friends will say I am down on the Norwich. Not so; but I can see no difference in form between the German bird, the old-fashioned Canary, and the Norwich. Will anyone enlighten me? Being exceedingly practical, I should like to see specimens if told there is a difference.—James Huie.

SELECTION OF CANARIES FOR BREEDING.

Although of the greatest importance many make but sorry work of it, pairing with little consideration as to the result; consequently after all their care and expense they are disappointed by continually producing birds below their ideal standard.

It is not in every instance that like produces like. Birds that have gained a season's honours frequently disappoint those who purchase them by throwing a degenerated progeny, whilst other birds who possess no such evident qualifications to recommend them frequently produce some of the best representatives of their variety. This is to be accounted for by the fact that many prizewinners are the results of cross-breeding.

Our endeavours should be by constant selection to secure a pedigree stock with known qualifications. Every pair of birds should be matched with a definite object in view. Peculiarities may be perpetuated and thereby made to become properties of the highest order, for they may be so inbred by selection as to establish decided varieties.

As an illustration we will endeavour to trace the origin of one of our known varieties, and for this purpose cannot make a better selection than the Cinnamon, which has made rapid progress toward excellence during the last few years. This variety has been acknowledged to have originated in the bronze green, and through an intermediate variety ultimately to have arrived to its present state. Carefully examine any cage of ordinary mixed birds not giving very decided indication of extreme cultivation, and it is more than probable that you will discover some of the Greens with very decided indications of cinnamon colour: this frequently exists about the back and lower extremities of the body. Assuming that we start with a few selected pairs in which this peculiarity existed in the highest degree, it is more than probable that some birds would be produced partaking in a greater or less degree of these peculiarities, but more fully developed; and by again selecting those approaching nearest the ideal sought we shall continue to strengthen the power to produce the wished-for qualities. But during this process of in-breeding we have degenerated in general physical qualities, which by judicious crossing we are enabled to remedy, and at the same time add to the progeny of such birds properties not hitherto possessed, but which in combination with the cultivated peculiarities of the original birds have produced the variety now distinguished by the designation of Cinnamons.

Yet it is by no means positive, if we continue to breed direct from the progeny of the last crossing, that we shall perpetuate this excellence. It is necessary that the effects of the cross-breeding should be toned down.

That the yellows and greens are incorporated in this variety we are certain from the frequency of reversions, or sporters, with decided yellow or white feathers from the same nests, or at least from the same parentage, which for several generations have been bred from pure birds.

At the last Crystal Palace Show there was a very evident exemplification of the effect of cross-breeding in the high-coloured Cinnamon class. Birds of a most beautiful colour and of splendid proportions very deservedly took the highest honours, although they gave strong evidence of not being of the purest caste. The characteristic features of the Norwich blood being very prominent at once suggested the source from whence their astonishing beauty had been derived. Whilst numbers of birds of the purest Cinnamon blood, most of them the property of one eminent breeder of the variety, gained only honourable mention. These last-named birds had been for years bred only from the finest selections of his own and other celebrated pure Cinnamon birds.

By crossing all varieties improve, but the direct progeny of such birds degenerate unless neutralised by judicious pairing: hence the difficulties so frequently encountered in our endeavours to secure excellence by breeding direct from a pair of purchased birds with whose descent we are unacquainted, and the necessity of breeding-up from our own stock at least one side of the parentage the properties of whose pedigree we well know.

Prizewinners have often been bred from judiciously crossed pairs, but it seldom happens that there are more than one or two such birds produced during the season by one breeder; but by selecting the more favourable specimens, and again pairing with pure blood, the strain is frequently much improved.

When pairing for excellence all properties must be duly considered, and where any advantageous peculiarity exists it must be assiduously cultivated. Excellence of the highest order can only be arrived at by continuous selection. Form, colour, quality of feathering—in fact all properties, are capable of cultivation, and may be more or less prominently developed by these means.

With regard to the Norwich variety—the one wherein colour is an indispensable qualification, how much has been done is very evident, irrespective of the new means of producing it by feeding. What can compare with the magnificent effect of a rich Buff specimen of this variety or a grand Jonque of the same family? They are repeatedly being staged at the Palace in the greatest excellence. Amateurs are continually purchasing such

birds for breeding purposes, yet how few new names appear in the prize lists! Why should this be the case? Because they continue to breed direct from the clear birds; and we may naturally conclude that the clears have arrived at the highest degree of perfection, which, should we continue to match clear with clear, produces colour in a diluted degree.

Colour is supposed to be derived directly from the Greens. Many old hands who have gained high honours in their time bear testimony to the fact, by stating it to be their belief if we should lose the Greens we should lose colour. As these rules have been carried out from the earliest times by great fanciers, it seems proved that to obtain colour we must not breed direct from clear birds, which at once justifies the correctness of selection and judicious crossing.

In pairing, Jonque should as a rule be matched with Buff birds. Where Jonque and Jonque are bred from, size is generally lost and an undesirable peculiarity of feathering produced. Where Buff and Buff are matched it is generally at the expense of colour but to the advantage of size, with an extraordinary exuberance of fine feathering.

On the other hand, we have a remarkable illustration of the consequences of consanguinity in pairing in the rapid degeneration of the variety known as the London Fancy Canary, once a favourite bird with all metropolitan breeders; at one time existing in goodly numbers, but now so nearly extinct that there are not more than from six to seven breeders in the kingdom, and possibly not one hundred representatives of the variety in actual existence. Unless some decided measures are taken at once to regenerate this beautiful but peculiar variety of the Canary it must ultimately cease to exist. There are but two or three breeders who have what may be considered robust representatives of this class, one a veteran of London, the other a gentleman amateur of Devonshire, to whom much credit is due for their steadfast perseverance to maintain the continuance of these birds. New blood to a limited extent has been infused into their strains.—J. Packham.

LONDON FANCY CANARIES.—No. 2.

A noted breeder relating to me his experience in Canary-breeding, once remarked, "Thirty years ago I first commenced breeding London Fancy Canaries. At that period there were established five Societies—viz., the Sovereign, the Royal, the Friendly, the Amateurs, and the Hand-in-Hand. The last-named Society carried on its business at a tavern known by the name of the 'Crown,' in Museum Street, Bloomsbury, Mr. D. Horne being the President. Other societies can be traced back for a century. The Hand-in-Hand Club came to grief somewhere about the year 1870. The chief aim of the members, as appears from the title page of the book of rules in my possession, was to improve the breed of Fancy Canary birds."

Before I proceed to remark upon the moulting process adopted by the members, I will give the characteristics of the two kinds known by the terms "Jonque" and "Mealy."

Colour appears to have been a great consideration. The Mealy birds should have their feathers fringed or edged with white, which feathers falling closely over a bloomy-coloured specimen shows to advantage that beautiful flowery or frosted appearance so much admired both by judges and fanciers. The Jonque birds should be the colour of a deep orange, with a silky quality of feathers. The black feathers in the flights and tail should be as bright as possible, but blackness of feather is considered more when colour is equal in two birds. The cap is the principal point; next breast, saddle, and back. Cap, saddle, and back will surpass breast, saddle, and back; cap and breast will beat saddle and back; but breast, saddle, and back will defeat cap, although the first point.

In a first-class show bird every feather in the flights and tail should be black in stalk or web, and not one entire white feather. Each flight should number eighteen feathers, and the tail twelve. The Hand-in-Hand regulations state, "No bird shall be considered a fair show bird that has a feather or feathers without black in stalk or web, in the flight or tail feathers, or that has less than eighteen flying feathers in each wing, and twelve in the tail."

In close judging it is often necessary to take the birds out of the cages to decide upon their respective merits, and this should never be attempted but by those who are qualified for their duties. There is an advantage in being what is termed or known in the fancy as a good "handler." Quality of feather is better decided upon with birds in the hands than when they are in cages. But a judge with a good eye may quickly use his power of discrimination, and settle matters which may appear somewhat doubtful to those lacking that advantage.

The following are the chief points by which the birds are judged:—

Cap—for colour, magnitude, and regularity.

Colour—for richness of yellow, not only in the cap, but throughout the bird.

Wings and Tail—black, home to the quills.

Size—for largeness and general elegance of shape.

**Pinions*—for magnitude and regularity.

**Swallow-throat*—for largeness.

**Fair breast*—regular.

**Legs*—blackness.

**Flue*—blackness.

Those points with an asterisk (*) prefixed, are specified as "additional beauties."—Geo. J. Barnesby.

PROPOSED SCHEDULE OF PRIZES FOR THE MANCHESTER BEE AND HONEY SHOW.

CLASS A.

1. For the best and largest results, or harvest, obtained from one stock of bees managed on any system, swarming or non-swarming, first prize, £4; second, £2; third, £1.

2. For the best and heaviest hive filled by a single swarm of 1875, first prize, £3; second, £2; third, £1.

3. For the best and heaviest second swarm, or turn-out, of 1875, first prize, £2; second, £1.

4. For best straw or wood super of honeycomb above 20 lbs., first prize, £2; second, £1.

5. For best glass super above 20 lbs., first prize, £2; second, £1.

6. For best straw or wood super above 10 lbs., first prize, £2; second, £1.

7. For best glass or wood super above 10 lbs., first prize, £2; second, £1.

8. For best glass super under 10 lbs., first prize, £1; second, 10*s*.

All the above to be the products of this year, filled in a natural way, and exhibited without bees, with their weights (gross and tare) ticketed on them.

9. For the best observatory or unicomb hive, first prize, £3; second, £2; third, £1.

10. For most ornamental hive—made of glass or glass and wood, first prize, £2; second, £1.

The above (9 and 10) to be exhibited with bees in them.

11. For best sample of 10 lbs. of run honey, 10*s*.

12. For best three cakes of wax, not less than 1 lb. each, 10*s*.

CLASS B.

13. For best bar-frame hive, £1.

14. For best straw hive, £1.

15. For best and largest collection of hives, bee furniture, and other necessaries for an apiary, first prize, £5; second, £2; third, £1.

16. For a collection of the best and cheapest supers (empty) for general use in an apiary, £1.

This schedule has been planned and written out with a view to make the bee and honey corner of the Exhibition at the Manchester Botanical Gardens next September as interesting as possible to visitors generally, and profitable and instructive to bee-keepers.

About £10 are offered for glass hives exhibited with bees in them, which generally please spectators. As the Show will last three days, arrangements will probably be made for the bees to fly abroad. If the weather be fine the bees flying about may smell the honey hives exposed to view. In such a case the bees would have to be confined to their hives, for it would not do to let visitors be startled and frightened by bees.

The schedule is, of course, subject to improvement or alteration. If more than £50 can be obtained by promise, more or larger prizes will be offered; and if any gentleman or number of gentlemen combined would like to see any question in apiculture fairly tested, and consent to give a prize for that object, we shall be glad to put it in the schedule.

At the Manchester exhibitions there are no entrance fees required, and the prizes are given at the close of the shows. Entries and inquiries will be received by Mr. Samuel Yates, 16, Old Millgate, Manchester, or myself, till the Friday before the opening day, which, I believe, is the 2nd of September.

All competitors and exhibitors will be permitted to sell their exhibits in the gardens.—A. Pettigrew, *Sale, Cheshire.*

LIGURIAN AND COMMON BEES.

I regret much that Mr. Bagshaw's challenge to test the working powers of Ligurian and common bees has not been accepted. Letters of inquiry as to the relative and comparative worth and merits of these bees are received from many persons, which letters are answered privately, to the effect that there exists no satisfactory evidence or proof that Ligurians either breed more or work better than common bees.

Some of my friends predicted that those who spoke loudest in praise of the Ligurians would be the last to come to the test of experiment; and so it appears, for one of your correspondents questions the wisdom of settling the matter, and thus removing all doubt, while he would have us believe without evidence that the Ligurians are superior. I have not his letter by me, but if my memory serves me well Mr. Hunter said, "If the Ligurians are better breeders, it follows that they will be better workers."

What does "if" indicate? It is that "if" we are seeking to remove.

I will here repeat that it has not been proven that Ligurians are better breeders than common bees, or better workers. They may be, but we have no evidence of it. I have seen, perhaps, the largest hive that was ever peopled by bees in this country filled with brood by common bees from side to side. There was as much brood in this hive as we can find in four or six ordinary-sized bar-framers, and this may be seen again and again. Where, then, is the evidence that common bees are not so good breeders as the other sort?

Our friends are "nonsuited," and will remain nonsuited till they produce a witness in court. We ask them to produce evidence, and encourage them to do so by assuring them that such evidence would gratify us and others very much.

I intimated last year that my own apiary would be converted into an experimental one, but owing to family affliction and other causes it has not yet been done. But I will here suggest a simple experiment to test whether the Ligurian queens lay more eggs than those of common bees. Let a swarm of each sort be put into a hive filled with empty combs for three or six days, and then count the eggs laid by each. Three such simple experiments would go far to settle the question, and it would give me pleasure to lend a helping hand by placing hives of empty combs and swarms at the call of those who may be willing to take the matter up. More I cannot do at present.—A. Pettigrew.

OUR LETTER BOX.

Chickens Dead in the Eggs (*C. Brown*).—As the hens sat steadily and were not allowed to be off too long, we have little doubt that the dryness of the wooden nest-boxes raised from the floor, rendered the shells too hard for the chickens to break. See what we say to another correspondent to-day.

Incubator (*R. P. G.*).—If we inserted your letter we must do similarly for others who have employed those of other makers. All incubators will hatch eggs in proportion to the careful management and other circumstances.

Sitting Nests—Perches (*Elstree*).—Sitting hens should sit on the ground. Chickens never come out so well and so strong as when a hen steals her nest. In that case it is always on the ground. Even where the hen sits in a box or basket which stands on the ground the bottom of the nest should also be a large sod of grass cut with plenty of earth to it. Bad perches will cause crooked breasts, but they are also indicative of weak constitution. Perches should be within 24 inches of the ground. A fir pole 14 inches in circumference sawn in half, placed with the round side uppermost, and with the bark left on, makes an excellent perch.

Sneezing in Fowls (*J. W.*).—We advise you to adhere to Brahmas. They are subject to none of these disorders. Your old birds will probably recover, at least partially, as soon as the east winds leave us; but we have no hope of the chickens growing up well if they too sneeze. Your present treatment will be to keep the birds scantily supplied with water, to feed on ground food, and if the unkind weather returns to mix some good strong beer with it. We presume your fowls are in confinement. If so they must be daily supplied with large sods of growing grass cut with plenty of earth. It is likely this may be a remanet from the roup; that would not alter the treatment.

Geese this Spring (*H. H. C.*).—Our experience is the reverse of yours We have never known the eggs produce better. Where the sexes are properly kept, and where gander and Geese have been used together, we do not believe in the failure of eggs. We know that a strange gander put down to Geese will not take to them directly, and the first eggs should not be set; but after an acquaintance is formed, if all the eggs fail either they are frosted or the Geese have eat badly.

Substitute for Canary Seed (*W. M. Grose*).—Canary fanciers have of late been put to their wit's ends as to finding a really good substitute for canary seed, owing to it being so enormously high in price. We have no hesitation in recommending millet seed as the very best substitute for canary; it can be used advantageously with hemp, rape, linseed, and groats. For several weeks past we have almost entirely discontinued the use of canary seed, and our birds never appeared in better health and condition. Our reason for so doing has been that we have not wished to encourage the extravagantly high price of canary seed. Millet seed partakes more of the properties of canary, being nourishing and warm. It is not an oleaginous seed, but possesses a starch-like property, and is suitable for supporting both bone and muscle. The white millet is the best for cage birds, being sweeter and more preferable than the yellow kind, which is more suitable for fowls. The Spice Birds, Java Sparrow, and other small foreign birds you name will thrive well on "two of millet and one of canary." A piece of salt about the size of a Spanish nut may be placed in the cage occasionally, whether your birds be well or unwell. The birds will not partake of more than will benefit them. The system requires a certain saline supply, which is requisite for keeping the blood in a proper healthy state; disease thereby is often checked. We recollect being once asked, "What is the size of a lump of chalk?" Our idea was that it meant a large piece. By the same rule we may suppose that a "lump of salt" means a large piece. In our remarks upon "Canary wheezing," p. 288, we believe we advised the necessity of putting inside the cage a "small piece of salt" to supersede the sugar (lump of course), therefore we are not sure that a lump of salt would be needed by your birds.

Java Sparrows (*M. H. F.*).—We have always had a great fancy for these very beautiful close-feathered cage birds, but we never put up a pair for breeding purposes. If you intend so doing, supply them with white millet seed and a little egg and biscuit mixed, in addition to their usual rice and canary seed.

Bees Killed by Cold (*C. H.*).—The bees you found with pollen on their legs beneath the flight-board were chilled and benumbed by cold. Those forwarded for examination appear to be young bees, chilled and killed on making their first attempt to work. We have found many such chilled into a motionless state on the flight-board, and therefore quite unable to crawl into their hives. Young bees, like young chickens, cannot bear much cold. If bees simply chilled and motionless, be placed in a warm place their powers will speedily be restored.

Bar-framed Hives (*F. J., Cork*).—You cannot do better than order one of Abbot's "new frame bar-hives," which are really marvels of cheapness and excellence of workmanship. The cost of hive complete with roof, reversible floor-board, and two Crystal Palace prize supers, can be had of Mr. James Lee, Bagshot, for £1 17s. 6d., but you can have a still cheaper hive on the same principle, of Mr. Abbott, Hanwell, W., for 6s. 6d. We have both these hives and can hardly imagine anything better. Common English bees are very good indeed. Doctors differ as to whether they or the beautiful Italian bees are superior in point of honey-gathering powers. Fifteen shillings is not too much to pay for a thoroughbred Italian (or Ligurian) queen.

Bees in Common Hives (*B. L. B.*).—Let your bees swarm naturally, and put the swarms into the hives you wish them to fill. Probably they will swarm twice, but if they swarm once only you may fill another hive by driving all the bees out of the old hive into it three weeks after the first swarm shall be had. Thus two good swarms will be obtained, and the honey from the old stock. If a second come off naturally you will have bees to put into your three new hives; but do not attempt to divide a swarm with a view to multiply your stocks. Neither can a stock be created by placing a bit of broodcomb in an empty hive without a swarm. Brood requires both warmth, and food, and will perish in the absence of bees to impart them.

REMARKS.

14th.—White frost early; then bright till 9 A.M., when it came over very dark, and so continued until 11 A.M.; bright and fine afterwards.

15th.—Fine morning; day rather dull at times.

16th.—Cloudy morning, but fine pleasant day.

17th.—White frost; misty early; bright warm day; misty evening.

18th.—Cold in early morning, with traces of frost; beautifully fine day.

19th.—Warm and bright throughout the day. Air very dry, as the following figures prove:—

	Dry ther.	Wet ther.	Difference.	Dew point.	Humidity. 0.100
	°	°	°	°	
9 A.M. ..	54.2 ..	48.1 ..	6.1 ..	42.1 ..	64

20th.—Air not so dry, nor so clear; sun temperature lower; and in the evening air quite thick; clearer at night.

A very fine and absolutely rainless week.—G. J. Symons.

COVENT GARDEN MARKET.—April 21.

A slight improvement in trade has taken place, rough goods being in very fair request. Continental supplies are much favoured by the present weather, and comprise Asparagus, Beans, frame Potatoes, Artichokes, young Carrots, Turnips, the usual varieties of Cos and Cabbage Lettuces, Endives, and Green Peas.

From observations taken near London during forty-three years, the average day temperature of the week is 61.9°; and its night temperature 37.5°.

EFFECTS OF THE EAST AND NORTH-EAST WINDS.

IT may appear something like horticultural treason to say anything in favour of the parching east wind of whose pernicious effects couplets, based on the experience of past ages, have long ago vented a meed of abuse very much approaching a curse, and compilers of almanacs have added their quota of dislike to the drying currents of air coming from that quarter. Yet somehow, like most other evils, the east wind is not altogether devoid of some useful qualities, and although it may not be good for either man or beast, as the distich goes, it exercises a beneficial influence on what both man and beast depend on for supplying their wants.

"Mother earth," especially when under an artificial course of management, derives considerable advantage from the unpleasant east wind; and for road-making it far exceeds Macadam or the other great authorities whose opinion in that way is so much acted upon. But it is only in the limited arena of artificial works that road-making by mechanical means is resorted to, and useful as that area is, it bears but a small proportion to the extent of surface which the east wind and its kindred one from the north-east operates so advantageously upon for all the purposes of easy and agreeable locomotion. In other words, the drying wind we have from that direction, licking up, as it does, every semblance of moisture, prepares the ground to receive any reasonable amount of weight upon it, which it could not bear without injury when in a wet state. So much, then, for the uses of the east wind in that respect.

Let us now see how it affects the husbandman, or rather the tillage land which he has to deal with, as well as the various squares and plots in the kitchen garden that may be more or less under its influence, and not forget the fashionable flower beds which at this season may be still more immediately within the scope of its operation. These and all other plots of cultivated ground so evidently benefit by the drying influence of this so-called nasty east wind, that we are constrained almost against ourselves to say something in its favour, notwithstanding the many diseases and discomforts it is blamed for bringing in its train. But as these matters have their exponents elsewhere, let us see how it acts as a fertilising agent, and a very slight survey will enable us to see that its influences tell to great advantage in the preparing of the soil for the various crops that may be put upon it. By its being the means of abstracting a great deal of the superfluous moisture by which the soil is saturated, and by penetrating itself, the hitherto soddened ground becomes to a great degree aërated, and in due time falls in a mellow form to the touch, and consequently all its component parts become available to the action of the roots of plants that may be planted upon it. In this respect the east winds of a dry March in some degree exercise the same fertilising mellowing powers that a hot dry summer does on lands that may be fallow at the time, the air being enabled to penetrate where the moisture had been withdrawn, and hence the beneficial effects of the otherwise uninviting east and north-east winds. In an usual way we are visited with easterly winds for a considerable time every spring at a period when the soil requires drying, and the presence of the wind is hailed as the commencement of a new state of things, and the drying effects of it are very acceptable.

Of the causes which render the east wind so pernicious in some respects it is not our purpose to inquire. Suffice it to say that in this immediate neighbourhood the number of days in which it blows from that direction is fewer than any of the other seven directions into which the compass is roughly divided. By taking the observation at noon each day I find the yearly average of days for plain east is about seventeen, while that of north-east is sixty-two; this being for a period of twenty-five years, the average may be regarded as a fair one. The south-west wind is the most prevalent, as well as generally the highest; while that from the north-east is deprived of much of its withering influences when it visits us in August and September, as it seems to have all the softness of that from a contrary direction, and vegetation is not a sufferer from it, further than that it is often attended by prolonged dry weather, and rain is hopelessly wished for during the time; nevertheless we now and then have very heavy rain with the wind in that quarter, the popular notion being that if we have rain at all with a north-east wind we are likely to have a good deal of it, and it often is so. On more than one occasion we have had considerably over an inch of rain within the twenty-four hours with a north-easter.

This is more especially likely to be the case in summer; in March a dry, chilly, cold atmosphere is more generally prevalent, which is good for the land that is in tillage, as has been explained, but not by any means agreeable to newly-planted plants, be they small herbaceous plants or evergreen shrubs; in fact, I am not sure if May be not a better month for the removal of the latter than March, as, a more genial atmosphere and a more quick root-action following, the plants do not suffer by the delay in waiting for a suitable season in which to repair the damages done to the roots, &c., by the removal. Nevertheless March is often of necessity an important planting month, trees and shrubs are not always ready before, and in the case of deciduous trees it answers very well if the operation be well done and the soil is in a fit state to receive the plants.

But all soil operated upon is not in a fit state; even that which is in tillage may have been turned up in wet weather, and its component parts may have been unduly trod upon and compressed when in a wet state, and hard, unkind, ugly lumps be the result, the lumps resembling in some degree sun-dried bricks, and if the planting has to be done before these yield to the mellowing influences of the wind alluded to, success is very uncertain. Where of necessity work must be done and crops put in while the soil is in this condition, they ought to receive

due attention afterwards. I am not certain but waiting awhile would be quite as well, only the usual abundance of work that crowds upon us at this season necessitates planting to be done when it can, and the cold winds have to bear the blame for the want of success which might have been different if sufficient time had been allowed for them to have done their beneficial duty towards our tillage lands.

There are other useful objects attained by these much-abused east and north-east winds; if they do chap our lips and hands, and cause many other discomforts, they benefit the general atmosphere in a sanitary point of view by removing or mitigating smells or other impurities, and thereby doing much to compensate for the bad name we have unthinkingly attached to them. And notwithstanding the delay they cause to vegetation and being blamed for late springs, we are not sure but these very delays are beneficial; and when a change does take place after the cold period everything seems to revel in it, and most likely the more so from its being withheld longer than expected.

Let us, therefore, not too hastily condemn the winds from the quarter alluded to, but justly reflect that, like many other so-mistaken evils, they all tend to a good purpose.—J. Robson.

THE SETTING OF FRUIT BLOSSOMS.

"Dewing the blossoms over with clear water from a syringe on the morning of a fine day is a good way to scatter the pollen and to promote fertilisation." Thus has Mr. Douglas written in his useful "Doings" on page 299. That is advice which is diametrically opposed to the settled notions of the great majority of gardeners, whose principal aim in the fruit-setting period is to have the atmosphere of their houses as dry as possible, and who would regard the wetting of the blossoms as an unpardonable blunder on the part of any assistant who should unfortunately commit such a great mistake. Yet for all that I am one who fully believes that Mr. Douglas never penned more sound advice or detailed any "doing" more likely to effect its purpose. The work, however, should be done exactly at the time and precisely in the manner stated. It should be dewing, not washing, and on the morning of a bright day, not of a dull one. In a word, the work must be intelligently performed, and it will prove a valuable auxiliary in the setting of fruit blossoms under glass, and also on south walls. The practice, however much one may be convinced of its efficacy, is of a nature to demand some moral courage to recommend. First, because it is antagonistic to generally recognised theories; and secondly, lest it should be overdone, or be done at the wrong time, and the blame be cast on the advice itself instead of on the bungling way in which it has been carried out.

Now, it may be taken as a fact that shoals of fruit blossom fall to the ground to the no small anxiety of the cultivator, and for which he can assign no satisfactory reason. Very frequently the blossom-shedding is a benefit to the trees, but often the fall is so extreme as to leave but little fruit behind for a crop. That happens both on the trellis under glass and on walls in the open air. When under glass the cause is generally sought for in overdryness of the soil, and in fact that is, despite all the advice given on the point, a great source of the premature dropping of fruit blossoms. But it can hardly be from overdryness of the soil when the blossoms drop from trees in the open air. There may have been no frost to account for it, or if there had the trees have been covered. It is, in fact, often from trees which have been covered during the night that the blossom falls the most extensively. This fact has led many people to lose faith in coverings, and instances have been by no means rare where an uncovered tree has carried a more satisfactory crop of fruit than has the one by its side which had been covered. It is because of that—covered trees failing to carry crops of fruit—that some people never protect their trees at all. Occasionally they pay the penalty of their temerity by having their blossoms frozen, but frequently they can point triumphantly to their crops when their neighbours who had protected their trees are grieving under a scarcity of fruit.

That blossoms are injured by frost is certain, and not much less certain is it that they are injured by a lack of moisture, as, for instance, the absence of dew. No doubt extreme wet is pernicious to the blossoms, and so also, but not so generally recognised, is extreme dryness to the embryo fruit. Under what conditions do blossoms on wall and orchard trees set the best? Is it during a period of brilliant days and dewless nights? No; blossom generally falls then. It is during mild weather with sun, yet with light spring showers occasionally falling, that blossoms are followed by fruit, and the trees become laden with produce. Why is this so? Note the blossom of a fruit tree at a period when dewless nights are followed by brilliant days. The petals lack substance, and are flimsy and crumpled; touch them and they fall. Examine them in more genial weather, when the sun is sufficient to dry them and the night dews and occasional showers are provided to refresh them. The petals are then much stouter in texture, and the blossom is more lasting; touch it and it is fast. That is the condition by which you may expect fruit.

Has it not been noticed that Apricot trees have in some years set their blossoms on a west better than they have on a south aspect? When such is the case the setting season has been remarkable for an arid air and unclouded sun. The blossoms and the embryo fruit could not sustain the transpiration they were called on to bear, and collapsed by sheer inanition. Their vitality was fairly extracted from them under the influence of the moisture-absorbing sun. That is especially the case with trees that are deficient in vigour, and which, as a consequence, are often excessively laden with blossom. These blossoms, weak to begin with, are almost certain to succumb if the air is exceptionally dry and the weather excessively bright during the time the trees are in bloom; whereas if they have the assistance of moisture to sustain them, and the young fruit have no check in being robbed of support during the process of setting, a pleasant sprinkling of fruit will follow.

Under an extremely bright and dry-setting season the shady side of a tree will often set the fruit, while on the sunny side the blossoms fall to the ground. Under those circumstances we generally attribute it to frosts which have come from the south. But it is the sun and not the frosts that have levelled the blossoms to the ground. I have in hot weather, and with weakly Apricot trees, had one tree laden with fruit, and the next barren, by simply dewing the blossoms of one with a syringe, and affording support to the embryo fruit at a critical juncture. I have had even, for the purposes of experiment, one side of a tree fruitful and the other side fruitless by the same means. I have seen a trellis completely wreathed with Peach blossom, which by a sharp shake during a brilliant setting period has fallen off by thousands, except a portion which has been dewed or even shaded for an hour or two, and this covered with fruit. I have seen Vines in blossom treated to a highly dry temperature, and the set of fruit of a most unsatisfactory kind, but have never had or seen any difficulty in setting Grapes when a healthy degree of moisture has been intelligently imparted to the atmosphere.

But there must be no mistake; extreme moisture is also inimical to the setting of fruit blossom. The pollen must be sufficiently dry for distribution, and must be distributed. That is what is required, and all that is required; and then a measure of moisture becomes as much a necessity to support the fruit as is, or was, the requisite degree of dryness to move the pollen. There are times when the blossoms of fruit trees are kept too dry—when the sun is powerful and the night dews prevented doing their restorative work. That is seen when covered trees are less fruitful than those which have been exposed.

The same law applies under glass. We may keep the air too dry, and permit the blossom to be played on by a burning sun, when the embryo fruit are gasping for want of a little moisture. But, as said before, this must be given carefully and at the right time. In preventing the roasting of the blossom let there be no drowning; but yet it is well to recognise that, however little the matter is thought about, that the blossoms of fruit trees can be shrivelled by drought and heat, and the embryo fruit be literally roasted on the trees, and then we wonder why the blossoms fall.

I conclude by asking that the quotation from Mr. Douglas be read again and thought about, feeling sure that it is sound and full of truth.—A Surrey Gardener.

ROSE FELIX GENERO.

In reply to "Cornubia" of March 25th, page 230, Rose Felix Genero I consider a good one for exhibition. I placed it with last year's election of fifty, and have shown it remarkably fine at South Kensington, Birmingham, and elsewhere last year, and also in 1873. On half-standards it does well. Prince Camille de Rohan, as Mr. Radclyffe states on page 292, was omitted by me in last year's election. I find it useless

with me as an exhibition Rose. I consider the last year's election of fifty Roses a good guide for amateurs.—J. Mayo, *Oxford.*

THE ROYAL HORTICULTURAL SOCIETY'S FLOWER SHOWS.

As one of the exhibitors I may be allowed to make a few remarks on the present aspect of affairs. The two spring shows have been held—the Hyacinth Show in March, at which prizes to the amount of £126 6*s.* were offered, but so few exhibitors came forward to claim them that the total amount awarded, less, of course, the 50 per cent. reduction, was only £12 12*s.* 6*d.* For April 21st a very good list of prizes were offered for Rhododendrons, Azaleas, Cinerarias, Auriculas, Grapes, Strawberries, and forced vegetables—in all, twenty-three classes. The number of competitors was but nine, and the amount of money awarded was exactly £8 7*s.* 6*d.* This is an amount of hard cash saved to the Society sufficient to satisfy the most rigid economist—twenty guineas in prizes for the two large Spring Exhibitions! Well might Fellows of the Society wander from one arcade to another inquiring for the Show, and when they did unfortunately discover the few plants, no wonder they turned away in disgust.

Now I think not only the Fellows but exhibitors also have a right to ask who is responsible for this state of things. Where does the blame rest, with the exhibitors or the Council? Now, I cannot see that any part of the blame can be attached to the exhibitors. After the schedule had been issued in December the Council discovered that the expenses must be curtailed, and after some consideration they, without consulting the exhibitors, determined to reduce the number of shows, and to adhere to the scale of prizes advertised in the schedule. The next arrangement was that the shows would all be held, but that 50 per cent. would be deducted from all the prizes awarded. It was stated that the Council had on this occasion consulted the exhibitors, especially the exhibitors of florist flowers. Well, it would be worth while to ask the Council—Who were consulted in this important matter? Mr. James Cutbush of Highgate has already told us he was not, nor were the Auricula growers as represented by Mr. C. Turner, Mr. James, Rev. H. H. Dombrain, and Mr. Douglas. The Council ought to be aware that many of the best amateur exhibitors are not members of any of the Committees, and when such an important alteration is contemplated as reducing the prizes by one-half, all the exhibitors ought to have been consulted. I have no doubt if the Council had issued circulars to the exhibitors inviting them to attend a meeting, and had in a straightforward manner stated the position they were in, they would in a body have rallied round the Council, and the shows of 1875 would have been quite as successful as any ever held by the Society.

What is the effect of the blundering management of the horticultural party on the Council? Simply this, that neither the trade nor amateur exhibitors have any confidence in them. They say the exhibitors had been consulted, and that it was in deference to them that the revised alterations were made, when it is notorious that the exhibitors as a body knew nothing about it. If the Council thought that they could reduce the prizes, or reduce the number of shows within a few days of the dates they were advertised to be held, without having the courtesy to consult the exhibitors about it, the miserable failures of the recent exhibitions must have woefully undeceived them. The fact is the Council is making the Royal Horticultural Society the laughing-stock of all the practical horticulturists of Britain. It is quite evident that they do not understand the purposes for which the Society is maintained, and the time has now come for something to be done by the horticulturists themselves. There are a certain number of Fellows who pay their money for the pleasure they derive from using the gardens as a recreative ground. By all means let them have it; but it is too bad that the funds derived from those who are subscribers because they hope to benefit the cause of practical and scientific horticulture should be spent on the flower beds and grass terraces of the South Kensington Gardens.

The horticultural party ought to leave the Society to its fate, and form a society of their own. They are quite strong enough to do so. If the Defence Committee is still in existence it ought to meet. There is quite as much necessity now as ever there was. They ought to take some definite proposals to the Council, and if the Council will not co-operate with them, they ought to be prepared to carry them out themselves. In all the large provincial towns horticulture is flourishing. In London, which ought to be far in advance of any of them, exhibitions are at a discount. It ought not to be so, nor would it if those who ought to be leaders would take up their rightful position.

Let us hope that as matters are now at the very worst there will be a change for the better. The Fruit and Floral Committees are doing an important work, and the meetings should not be interfered with. The expense of the meetings to the Society is as nothing compared to the benefits which the country derives from them; but the number of shows may very well be reduced. There ought to be a show for Hyacinths and other spring flowers about the middle of March; the next about the last week in April for Auriculas, Cinerarias, Azaleas, forced Rhododendrons, pot Roses, &c.; then the great summer show; an autumn show for Dahlias, Gladiolus, Hollyhocks, Asters, Liliums, &c.; to conclude with a show of Chrysanthemums and fruit in November. Of course the Rose show ought not to be omitted in July, but five, or at most six, shows would be a sufficient number. However, it is no use proposing anything until the Council and exhibitors can work in harmony together.—An Old Exhibitor.

THE ORCHID-HUNTER IN BURMAH.—No. 4.

The next Orchid especially abundant in Pegu is Phalænopsis cornu-cervi. This plant is met with occasionally in Moulmein, but in no part of Burmah does it grow in such quantities as in the Pegu district. It is found on trees surrounding swamps and on solitary shady trees in the forest, and is one of the few Orchids invariably found in the shade. Its leaves and roots are very succulent, making it a bad plant to bring in from the jungle, it being so tender and liable to damage; it is one of the most curious and interesting of the genus Phalænopsis. It derives its characteristic name, cornu-cervi, from the form of the flower stalk, and is commonly called the Stag's-horn Phalænopsis. This stalk invariably grows in the shape of a stag's horn, and the flowers grow out from each of the joints. It flowers very freely, bears enormously large seed pods, and is one of the few sorts of Phalænopsis which strike out young plants from the old flower stalk. The flowers are yellow tinged with green, with straight bars of brownish red across the petals. It is a very easy plant to cultivate, large plants commencing to flower directly they are established. It grows best in a teak-wood basket with broken crocks and moss, and likes the shadiest place in the Orchid house.

This plant should always be sent home by collectors in February. It is then in its driest condition and best fitted for travelling. Special care at this time of year must, of course, be taken in the packing so as to prevent injury from frost on arrival in England. If importers could procure their plants under these conditions there would be no failures, and it would be more common than it is at present, and from its great singularity of character and from the distinctness of its form it would be in great favour with the general cultivator.

Phalænopsis Parishii, the one named after the Rev. Mr. Parish, the great authority on Moulmein Orchids, is also found here growing under the same circumstances as Phalænopsis cornu-cervi. It is a pretty little plant bearing white and purple flowers, and is deciduous like Phalænopsis Lowii, and equally difficult to cultivate. It grows better on a piece of wood than in a basket.

In the open country, on smooth-barked trees, growing in single plants, not in a mass like other Saccolabiums, is found Saccolabium ampullaceum. It bears a number of spikes of very pretty pink flowers, sometimes in good plants quite masses of rosy pink blossoms. It likes plenty of air and light, and is never found in any but the most exposed situations. Its leaves are opposite, short, thick, and blunt, green, generally covered with brown spots on both surfaces. It is from the axil of the leaves that the flowers burst so freely. Growing in great quantities, quite covering the trees in many cases in this district, is found Saccolabium bigibbum, foliage bright green, short, thick, and premorse-flowered, yellowish, a most profuse bloomer, and always found in situations fully exposed to the full influence of the sun. It may be observed of this as of most kindred plants growing under the same circumstances, that the trees they grow on are located in low-lying valleys and swamps where the mists hang in the morning; so that even in the driest weather the plants receive some

nourishment to enable them to withstand the rays of a tropical sun.

In the open country on the trees skirting the fields of Rice luxuriates Saccolabium Blumei. It is no exaggeration to say that this plant is found in thousands. It is quite beautiful to see a tree covered with this epiphyte in flower. It generally flowers during the first break in the rains about July. It is so very well known to all horticulturists that it is unnecessary to enlarge on the form of its flowers, which are white spotted with rosy purple borne on a long raceme. This plant is rare in the forests, which it appears to have forsaken for comparatively civilised haunts, and it is never found in such luxuriance as on the trees by the Rice fields. An explanation of the luxuriance of its growth under these circumstances is very easy. Rice is grown in water, the ground on which it grows being irrigated, so that the ground is under water nearly the whole year, the water being only withdrawn from the fields just before harvest. Thus the epiphytes growing on the trees surrounding the paddy fields are always deriving nourishment from the evaporation continually taking place, and an extraordinary luxuriance of growth is caused by this circumstance.

Aërides Lobbii is found in this district pretty freely scattered. It is, as a rule, found in the forest in less exposed situations than other allied species. It is a charming plant, and grows after the manner of its Indian ally Aërides Fieldingi, bearing long racemes of flowers, very light pink, spotted with dark pink, the labellum being quite pink and of pointed form. In fine plants the flower-stems have a branching habit, throwing-out spikes of flowers along the main flower-stem, which gives it a most graceful appearance.

There are many small Orchids botanically interesting, common to the plains of Pegu, but of little interest to the horticulturist; one of these must, however, be excepted—Luisia Psyche. This plant, unlike all other forms of the genus Luisia, bears the most charming flowers. The plant is epiphytal caulescent, growing perfectly erect, with terete rigid leaves, bearing in their axis its beautiful flowers, light yellow, with fine rich purple labellum of velvety texture.

This is undoubtedly the most remarkable of all the Burmese Orchids. The flower looks more like an insect than a blossom, and the form of the labellum is most striking. Luisia Psyche is easy of culture, growing well on a block. It is accustomed in its natural habitat to the full blaze of a tropical sun, and is found on trees growing on dry ground, where no other Orchids, except its allies, are found growing.—E. S. B.

ROYAL BOTANIC SOCIETY.

The second show of the season was held yesterday, the weather being genial and pleasant both for plants and visitors. The exhibition was a very good and attractive one—indeed, the best metropolitan display of the year. We are only enabled to give a cursory review, omitting the awards, which were not completed when we had to leave the corridor.

In the class for twelve stove and greenhouse plants Mr. Ward, gardener to F. P. Wilkins, Esq., and Mr. Wheeler, gardener to Sir F. H. Goldsmid, Bart., both staged excellent collections.

For twelve Rhododendrons (nurserymen), Messrs. H. Lane and Son had excellently-bloomed large plants, Mr. Cutbush staging small compact plants in good condition.

For nine Roses (nurserymen), Mr. C. Turner staged really fine examples, also a good miscellaneous collection. In the class for six Heaths compact and healthy plants were staged by Mr. Wheeler and Mr. Ward.

For six Azaleas (nurserymen), Mr. C. Turner had splendid large plants; Messrs. Cutbush & Son small but healthy plants. Messrs. H. Lane & Son and Dobson & Sons also exhibited good collections. In the corresponding class for amateurs Mr. G. Wheeler, gardener to Sir F. H. Goldsmid, had massively bloomed specimens. Mr. James also contributed nice plants.

For nine Cinerarias Mr. James and Messrs. Dobson & Son staged good collections. The class for hardy plants was occupied by a beautiful lot from Mr. Parker, Tooting, and Mr. Wheeler.

In the class for six stove and greenhouse plants (Orchids excluded), Mr. Ward and Mr. Wheeler staged effective groups.

For six pots of Mignonette, Mr. Barnes staged beautiful pyramids. Mr. Toms also competed. Mr. Harborough staged a gay collection of Amaryllis.

Amongst new plants Mr. Bull exhibited remarkable plants of Typhonium Brownii, Amorphophallus campanulatus, Dracontium asperum, and several Dracænas. Messrs. E. G. Henderson sent Pelargoniums Happy Thoughts, Distinction, and Comte de Gomer, Daisies, Pansies, Primulas, &c., also standard plants of the beautiful Lithospermum fruticosum, and double Cinerarias.

Mr. Turner exhibited a hybrid Rhododendron, Countess of Dudley, a beautiful white sweet-scented variety of great excellence. Hybrid Azaleas from Mr. Carmichael were effective; Royalty being very fine, and Mr. and Mrs. Carmichael, of the Amœna type, distinct and good.

For the prizes offered by the Metropolitan Floral Society for Auriculas there was a gratifying response, the Rev. H. H. Dombrain, Mr. Douglas, Mr. Turner, and Mr. James staging plants bright, fresh, and beautiful, many of them possessing high merit—creditable to the cultivators and encouraging to the Society. Mr. Turner and Mr. Douglas also staged good miscellaneous collections. Mr. Douglas also sent a splendid basket of finely-grown Primula cortusoides amœna.

Cut Roses were sent by Mr. W. Paul, and a basket of plants of the beautiful globular Rose Peach Blossom. The cut Roses also from Mr. Walker, Thame, were very superior. Messrs. Carter & Co. exhibited their new Coleus Duchess of Edinburgh—a distinct and beautiful variety. The same firm sent variegated Musk; and Mr. Hooper, Bath, a box of very good Pansies.

Messrs. Veitch & Son, Mr. B. S. Williams, Mr. Bull, and Messrs. Cutbush & Son staged highly attractive miscellaneous groups of plants.

BEDDING GERANIUMS.

I can quite confirm what is said by "C. P. P." on page 289 as to the secondary place Mrs. Pollock must now occupy amongst Golden Tricolors for bedding purposes. I find Sophia Cusack, Sophia Dumaresque, Lady Cullum, Sir R. Napier, and William Sanday all superior to Mrs. Pollock, being equal in growth, but more bright and lasting in colour. As Silver Tricolors I find Italia Unita and Charming Bride admirable for bedding in an exposed situation.

I do not recollect ever seeing any mention of Souvenir de Sir J. Paxton as a pink-flowering bedding variety. I find it very superior, being of good colour, free yet short growth, stout in the stalk, and its trusses lasting in perfection a long time. I believe it was raised at the Crystal Palace by Mr. Gordon.—J. Rogers, *Langton Hall.*

AQUILEGIA GLANDULOSA.

This beautiful Columbine is a plant which only requires to be once seen in something like perfection in order to be ever afterwards regarded as one of the finest hardy herbaceous plants we have. Why it is not more generally grown is probably owing to the fact that it is regarded as being more difficult to cultivate than it really is. In heavy clayey soils it will not grow, nor will it survive the winter in damp low-lying situations, even though the soil be of a lighter description. In such places it must be treated as an alpine plant, and be grown either on a rockery or in a prepared border; and what it seems best to thrive in is a mixture of sandy loam and peat, in which it grows almost as freely as any of the genus. The sepals of the flowers are of a deep bright blue, and the petals of a light cream colour; and a well-grown plant bearing a profusion of flowers, which are usually from 1½ to 2 inches in diameter, is an object not easily passed by.

There is a variety which was sent out many years ago by Mr. Grigor of Forres, the well-known writer on arboriculture. It is more robust, larger in all its parts, the flowers sometimes measuring as much as 4 inches across, and the petals nearly pure white with a blue spot near the bottom of each.

The best mode of propagation is by seeds, which should be sown whenever they are ripe; and though few if any of the seedlings will come up before the following spring, most of them will then do so.—R. D. Taylor.

PEARS.

Having given much attention to the cultivation of Pears, and having tried every system of growth and training, on Quince and free stock, pyramid, espalier, and cordon oblique, I entirely endorse the opinion of Mr. Lea as to the capriciousness, uncertainty, and variableness of almost every variety of this fruit. Like him I fruit annually sixty varieties (indeed, nearer seventy), and find those sorts named by him in the Journal of the 15th keep the best, though many years Knight's Monarch may be added to these; and as late cooking Pears, Léon le Clerc de Laval and Beurré de Printemps.

Mr. Lea says he "cannot find Fondante du Comice on any list." He may see it in the catalogue of Monsieur Dauvesse of Orleans of the year 1865. I have no later. It is there described as first quality, ripe in October. He will also see Fondante des Charneuses, a Pear there called "*de toute premiere*

qualité." I have grown it for some years on Quince against a south wall, but it has never been more than second-rate with me, and I should never assign it a high place in my collection, for I find it vastly inferior to Beurré Superfin, Beurré Lucratif, and Doyenné Boussoch as an autumn Pear. Your correspondent does not say when it ripens with him or whether it keeps. In France it is ripe usually the latter end of October, with me a little later.—H. S. S.

CONVOLVULUS MAJOR.

This Convolvulus, or Morning Glory, represents a family of beautiful summer-flowering plants, and has long been popular as a garden twiner; yet it is not cultivated nearly so extensively as formerly, being omitted from sundry gardens which it once so well adorned. Plants of dwarfer growth and compact habit have of late years received the lion's share of attention by floral caterers, while many an old garden favourite has almost been denied official recognition. A plant like this can, however, always hold its head above mere fashion, and will cling to British homes from generation to generation. It will, too, always find friends to welcome it, not because it will "go" well with something else, or that it is adapted to any particular style of the times, but because of its inherent grace and intrinsic beauty. For variety of colours, their extreme richness and refined delicacy, as well as the fine bold shape of its flowers, the friends of our childhood—the climbing Convolvulus, yields in real attractiveness to few summer-blooming garden plants.

Fig. 81.—Convolvulus major.

The popular name, Morning Glory, is very expressive, the splendid flowers unfolding their beauties to the first rays of the sun, and as then seen, with the dew glistening on their polished surface, they are, indeed, at that time a glory of the garden. Their beauty is, however, not lasting, as the blooms close against the fiercer rays of mid-day splendour and the appositeness of the name becomes more distinct.

But these fine blooms are not only the glory of the garden, but are also the glory of the breakfast table. Fresh gatherings every morning loosely grouped in vases are a charming accessory to the first family gathering, and will add an additional ray of cheerfulness to the cheery morning meal. The contrast of colour with the spotless linen ground, the classical shape of their flowers, and their striking individual beauty combine to render their grouping highly attractive, and for this particular purpose no flowers can surpass them. And how beautiful they are in the garden for training up string by walls, for covering trellis work, for forming floral arcades and festooning, to pile up in bold pyramids formed of string or stakes, for balcony trailers, and for window-box culture, to be fringed round the windows! In all these forms they are most ornamental, and to which they are specially adapted.

These reminders are necessary, for we would not have these common flowers forgotten, or their adaptability to such modes of ornamentation overlooked. Their possession is, furthermore, of the simplest, the only outlay required being for a packet of seed; and their culture is of the easiest, as they only require deep rich soil and a liberal supply of water to grow them to perfection.

But must not the seed be raised in pots, and the plants be hardened-off and planted-out? That is a very natural question which may arise after reading instructions on the point. The reply is the instructions are right, but they need in no way deter those who have neither pots or glass from having Convolvuluses. Plants may be prepared in that way by those who have the means, but much greater harm than good is generally done by the adoption of that practice. They are grown under glass and are drawn, they are put out and are checked, the sun burns the delicate leaders, the snails do the rest, and the growing of Convolvuluses is given up. No plants require nicer care in preparing under glass than these, and it is only when the work is intelligently done that success follows.

The old plan, and it is a safe one, is to sow them outdoors, if possible where they are intended to bloom. This must not be done early. The young plants are tender, and must have no checks by cold. Consider them as French Beans, and keep the seed in the papers until the soil and the weather is warm. The last days of April or the first week in May is the time to sow the seed.

A free, quick, unchecked growth at the beginning is the main point to aim at. To secure this let the surface-soil be rich and light; 6 inches of pure leaf mould is the best of all mediums in which to sow the seed. The plants in that grow quickly, and yet are strong. Beneath the leaf mould must be a good depth of richer soil to afford the necessary sustenance. This and copious waterings in hot weather will carry the plants to perfection. With this simple care it is surprising how rapidly the plants grow. Seed sown in May in these prepared sites will soon leave the plants behind which had been sown early and coddled under glass previously to being planted-out. When sown in a bed of leaf mould young plants may be removed from one part of the garden to another when they are 2 or 3 inches high. They must be preserved from slugs.—W.

RHUBARB CULTURE.

Seeing the reply to J. Heed's question about Rhubarb, I may mention that I have a variety which we always call Peach Rhubarb, owing to its having a distinct flavour of ripe Peaches when cooked. I do not know what the real name of it may be. It is a strong-growing late sort, and when forced in the dark has creamy white stalks spotted with pink: it is only in this condition that it retains its fruity flavour. If grown in the open air and allowed to become green it tastes pretty much like ordinary Rhubarb; and this reminds me how few there are who make the most of this delicious fruit-vegetable.

Everyone cannot have Grapes and Peaches in winter nor fruit tarts in spring and summer, but all who have a few yards of ground can obtain that which is, when properly managed,

a delicious substitute for them. At Christmas, when Apples have become scarce and tasteless—when hothouse fruit is only obtainable by a few—when Currant, Gooseberry, and Raspberry bushes are bare—it is no slight blessing to be provided with an easily cultivated vegetable which to a certain extent supplies their places and is within the reach of almost all. How fresh and tempting the bright crimson stalks of Rhubarb look! and how refreshing and grateful is its pleasant acid flavour! At that season of the year I confess I have a special weakness for it, a weakness which appears to be shared by all my family, even by the children, for children as a rule do not like Rhubarb; I suppose it is because few of them have it at the proper time, or if they do it is not properly grown, and not used while fresh and crisp. I remember when I was a boy at school the intense disgust with which I used to herald the arrival of the great heavy-crusted green Rhubarb pies in early summer—for we rarely saw them before the late outdoor sorts had come in—stringy, and tough, and sour as vinegar. This is not the time nor the way to have Rhubarb: in this state it competes very disadvantageously with green Gooseberry tarts and Cherry pies; the one just over, the other looming large before. Cherry pie! How can a schoolboy reflect on such dainties, and then be expected to recur with satisfaction to his mean dish of Rhubarb? No: the time to pasture on Rhubarb is from Christmas to green Gooseberry time, and then only occasionally afterwards by way of a change, or in the shape of jam when other fruit is scarce in autumn.

I read with interest the discussion about forcing Rhubarb in the Journal a few weeks since. I must say I think the simplest and most economical way is to take it up, and either plant it in boxes to be placed in a warm dark corner, or out in a bed over heating materials. The way we manage is this: In the shed which covers the fireplace of the forcing house we have a bed of earth about 6 feet long, 3 wide, and 2 deep; this, having a fire constantly burning under it during the winter, keeps quite warm. In this bed the roots are planted out about every three weeks as we want them, and thus a constant supply is kept up. But small roots or pieces will not do; you must have great strong stools weighing about a stone, and put them in just as they are without dividing. Three or four such roots at a time will be enough for a small family, for it is wonderful what a quantity they will produce, and good too. I should by no means call it seconds, but you must not water too freely, or the flavour will not be so good.

After the crop is pulled take up the stools, divide and plant out. We keep up a succession in this way until the outdoor crops are ready. These are grown under pots simply without any covering of fermenting dung. It may be fancy, but I always think that Rhubarb is never so sweet when it has been grown covered down with manure. Somehow or other the flavour of the stables seems to creep in, and when this is the case it is spoiled. I fancy, too, the sun heat on the pots, which in bright weather become very warm, improves the quality. As to pots versus wooden boxes, give me pots. They can be kept cleaner, for there are no crevices; they want no painting, do not crack with the sun or rot at the bottom with the wet; and as to lasting, well, if you do not break them (and why should you?) they will last as long as you do.

"Rhubarb jam is very nice," one of my youngsters remarks, and so it is. You may make it all sorts of colours and all sorts of flavours according to how it has been grown; and if you like to add a few stalks to your Strawberry jam in July you will find it an improvement. You will not taste the Rhubarb, but it will take away the mawkiness which Strawberry jam has as a rule, and impart a slight acidity, besides improving the consistency of the preserve. I know nothing of Rhubarb wine, but have heard that it is good also.—R. W. Beachey.

THE DOUBLE YELLOW WALLFLOWER.

This is a sweet and bright plant for conservatory decoration during the early spring months. There is no better time than the present to propagate plants for next year's blooming. Commonly slips are put in under handlights in June or July, but that is too late to produce stout plants the same season. Neither are old plants suitable for growing in pots, as, besides being leggy and straggling in habit, the spikes and flowers are smaller than those produced by young plants. I have found the following plan the best in preparing plants for forcing. It is as simple as it is effective. Take off the tops of the young shoots and strike in heat after the manner of Verbenas. When struck pinch-out the tops and place the cutting pots in a cold frame. Here let the plants break into fresh growth, and then plant them out in a very exposed place. They do not require rich soil, but they must be planted very thinly. They may have one more stopping after being planted out. By the autumn they will be fine bushy plants for potting, the foliage curling over the pots, and the spikes they throw-up will be stout and bold. In a very light house and gentle forcing they give a fine effect in March and April. For out-door flowering this and other double varieties can be raised in the same way, and the plants are much finer than those raised by slips in the middle of summer.—W. J.

THE FLOWER GARDEN.—No. 2.

The one great fault of beginners in the arrangement of flowers is that of aiming too high in the first instance, instead of feeling the way with one or two simple matters—making a study of every combination, and then gradually extending our measures with the confidence and security of success which experience alone can impart. We too often launch out boldly, spreading the brightest colours with a lavish hand, and with very little regard to harmony of colour or congruity of position. The beds look bright and gay, and we regard them with a certain amount of complacency mingled, it must be owned, with doubts as to what those who are competent to criticise will think of our work. The feeling is natural, because it arises from a conviction of ignorance of all fundamental rules of taste; or it may be caused by the fact of our having copied some design which looked well enough in a large public garden but is totally unsuited for our small one.

While strongly advocating the importance of a knowledge of the laws of colour I would not advise a slavish following of set rules, or attempt to frame arbitrary laws for anyone; for it must never be forgotten that tastes differ, and that colour combinations of a quiet refined tone are not the most attractive in the eyes of everyone. One sees gardens that are perfectly dazzling in their brilliancy, and with which the owners are evidently quite satisfied. Well, if they are content why should we seek to mar their enjoyment of what they consider to be beauty? Certainly we will avoid doing so, but at the same time we must not pander to a depraved taste, which a fondness for glare and glitter really is.

There is a very close analogy in harmony of colour and of music. We take a certain colour and place it with others which we know will impart and receive much additional beauty from such a combination. The musical professor in associating notes of different tone produces harmony to song. The greater the master the more varied and delightful is the music. Those who are proficient in music can read a simple tune at sight, but it requires high culture, refined taste, and a natural aptitude to take in the full significance of the great works of Handel, Mendelssohn, or Rossini. Just so is it in colour. A few simple combinations are seen, copied, and become popular; but the more difficult designs find few copyists because they are seen to be intricate and therefore difficult, and few attempts are made to study and master their details. The exquisite delicacy and loveliness of the various tints when thus interwoven remain invisible to casual observers, and herein, I think, is found one reason for occasional sweeping condemnations of our bedding system.

Turning to the practical part of the subject, I will take for my first example a flower border of an ordinary type and see what can be done with it. Perhaps the most common form is that of a parallelogram placed immediately in front of a belt of shrubs with a sweep of lawn in front of it, and no better position could be required for the display of an attractive floral picture. If the roots of the shrubs must be prevented penetrating the flower border, this is easily done by making a deep open trench between the border and the shrubs, so that the roots cannot cross over.

An easy method of arrangement is that of straight lines or ribbons, and hence the familiar term of "ribbon borders." The plan is so simple that it admits of an almost endless combination of colour. The lines, however, should not be taken straight through and each finish at the end abruptly, but each row should curve backwards, giving a rounded finish to the ends of the border. By this simple and easily understood arrangement the effect will be much more smooth and pleasing than if such row of plants is carried straight through, as is too often the case in planting a border. In the examples of planting the lowest numerals represent the lowest-growing plants, commencing, of course, at the front of each border

and increasing in height towards the back, finishing with the highest as the back row.

A.

6, Rich Yellow — Golden Superb Nosegay Geranium. Flowers kept picked off.
5, Deep Crimson—Coleus Verschaffeltii.
4, Grey—Leucophyton Brownii.
3, Blue—Lobelia Blue Beauty.
2, Carmine—Alternanthera amœna.
1, Pale Yellow—Mesembryanthemum cordifolium variegatum.

B.

6, Purplish Red—Canna rubra superbissima.
5, Pale Yellow—Lady Plymouth Geranium.
4, Dark Blue—Viola Perfection.
3, Crimson—Coleus Verschaffeltii.
2, Lilac—Lobelia Omen.
1, Grey—Santolina incana.

C.

6, Purplish Crimson—Ricinus purpureus major.
5, Grey — Leucophyton Brownii. Not pinched, but left to grow tall.
4, Pale Yellow and Green—Polemonium cœruleum variegatum.
3, Blue—Lobelia Lustrous.
2, Bright Crimson—Coleus Verschaffeltii splendens.
1, Yellow, Pink, and Green—Golden Tricolor Geranium Peter Grieve. Flowers kept picked off.

D.

6, Deep Rich Scarlet—Lobelia Queen Victoria.
5, Pale Yellow—Polemonium cœruleum variegatum.
4, Blue—Lobelia speciosa.
3, Yellow—Golden Feather Pyrethrum.
2, Blue—Lobelia speciosa.
1, Grey—Cerastium tomentosum.

E.

6, Various—Mixed Gladioli.
5, Pale Yellow—Vinca major elegantissima.
4, Blue—Viola Perfection.
3, Green—Tagetes signata pumila. Flowers kept picked off.
2, White—Euonymus radicans variegatus.
1, Green and Black — Sempervivum californicum.

In the three examples A, B, C, it will be seen that with the exception of the Lobelia and Viola the plants are all of kinds that are valued solely for their foliage and not for their flowers, so that there could be no doubt about their continuing in full beauty throughout the season. The Viola and Lobelia are both safe plants, but the introduction of other plants into the design for the effect of their bloasom requires caution, for the evident reason that the failure of a single line would spoil the appearance of the whole. D and E comprise two useful arrangements for amateurs, the Lobelia, Golden Pyrethrum, and Tagetes being easily raised from seed ; the scarlet Lobelia and Polemoninm wintered in a cold frame or pit; the Gladioli stored during winter in a drawer or upon shelves and planted in April; and the Sempervivum, Euonymus, and Vinca being perfectly hardy.—Edward Luckhurst.

THE PINE-APPLE NURSERY.

It is a well-known axiom that we cannot put an old head on young shoulders, but it is within the bounds of possibility that a youug head may be put on old shoulders, as is exemplified in this establishment. It is old in years, yet young in vigour; and if a tone of matured age pervades it, not less certainly does it partake of the buoyancy of youth where enterprise and life are its prominent characteristics. In a word, in the brisk competitive race of the times this nursery is not likely to lag behind in its aims to hold a place abreast of its contemporaries. This is no ordinary position to attain, and it can only be accomplished by a combination of practical skill in home management and the business activity which is essential to make its resources familiar to the outside world. On these principles are founded the success of the most successful examples of the day, and on these lines are based the governing medium by which this nursery sustains its claims to a foremost place in commercial horticulture.

Being situated in a pleasant part of the metropolis, and not devoid of outside attractions, it is not to be wondered at that a considerable sprinkling of rank and fashion daily make a rendezvous of its spacious conservatory, which at all times is worthy of a visit, and especially now it is at or near its zenith of beauty. This structure is exceedingly gay, so gay indeed that one can with difficulty take hold of a given point to commence a description. Therefore, no detailed notice is attempted, but we, in a general way, class it as it is—a grand mass of colour and foliage, blended in a way to command attention, yet almost to defy analysis. The colour, however, is mainly imparted by Azaleas, of which a central plant of A. Leeana is conspicuous, surrounded with a margin of Triteleia uniflora and Lycopods. This is the original plant of this old and good Azalea, which is white with occasional pink flakes, the flowers of good form, and free. As a fine contrast is the darkest and best of the purple Azaleas, Cedo Nulli. A light variety, effective by its bold flowers, is A. Nonpariel, and one of the best of the darks is A. Superba. This is a rich orange scarlet, as free and with flowers as good in form as are those of A. Roi Leopold. The following varieties were also effective:—A. grandis, fine; Grosefürstin Helene, Eugène Mazel, and President. Several Ghent or Chinese Azaleas added their soft yet distinct colours; a plant of the typical variety, A. sinensis, being exceedingly well bloomed.

At the entrance is an excellent specimen of Erica (aristata) Victoria, and a match plant of Aphelexis, both well covered with flowers. Several plants of Amaryllis are interspersed, the best being A. Harrisonii, a pure white ground with maroon stripes ; A. aulica splendens, fiery scarlet ; and the showy A. vittata rubra. Early Pelargoniums, Digby Grande and Monte Christo, proved their usefulness for conservatory decoration in April. The rest of the flowering plants comprise Hydrangeas and Cytisus, with marginal plants of Stocks, Mignonette, Isolepis, and Lycopodiums, to add sweetness and quietness to the brightness of the collection.

The foliage plants consist of Yuccas quadricolor and oleifolia, Cordylines, Palms, and Ferns, not overlooking sundry plants of the Variegated Maple, Acer negundo variegata. These plants are in various sizes, and are admirable for lighting up dark corners and in showing to advantage in grouping in contiguity to masses of dark foliage. For this purpose this common and easily-grown light-foliaged plant is strikingly effective, and should be generally used for decorative purposes during the spring months. On the north side of the edifice a cool and agreeable change is afforded by the rockery where Ferns and Ivy luxuriate in a semi-natural state ; the Dicksonias especially growing with exceptional vigour.

The remainder of the glass structures, which are numerous, are filled with a general collection of plants, mostly of a handy portable size, and in excellent order. Not many large specimens are to be seen, yet we noticed good Alocacias, an excellent form of Anthurium Scherzerianum large in size and rich in colour, Musa ensete, Curculigo recurvata, a nice stock of the useful Palms Plectocoma Andersonii and Cocus Weddelliana, good Gleichenias, &c. It is not, however, for a few large specimens, but for immense stocks of medium-sized and small plants that the nursery is noticeable. Dracænas, Eucharis, Gardenias, Heaths, Pelargoniums, &c., are provided in thousands to meet the running demand on decorative plants of this nature.

Altogether the nursery is worthy a visit alike to the pleasure-seeker looking for a fine floral display, and to the gardener who is as much interested to see work in progress as when perfected and completed. Mr. Beater's supervision cannot fail to be appreciated alike by the Company and the public.

LITHOSPERMUM PROSTRATUM.

As spring-flowering border plants are now being sought after, this beautiful hardy evergreen trailer is recommended as worthy of culture. Although the habit of the plant is procumbent, it is still compact, and a good plant a foot high and through when clothed with its deep blue flowers is exceedingly attractive. It will grow in ordinary garden soil, but has a preference for an admixture of peat. It is a native of France, but is quite hardy. The colour of the flowers is very rich, and show to advantage in the bright green setting of the foliage. As a pot plant it is very attractive at this season of the year; indeed in the collections of hardy plants staged at South Kensington last week, no plant was more distinct and effective than this lowly yet lively Lithospermum. It is increased by cuttings; young shoots put in at the present time in gentle heat will strike readily, and will make nice plants by the end of the season. It may also be raised by seed. It is useful for the rockery, for associating with Iberis and other low-growing spring-flowering plants, and as a pot plant in the front row of the greenhouse or conservatory. It is not a gaudy, but is an interesting little plant, possessing inherent beauty, and has claims to extended cultivation.—W.

Fruit Prospects in Lincolnshire.—A nice change in the weather has set in; but bright sunny days are followed by frosty nights. On the 14th ult. the thermometer stood at 20° at 6 A.M., and before 12 o'clock the mercury had risen to 60° —a rise of 40° in less than six hours. Fruit trees are densely clothed with blossom. Pears and Plums are well open; so far

they are not injured, and there is every prospect of an abundant crop of fruit.—G. R. Allis.

PEACH FORCING.—No. 3.

Planting.—It has already been stated that the trees for house planting ought to be of fruiting size, and planted in their stations as early in autumn as the state of the growth permits, which is when the leaves begin to fall. If a few leaves remain at planting there is no harm, if the wood be ripe and the buds prominent. As the trees, however, will not be available for early forcing the first season there is no need to be in a hurry in planting, the leaves may be all fallen, though when moved with a few leaves there is a prospect of adventitious roots being formed by the descending current of sap, which gives an advantage to such trees over those moved in a decidedly dormant state. In planting, allowance must be made for the lowering of the soil, which will settle to a greater or lesser extent according to the lightness or firmness of its nature; even if the border be made as hard as possible it will sink, and this I have known to vary from 6 to 9 inches. In any case the trees should be planted high—at least 6 inches above the present level, the setting-on of the roots being that height above the level of the border, which will be equal to planting the trees on a slight mound; and this ought to be continued some distance outwards from the stem, so that the mound will scarcely be apparent. This may seem a small matter, and yet it is one which unattended to renders surface-dressings impracticable, as these only sink the stems lower in the soil when the trees are planted with the setting-on of the roots level with the border; and yet surface-dressings are very important, and equally so is the keeping of the stem of the trees from being buried deeper than they were at planting. The burying of the stem is preventive of successful culture and healthy trees, as a multitude of suckers are sent up from the roots, and the growths of trees become weak and die back. Avoid deep planting and low planting, and spread out the roots near the surface, and make the soil firm about them. It is useless to rectify any evils of planting in after years. Forced Peaches do not lift as readily as outdoor trees, and require no check after they are once forced, but rather need encouragement by judiciously applied artificial stimulants and support.

In planting, the space to be allotted to each tree will necessarily have to be considered. It is remarkable what a large space a Peach tree will cover, but then some time must elapse before it does so. I am not an advocate of monster trees, though where they exist by all means retain them, but do not plant with a view to them, unless prepared to have lost space for a number of years. Moderate-sized trees are in every way as good as large ones, and there is an advantage in the allotted space being covered in a shorter time. The width of the trellis will have much to do with the distance of the trees; 15 feet apart is ample for a trellis 12 feet in width, 18 feet for a 10-feet trellis, and 3 feet increased distance for every 18 inches decrease in width of trellis. Those are the distances I consider most desirable, but as the trees have in their horizontal parts—the lower parts of the trellis—a tendency to grow less and weakly, I do not advise increasing the distance, as that would be to extend the horizontal surface, but on the other hand I would lessen it if any departure were made from the distance named.

After planting, the trees should be thoroughly watered, and during the period of rest the border should be kept in a moist condition. It is a mistake to think trees in a dormant state require a "dry as dust" state of the soil; nothing of the kind have they in nature, and in practice it is undesirable, as it often causes the buds to be cast when they are expected to expand into flower. Not that the soil requires to be saturated to soddenness, but to be kept in a moist state, and this will be the case if the lights are removed when the trees are at rest, or the borders partly within and partly outside. If entirely within they should be occasionally examined, and watered.

Preparing for Forcing.—When the leaves have all fallen the trees should be loosened from the trellis, the woodwork be thoroughly cleansed with soap and water, and the glass with water only. If the house requires painting it ought to be done as well, or any required repairs, the structure being thoroughly scrutinised and be put into good order. The trees will next require to be pruned, and this done they should have every part dressed with tobacco juice, adding to every gallon 1 lb. of soft soap. This will destroy the red spider and the brown or Peach aphis, which is troublesome upon the wood of Peach trees in a dormant state and in the early stages of growth. The brown scale is not an unfrequent infestor of Peach trees under glass. It may be destroyed by adding to the above admixture of soft soap and tobacco juice two wineglassfuls of spirits of turpentine. In either case the composition is best applied at a temperature of between 90° and 120°, and to be effectual it requires to be thoroughly applied, not putting it on the face of the branches and shoots only, but on the back as well as the front, every part being thoroughly wetted, angles as well as smooth parts, but at the same time being careful not to dislocate or injure the buds by too heavy brushing, and especially in a downward direction. A stiff brush is not suitable, but what would be considered a good tool by a painter answers perfectly.

Tying of the trees will need to be done neatly, and loosely rather than tight, and the matting twisted once round the wire, which will not allow of the shoot being displaced, and at the same time will keep the wood from coming in contact with the wire. The border if it have a hard caked surface should be loosened very lightly with a fork, not disturbing any roots. See that the soil is closed to the walls, the front wall being arched make the soil close up to their crown, and have all fine on the surface. Top-dress with 2 inches thickness of equal parts turfy loam and short manure, completing, if the lights are not to be removed, with a thorough watering to the inside border, which will be sufficient to keep the trees in a moist state at the roots until forcing is commenced; if the lights are removed the watering will be unnecessary, and yet any parts not likely to be reached by rains should be thoroughly watered.—G. Abbey.

PRIMULA ACAULIS AND ITS VARIETIES.

Why people do not take the trouble (for it consists in nothing else) of obtaining the beautiful varieties of this plant I cannot understand. Surely Primula japonica and P. cortusoides amœna, to say nothing of P. denticulata, P. verticillata, &c., undeservedly in comparison have so much more care bestowed on them, in consequence, I presume, of their greater scarceness and novelty, and also, perhaps, because of the labyrinth of rubbish in which the beautiful kinds of Primula acaulis are unfortunately involved, due to the extravagant amount of tints to which the flower is subject by seed. All blossoms with washy and indistinct colours should be at once discarded, and those with decided, and more especially clear and bright shades, should separately be selected, and having been propagated in sufficient quantity for massing they would display their beauty to advantage, varying in shades of crimson, yellow, purple and white. Thus, what a choice the single and exquisite double-flowering Primula acaulis offers us. The latter more intrinsically beautiful, but wanting, for the most part, greater nicety of treatment, whilst the former positively require little or no attention, and yield a greater diversity of hue, affording also a wider interest by increasing themselves from seed, and thus more perfect varieties still may be rightly expected.

A bed of nearly three hundred plants of Primula acaulis purpurea in my garden has been a mass of colour since the end of February. What an effect could be produced by other beds massed in the same way with other distinct shades.

The common yellow Primrose varying in its wild state but little in colour, may often be found differing in form, some having more, some less, lobes to the corolla, the edge of which may be either notched or smooth, occasionally forming an almost unbroken circle, which strain is much to be desired. In this case the lobes partly overlap each other, giving apparently more substance to the flower.

As a pot plant for the greenhouse (for which purpose I think it is as well taken from the open border when required with a tolerable amount of earth clinging to its roots), it blooms without artificial heat some weeks earlier than when unprotected. I think nothing can be more attractive. Whilst out of doors, whether under the shade of trees or in the open ground, it literally hides its foliage with blossoms, forming as it were a cushion of nearly every shade of colour.

Primula elatior is so nearly allied to Primula acaulis that I have known their seedlings sometimes partake of both forms. The Oxlip in its natural state I can vouch for as growing in many a Suffolk wood, and produces somewhat the effect of a cluster of Primroses issuing from a Cowslip stalk.

The Polyanthus, more especially valued for its beautiful lacings and minute pencillings, will always claim its special

admirers. It has to my knowledge but few of its class with decided and attractive colours as yet. I contend, in conclusion, it is the harbouring of inferior varieties, mostly nondescript in colour, which tends to create a heterogeneous strain, thus degenerating instead of improving this beautiful class of flowers, and rendering it a plant of second-rate favour.—Henry W. Cooper, *Surrey*.

CHILIAN BEET FOR WINTER DECORATION.

A bad strain of this decorative plant is one of the most rubbishy impediments that a garden can be troubled with. The worst of it is, its badness is not proved until the plants have attained a good size, and the blanks left by pulling them up are not easy to fill up satisfactorily. But a good strain is decidedly ornamental, its massive foliage, high colour, and bold growth adding an agreeable diversity to the general effect. Unfortunately, however, in good strains are bad plants, and, if planted in a row, to take these away leaves ugly gaps, and to allow them to remain is to cultivate unsightly mongrels. It is quite likely that this inconstancy may drive this Beet out of our gardens, and its use be lost for that purpose for which it is really useful. My practice in growing has never been to rely on it as a summer garden plant, but it has served me well as a winter and spring ornament both in conservatory and hall.

For this purpose I grow a batch in any convenient part of the kitchen garden, and keep weeding out the worst as they show their character, and in the end have generally a dozen or two left of really brilliant colours. These are potted up in the autumn and kept in pits from frost, and introduced as required for associating with flowering plants both under glass and for grouping in corridors and on staircases. Thus used on special occasions they have saved the life of many a Dracæna, and have created an effect, by gaslight especially, that few, if any, tropical plants could equal.

For mixing with plants of Centaurea, a few Chrysanthemums, or Primulas, high-coloured plants of this Beet are really useful in the depth of winter where more tender plants could not be placed without great anxiety. I can recommend it for that purpose, because I have proved its worth, and have witnessed how satisfactory it has been to those for whose gratification the groups of plants have been arranged. More than once it has been a sad puzzle as to what the brilliant-coloured plants could be which looked so tender yet were so hardy as to be placed in all sorts of draughty positions without care or compunction.

To those who are called upon to furnish ornamental groupings in winter, and whose resources are greater for killing tender plants than for raising them, I advise a trial of selected plants of Chilian Beet. Sow the seed in the open garden about the first week in May, and transplant in any convenient place in which to prove and select the best. Pot up in October, and when established give them a little liquid manure to enhance the colour of the foliage. The plants are never more effective than when bolting for bloom in the spring, when the best can be replanted in the garden to ripen their seed.—Anglo-Saxon.

OUR BORDER FLOWERS—THE COLUMBINE.

Perhaps there is no race of plants that affords us more diversity of colour in their flowers than the Columbine. With the exception of a pure scarlet I think they give us all the intermediate shades to be found in flowers. I have seen them in some woodland scenery growing on a gravelly hill in partial shade among the grass and decomposing leaves in their thousands. In such places they are seen to perfection in single, double, and semi-double varieties. They are a race that are easy to manage, for under the above circumstances all they require is just simply to be left alone; they reproduce themselves rapidly from seed when once established. They will grow almost anywhere provided they have light and air. These plants are among the very best for cut flowers, where such are in demand, as affording a continuous supply for a great length of time. There is a variegated form of the Aquilegia vulgaris, and when well established it is a very striking plant as a border flower.

When we turn our attention to the imported varieties we find some of Nature's choicest gems. To have them in perfection they should be grown in beds or groups, selected according to their habits and contrast of colour, yet as single plants in the border few flowers can surpass them. They delight in a moist but not wet soil—that sometimes proves fatal to their well-doing. Sandy fibrous loam and decayed vegetable matter, with a sprinkling of coarse grit well incorporated into the border, form a suitable soil; this should be broken up to the depth of 2 feet, to afford the roots room to develope themselves. The taller kinds should be staked as they advance in growth, to prevent the wind from breaking them. Some of the choicer kinds are well adapted for exhibition purposes. Some of the dwarfer species are splendid plants for the rockery. To keep them true to name they are increased by division when the bloom is past. New varieties are obtained from seed.

Aquilegia arctica is a very fine variety, with blue and white flowers. A. siberica is of compact habit, its large blue and white flowers have a fine effect; it ought to be more extensively grown than it is. A. chrysantha is a novelty of no mean order, its beautiful yellow flowers and graceful habit entitles it to a place in every garden. A. glandulosa is one of the best, it makes a grand display as a border flower. A. alpina is a very choice kind for the rockery or border; it requires shade and moisture. A. olympica is one of the largest-flowering varieties we have, and is well adapted for rockery or border. A. cærulea is a charming variety of dwarf habit; no collection should be without it. A. Skinneri is a dwarf and early-flowering beautiful variety; it is able to hold its own against all comers, and ought to have a place in every collection. Its orange and scarlet-coloured flowers render it a very conspicuous object whenever it is met with in good condition. A. canadensis is very seldom met with; it is said to have been introduced more than two hundred years ago. It is one of the tallest of the race. All the varieties are effective and of easy culture. Their cultivation is strongly recommended.—Veritas.

RECUPERATIVE POWER IN PLANTS.

Thinking the following may be of general interest, I send it, hoping that it may elicit some discussion.

In my garden I have a row of about fifty young Currant bushes, principally Red and White, with here and there a Black. At the beginning of February the sparrows and other birds made a vigorous onslaught on the buds of these said bushes, completely pecking them out, and leaving the branches as smooth and free from buds as if the rods had been individually drawn through the fingers and the buds rubbed off. The Black Currants alone escaped this infliction, probably in consequence of their strong aroma being distasteful to our "feathered friends."

Having noticed the completeness with which the birds had stripped off every bud from the bushes, I was fearful lest the plants themselves should die, or at least suffer very much, and consequently watched with some anxiety to see the turn which things would take. Judge my surprise when, about three weeks after this Promethean infliction, I found that the bushes were again putting forth buds, some in the exact locality of the wound, and others at different portions of the stems.

Now, not only are the bushes clothed with opening leaf buds, but the show of flower buds is also very large, and seems to promise (weather permitting) an abundant crop of fruit.—Selimo Bottone.—(*English Mechanic.*)

[We are enabled to give confirmatory evidence of the vitality of Gooseberry and Currant bushes under the same circumstances. We have, in the case of vigorous trees, observed that where the birds had taken the primary buds a pair of latent or adventitious buds pushed from the base of each. These have produced fruit, but smaller—as the growth was more weakly—than that from the principal buds. We have also frequently noticed that where birds had picked off the tops of Peas when just bursting the ground, that each Pea had sprung two dormant buds from the base of the original growth, which have made weakly haulm and even produced flowers. This is only the case with large Peas sown somewhat late in the season, and when the ground is warm; Peas from small seed from which the tops have been picked early invariably decay. Kidney Beans which have been cut by frost will, if the frozen part is cut over immediately and the downward decay of the stem arrested, push fresh eyes and grow, providing the soil is not too cold and wet; fair crops have been had from Beans so cut down. —Eds.]

NOTES AND GLEANINGS.

At the Fungus Show held in Aberdeen last September, a committee was appointed to organise a Scottish Cryptogamic Botanical Society, and on the 16th inst. a meeting, attended by botanists from various parts of Scotland, was held

at Perth to found the Society. It is purposed to have a show of Fungi, Mosses, Ferns, and other cryptogamic plants every year in various districts of Scotland in rotation. The following office-bearers were elected:—President, Sir T. Moncrieffe, of Moncreiffe, Bart.; Vice-president, Professor Dickie, Aberdeen; Secretary, Dr. Buchan White, F.L.S., Perth; and Treasurer, Rev. J. Stevenson, Glamis.—(*English Mechanic.*)

—— There is an increasing demand for land in Ceylon for the purpose of growing Tea, Cinnamon, Cinchona, Vanilla, and other useful plants for economical purposes, as well as for the spread of the Coffee plantations. A disease in the Coffee plant has lately been discovered which threatens scarcity of this product unless speedily checked. It is called "leaf disease," and, as its name implies, is principally apparent in the dearth of foliage, though the produce of the berries is also considerably reduced. It is believed by competent authorities to be mainly caused by exhaustion, and is in this respect similar to the disease among the Lemon groves of Europe, to which we alluded a week or two ago. The Government of Ceylon have taken up the subject with a view to its thorough investigation.—(*Nature.*)

—— The Acclimatisation Gardens in the Bois de Boulogne, Paris, have received a rare collection of Artificially Coloured Plants from China. The plants are exhibited in the great glass house of the gardens, and excite universal admiration. Among the collection is a dwarf tree of half a metre in height, the trunk of which is as thick as a finger, and the root of which hardly fills the hollow of a man's hand; the specimen is about one hundred years old, and is a species of Oak. This, however, is not a natural phenomenon, but the result of Chinese horticulture, which finds its highest problem in the reduction of the natural size of plants.—(*Nature.*)

—— The "Sanitary Review," a new monthly penny periodical, states that the proposal to form a Public Garden within the district of St. George's in the East has been favourably received by the vestry. A memorial signed by 650 inhabitants, including many of the most influential ratepayers, was presented in favour of forming a public garden at the east end of the parish churchyard, and making a thoroughfare through the churchyard from St. George Street to Cable Street.

NOTES FROM MY GARDEN IN 1874.

ROSES.

So much has been said on the subject of the queen of flowers in the Journal, and so well said, that I fear any little contribution that I may make to it on the subject of Roses in my own garden will not be of much avail. Still, the same principle that has led me to believe that notices from my small plot might be of service to others leads me to add a few remarks to those which I have already made on other subjects.

I have frequently stated that mine is not a good Rose soil; and although it will grow most plants well, those which require, as the Rose does, a tenacious loam, fare but indifferently. In dry seasons this is more especially the case, and what I have suffered from orange fungus I have already detailed to the sympathising Rose lovers of our Journal. Last year happily I did not suffer to the same extent, whether owing to the season or to the fact of having introduced some loam (of rather too sandy a nature, I fear) into the garden, I cannot say; but certain it is my trees did not present the same deplorable appearance they have done for the last two years, while during the winter I have had but very few losses. Some alterations I made will, I hope, add to my enjoyment of the queen of flowers. This year I have made my little rosarium larger, and have planted on my wall, to occupy the spaces until the fruit trees fall in, some of the newer Teas on Mr. Prince's seedling Briar stock.

The two plants about which I am proudest are those of Cloth of Gold and Rêve d'Or, which are now fast covering my house. Of the former I had some truly grand blooms and clusters of blooms, and if it goes on at the same rate for a couple of years longer I shall no longer cast envious eyes at my neighbour Miss Whittles' truly grand tree. As to Rêve d'Or, I do not know where it will stop: it has forced its way right through the open woodwork of the gable, and is creeping round to cover the north side of the house as well. It was this last season clothed with bloom from the base up to the uttermost branches, and I may say that a plant budded from it on to a standard Briar was filled with bloom; so that I cannot understand that anyone has found it to be a shy bloomer. With me it is the most floriferous Rose I have. The plant alluded to above I gave to a friend to cover his vicarage, which I hope it will do; and I know of nothing better for the purpose, for it is nearly if not quite evergreen. A plant which I supposed to be Climbing Devoniensis planted by my yard door has turned out to be Maréchal Niel; and although I do not like the Rose for outdoor decoration, as it hangs its head and displays the decaying outer petals, yet I have been obliged to give it space, and have fixed on the top of the wall a wire netting 4 feet high for it to run along. A Solfaterre on the front of my house has also made rapid growth, so that I shall soon have, I hope, enough of yellow Roses.

There was a time in my select days as a Rose-grower when novelties had their wondrous charm for me. No French dame sallying out to see the "loves" of new bonnets at Longchamps was more eager than I to find out the new Roses that under the description of *magnifique*, *superbe*, *très grand effet*, dazzled one's eyes as each new catalogue appeared. But, alas! experience has cooled one's ardour, and I can look down the longest list of novelties with a sort of icy coldness that contrasts very forcibly with the feverishness of former days; and I am contented to wait until I see their merits or demerits decided elsewhere. And how very few Roses of real merit the past year or two have given to us! I had a small plant of Capitaine Christy; and not only from what I saw then, but from plants I saw at Mr. George Paul's, and from a fine box of blooms exhibited by him at South Kensington, I am inclined to think very favourably of it, my only question being whether it will sufficiently stand weather. Of the other new Roses of last season I had none.

As to sorts I may endorse what my friend Mr. Peach has said, after the careful and elaborate Rose election carried out by Mr. Hinton, for which all lovers of the flower owe him many thanks. It is preposterous to be asking for or giving lists, unless it may be that some peculiarity of soil or situation demands some special kinds. There are some which have a hardier constitution than others, and hence a novice might in a trying locality require some guidance, otherwise for some time to come those lists ought to answer all purposes. I have again added to my stock some on the seedling Briar. But, after all, why should I talk of my stock? I have not more than some six hundred Roses altogether, and these are put into a much smaller space than a true Rose-grower would desire to have them, and I can well imagine the smile of pity which flits across the face of some of my Rose friends as they think of my little lot compared with their magnificent stud. Well, be it so; on the other hand there are many who would like to grow six hundred, and therefore I may well be satisfied. I am not an exhibitor of them, or I should require a vastly larger number. They are now sending forth their dark healthy-looking shoots, and I hope to have much enjoyment of them during the coming season.—D., *Deal.*

STOCKS AND ASTERS.

The season is fast approaching when the seed of these delightful annuals ought to be sown. They are familiar to most people, and, in my opinion, no garden of any pretensions ought to be without them. Stocks and Asters may be called everybody's flowers. They possess so many good qualities. Their sweetness, their various colours, and their adaptability for cut flowers place them high in the ranks of annuals. My object is to simplify their cultivation, as I believe many people are labouring under the impression that unless they possess a hotbed and a frame that it is next to useless to attempt to grow them. In nine cases out of ten they are so produced, and the plants are already in a forward state. I have myself adopted the same mode of raising them, simply because it has been a custom. Those who want early blooms must, of course, sow accordingly; in this case I shall call them summer flowers, but I am of opinion that they are more autumnal than summer flowers. I will here detail my own practice for the last two or three years, which has reduced the labour of raising Stock and Aster seeds to a minimum.

They are grown in the kitchen garden on the side borders of a central walk between 70 and 80 yards long. On these borders are planted standard Roses about 2 feet from the Box edgings. A good dressing of well-rotted manure is every year given, and what is good for the Rose is equally good for the annuals. The borders are nicely levelled with a rake, then a drill is drawn 2 feet from the Box edging, and about 2 inches deep in a line with the Roses; this drill is for Asters. I then

mark out another drill a foot from the first; this is for Stocks. It is important to have the colours varied as much as possible for the sake of contrast. In sowing I proceed as though I were sowing Onion seed, and at the end of each kind I place a label; this keeps each colour separate, and is also convenient to make any notes when they are in bloom. I make it a point to cover the seeds lightly with sifted ashes from a burnt rubbish-heap. It is best sprinkled on by the hand from a flower pot or saucer. Perhaps some may think this is a very rough way, and would prefer to have the borders nicely levelled and raked, but I think I shall be able to show that these drills or trenches are of great importance. Little details are often the secret to success, and these trenches are a provision for watering; if this is not required by the watering pots the drills will better retain Nature's watering. Seed beds are often raised in the centre, and are smoothly levelled; but mark the results of this plan after a smart shower of rain, followed by a parching sun and drying winds. The result is a hard-baked surface, particularly so if the soil is of a strong binding nature. If the weather should continue dry, waterings will be required, but it will be found that through this dry and hard surface the water will not readily penetrate, but will be found to run off, and to make it enter under such circumstances the Dutch hoe or fork tines must be used; but suppose the seeds are germinating they are apt to be rooted-up by the operation. Now, if I had a circular bed to sow I would begin at the centre and make circular drills at a certain distance apart.

The seeds should be thinly sown, I say thinly because Stocks and Aster seeds are too costly to be lavishly sown; indeed, sowing too thickly is often attended with bad results; it is a waste of seed, and the plants are drawn-up thin and weakly. In such cases they ought to be thinned early. Many half-hardy annuals might be raised by placing good-sized inverted flower pots on borders, and sow under them, and after germination gradually inure the plants to the light and sun, but cover at nights if there is frost. The covering will have its advantage by keeping at bay slugs and other enemies until the plants gain sufficient strength to do without any protection. Stocks and Asters, particularly the former, by not sowing too thickly can grow on for some time without injury, indeed until they begin to show their blooms; then is the time to thin—that is, by weeding-out the single flowers.

Snails are particularly fond of Stocks, and the best advice I can give is to catch and kill them. An hour or two after dark they will be found emerging from their abodes to make their night attack, then with a lantern and a flower pot make the sortie on their lines. The first week in May is soon enough to sow the seed. In referring to my diary of last year they were sown on the 16th of May, but that was too late, and it was delayed owing to the dry weather; but by the middle of September they were a grand sight, and at no time of the year are they seen to better advantage, for they last so much longer, and their colours stand much better than in summer. This border is for cut flowers, for we rarely cut any from the flower garden.

Just a word or two about watering. This is a very important question. When watering is necessary let it be done thoroughly. A good watering two or three times a-week is much better than giving dribblets every day. Water should never be allowed to run off in streams. I think that watering is oftener done than is really necessary; for that reason I avoid watering as long as possible, for when once begun it must be continued.

Those who have neither hotbed or frame need not be deterred from sowing half-hardy annuals in May. The plan is commendable for many reasons. First, it lessens labour; second, the plants receive no check after sowing; third, they will bloom better and last longer, as the sun will have less power, and the weather a little cooler. When sown on hotbeds or in seed pans they are, as a rule, sown thickly, become drawn up weakly, and are often, through pressure of other work, left too long in a crowded state. In such cases they are ill adapted to bear the fierce rays of a May or June sun, so that those sown in the borders will often run a close race with those sown earlier. Asters, when sufficiently large to bear handling, may be planted elsewhere. They will stand the operation better than Stocks. As I have remarked, leaving the Stocks thick is simply for the purpose of selecting the double flowers for a permanency. The hotbed plan has its advantages to those who want early Stocks and Asters, and those who wish to prolong the season can do so by sowing as I have stated to give a succession to the end of the season. This border is usually doing good duty when the flower garden is on the wane.—G. R. Allis.

NOTES on VILLA and SUBURBAN GARDENING.

Street Gardens and Spring Flowers.—What I mean by street gardens are those small enclosures generally to be found attached to residences outside of the business portion of a town. These are admirable places for a display of miniature tasteful gardening of a humble kind. True, there are many examples one can easily observe as we travel on where the simple yet pretty flowers are cultivated, and where neatness and nice arrangement is prevalent; but by far the greater portion of these enclosures are not managed as they ought to be and could be, with very little trouble, by using some of the humble flowers of the season. A person passing by one of these little gardens that is cared for and kept in a creditable order will quickly see what a cheerful aspect it gives to the place, to say nothing of the enjoyment that the residents obtain from its appearance and the healthy exercise they derive from attending to the work of it.

It may be that some plants will not flower in some of these places, as their position is occasionally adverse to the well-doing of many plants, principally, perhaps, from the want of sun; but there are plants that will suit any place in any position, and every place does at least offer a little scope for neat arrangement of the soil, such as laying out miniature beds and narrow paths, all of which must be guided by the shape, size, and condition of the enclosure. This once done according to taste, and it is easy to edge the narrow borders with a few plants of Thrift, double red Daisies, or even the common yellow Primrose or a narrow strip of turf, all of which make capital and attractive edgings. Then, if there is room, a plant or two of the Ribes or red Flowering Currant, and two or three standard Roses, and perhaps an evergreen or two, such as Thuja aurea or an Aucuba japonica, both of which suit town gardens and in most cases grow well, and then to clothe the ground around them with a few patches of Musk and Mignonette, which both thrive in either the sun or shade. Common blue and white Violets and Hepaticas, which are excellent spring flowers, and deserve a better patronage among gardeners as well as amateurs, should be freely planted. Other flowers not to be omitted are Forget-me-nots, Pinks, Lily of the Valley, Sweet Williams, Antirrhinums, Polyanthus, Stocks and Wallflowers, as well as Crocuses, Snowdrops, Tulips, common white and other Lilies. Many other plants, of which there is no lack, might be mentioned as easy to grow and inexpensive to purchase.

I have purposely refrained from naming anything difficult to buy or grow, believing that for the purpose I have in view—which is to induce people to give a little time and attention to these enclosures and have the pleasure of doing a bit of garden work of their own—that simple hardy flowers are undoubtedly the best to begin with and the most certain to secure success.

It may be that some would fancy arranging the space as a miniature rock garden in a simple form, the materials for which might be easy to obtain; if so, there are suitable plants for that sort of garden. On spots where the sun cannot shine a garden of this kind would be sure to please. It is very nice to build up a little mound of stones or burnt bricks, clinkers, roots, &c., and to see such charming plants as Arabis albida and Aubrietia purpurea, one a white and the other a blue flower, dangling down and over at places with their multitudes of flowers to grace the spot. The commoner sorts of hedge Ferns planted here and there will enhance the pleasure and beauty of this garden; so would the St. John's Wort. Some of the large and small-leaved Saxifragas are very suitable for covering rocks; most of the Sedums, too, cling very closely to such materials, and clothe the place in winter as well as summer. Places might also be found for Musk, the yellow as well as the green-leaved Vincas, patches of Violets, Lily of the Valley, Solomon's Seal, Forget-me-nots, and many more; and during the summer several flowers of a more tender nature may be placed here and three each of which would add a speck of beauty to the little spot.

To this garden add a window or two decorated with plants, with all things kept in good order, and there would be much to be proud of, and many might have a spice of envy at so nice an arrangement with such common materials.—Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

The weather has permitted us to have all the work well forward, but it still continues cold with frost at night. On Wednesday morning the 21st the wind changed to the west, and the day opened fine, but just as we were rejoicing in the delightful change the weathercock gradually veered round, and before sunset the old biting east wind was blowing. It is well that the sun has an opportunity to shine so that the ground becomes warm in the day, and the radiation from it by night

tempers to some extent the force of the chill blast, and the surface of the ground is so dry that nothing seems to be injured, and what is also much in favour of the growing crops is the fact that we have had no warm weather this season to accelerate growth.

The early Potatoes on warm borders are through the ground, but in order to save them from the effects of frost a little mould has been drawn over the hanlm with a hoe; we ran the hoe between the rows to destroy weeds and aërate the ground. Broad Beans have come through the ground rather strongly. These have also been hoed, and a little mould drawn up to the stems. We generally obtain a good supply of Radishes from under the ground vineries, by sowing between the rows of Carrots and Lettuce; they must be pulled out before they have time to injure the later crops. Any very slight glass protection of this sort is very useful; garden crops that are required early may be forwarded a month or six weeks at but a very trifling expense.

The crops of Onions, Carrots, Parsnips, &c., have come up beautifully and will require thinning out in a week or two, but we would rather have a change of weather before this is done. There is plenty of moisture yet in the ground, and we would rather not have rain until the weather is warmer. The spring-sown Cauliflower plants have been planted out in the open ground, having been previously hardened by exposure to the weather. Drills were drawn 2 feet apart, about 3 inches deep, and the plants carefully planted 2 feet apart in the drills. The ridge on each side effectually protects the plants from cutting winds, and by the time that it is necessary to hoe the ground the stalks will have grown sufficiently to require the ridges to be levelled during the operation of hoeing. Brussels Sprouts were some time ago sown in drills drawn in the same manner. We have found that the plants allowed to remain permanently in these drills do better than those transplanted. We do some both ways, as some seasons, mayhap, the transplanted sprouts would be the best.

We are cutting Asparagus from the open ground from the new sort, Connover's Colossal. We have not been able to distinguish the new sort from the old when a bundle of each were placed together; but if the one is earlier than the other it will be a very material gain. We have sown some Dwarf Kidney Beans in a sheltered position; the Newington Wonder is considered our best early variety, and for the general crop no better variety need be desired than Negro. We made another sowing of Peas, and sowed Spinach between the rows.

FRUIT AND FORCING HOUSES.

Pineries.—The work in this department at present is comparatively easy. In the fruiting houses where fruit in various stages are approaching to ripeness if necessary a high temperature may be kept up, but the precaution we have always advocated should be taken to open the lights at the top of the house early in the morning, admitting air afterwards as it is required, and this must be done cautiously; although Pines do not suffer from injudicious ventilation as do Vines, Cucumbers, and Melons, still the east wind may work mischief if admitted in large volumes. Some growers are recommending shading, but we protest against this until the days become hot. In our modern houses the panes of glass are large and easily acted upon by the sun, so that a slight shade is an advantage from 10 A.M. to 2 P.M. At present any ripening fruit may be protected from the sun by a sheet of paper raised above the fruit; this saves it from injury, and is all the shading required in Pine houses for some time to come.

Plants which are ripening fruit require but little water at the roots, and plants in pots are frequently injured from receiving too much. It is seldom that a plant requires water after the fruit changes to the ripening colour, and we never give manure water after the fruit has swelled to about half its size. Weak manure water applied at alternate waterings may not be injurious up to within, say, six weeks of the fruit ripening, but an overdose causes it to become black at the core. Excellent Pines are produced without manure water, and it is best to err on the safe side. Shut all the houses up early in the afternoon after syringing underneath the plants, damping the paths and walls. Utilise sun heat as much as possible; it is best for the plants and saves fuel.

CUCUMBER AND MELON HOUSES.

Our Cucumbers have not given us much satisfaction this year, notwithstanding more than ordinary care was taken with them. At midwinter they stopped growing without any apparent cause; the old leaves still remained green, but the young growths with leaves up to the size of a penny died. Evidently the roots were in a bad state, and it was a question whether it would be better to pull them out; they were, however, allowed to remain and were carefully tended. In a month young growths were put out and the plants recovered. It was our impression that too much moisture was kept up in the atmosphere, and perhaps too much was applied to the roots. They are now doing well and supplying fine Cucumbers. Some of the old soil has been removed, and fresh compost placed near the roots.

The Melons are now in flower, but before setting any of them a sufficient number of fruitful blossoms must be in flower about the same time. If one or two are set only two days before the others these will run away with the strength of the plant, and the fruit later set will not swell well. Should red spider appear either on Cucumber or Melon plants the only way to check it is to syringe the plants daily with rain water that has stood in the house a few hours.

ORCHARD HOUSE.

The Peach and Nectarine trees have now passed the setting period, and the fruit has set abundantly. Pear and Plum trees are now in blossom, and we are not sure of a good set on them; the rougher the house is that is constructed for them the better. If the glass is put in so that there is a little ventilation at every lap, and if the ventilators cannot be shut close by an inch or so all the better. Our house is far too well constructed for Pears and Plums, there is little or no ventilation except by the ordinary openings. In the rough houses at Sawbridgeworth, and in one we have seen in Mr. John Fraser's nurseries at the Lea Bridge Road, Pears, Plums, and Cherries set without any trouble. A little ventilation ought to be left on at night to cause a circulation. Avoid spilling water in the daytime, and the east wind drawing through the house when the sun shines does good.

Strawberries on the shelves have been thinned out to give those that remain a fair chance. It ought to be noted here that Strawberries will do no good if the plants are crowded.

PLANT STOVE AND ORCHID HOUSES.

Caladiums have been shaken out of the pots and repotted in others; the plants were first started into growth. The compost used is turfy loam, peat, and some rotted manure. The plants are placed quite close to the glass, as nothing looks worse than to see Caladium leaves with long and weak stalks that will not bear the weight of the leaf. When foliage plants are badly grown they are not adapted for any decorative purpose whatever. Other foliage plants require repotting, and it is not well to allow them to become potbound; most of the foliage plants adapted to stove culture require to be grown rapidly and must not be checked. Ferns are the same, the roots are not readily discerned, and a plant may become potbound before it is noticed. They should be repotted as soon as the roots begin to grow amongst the drainage.

All Orchids in baskets or pots which are making fresh roots must now be examined, and chopped sphagnum with some turfy peat be placed round them. Those in small pots may be repotted into larger, taking care to preserve the roots as much as possible, and it is also better to under than over-pot. It must also be noted that all the Phalænopses and most of the Cypripediums require much shade, while Cattleyas and Dendrobiums require only to be protected from bright sunshine.

FLOWER GARDEN.

Mr. Record attends to this department so ably that little is left to be included in the "Doings." Alluding to Pinks he says, Plant them out at once. Of course, if they are not out, the sooner the better; but to do any good with Pinks they ought to have been planted out six months ago. They should be established in the beds before the winter frosts set in. This has not been a good winter for them; even the best growers complain of many losses, but out of three beds here planted in October not a single plant has failed, except one unhealthy plant put out in spring; they are now making vigorous growth. If Pinks are planted late the lacing will be imperfect. Carnations and Picotees must be wintered in frames in small pots, so that it is quite necessary to plant in spring. They must be planted out and repotted before they make much growth. Ours were done early in April. The pots may be placed out of doors now. The Auriculas are now in full beauty. As soon as the trusses open they are removed to a north aspect, and the colder is the weather will they last all the longer in beauty. Some of the trusses have been out nearly a month. The flowers are shaded from bright sunshine.

Roses are now starting into growth, and so far the frost has not injured any of the young growths, but the bud worm is busy and must be picked out with a needle, which is the most useful appliance for this purpose. Some of the more tender sorts on the walls have become infested with mildew, and had to be dusted with flowers of sulphur.—J. DOUGLAS.

TRADE CATALOGUE RECEIVED.

John Laing, Forest Hill, London.—*Catalogue of Stove and Greenhouse Plants, Florists' Flowers, Roses, &c.*

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

JERSEY.—May 5th, Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

BATH.—May 12th, September 1st and 2nd. Mr. B. Pearson, 13, Milsom Street, Sec.

BLACKBURN.—May 17th, 18th, and 19th. Mr. W. Ditchfield, Hon. Sec.
CRYSTAL PALACE COMPANY.—Flower Show, May 29th; Rose Show, June 19th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.
COVENTRY.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.
LEEDS.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leede, Sec.
BURTON-UPON-TRENT.—June 16th. Mr. Wm. Shave, Bond Street, Sec.
GLASGOW.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.
FAREHAM.—June 23rd. Mr. H Smith, Sec.
EXETER (Rose Show).—June 25th. Mr. J. N. Gray, Queen Street Chambers, Hon. Sec.
WISBEACH.—June 30th. Mr. C. Parker, Hon. Sec.
MAIDSTONE.—(Roses), June 30th, at Vinters Park. H. Benstead, Esq., Hon Sec., Rose Club, Mill Street, Maidstone.
SPALDING.—July 1st and 2nd. Mr. G. F. Barrell, Hon. Sec.
SOUTHGATE.—July 3rd. John Miles, Esq., Hon. Sec., Southgate, N.
DURHAM AND NORTHUMBERLAND.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.
KILSBY.—July 8th. Sec., Mr. C. E. Bracebridge.
OXFORD (Roses).—July 9th. Mr. C. R. Ridley, Hon. Sec.
NOTTINGHAM.—Rose Show, &c., July 9th and 10th. Apply to Alfred Kirk, Municipal Offices, Nottingham.
HEWORTH.—July 14th. Mr. R. H. Feltoe, Heworth, York, Hon.-Sec.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

VINES MILDEWED (*A Gardener*).—We cannot, by the data you give us account for the appearance of the mildew, though it may arise from the imperfect state of the drainage, causing the border to be wet and the roots in an inactive state. We, however, think the ventilation must have been defective, and the moisture maintained too great. The remedy is, as you no doubt are aware, to dust the infested parts with flowers of sulphur. Before another season the border should be examined, and if the drainage be defective it should be rectified. The shanking is confirmative of the border being in an unsuitable state for the Vine roots.

NEAPOLITAN VIOLETS TURNING SINGLE (*Carolus*).—The late blooms of plants being comparatively small and apparently single-flowered is only what may be expected by exhaustion of the plants. The plants ought to be hardened off, the lights removed, and rooted suckers planted in a border of rich soil in an open situation (though if shaded from midday sun all the better), in rows a foot apart, and the plants 9 inches asunder in the rows. They should be well watered during dry weather, keep all runners removed, and banish weeds. Remove the plants with balls to a frame at the close of September. Giant is a form of the Russian, being a stronger grower, and the flowers have longer footstalks. Its season for frames is in winter and spring up to April. Treat it the same as the Neapolitan. In addition to frames you should have beds of Violets outside, which form a good succession; in fact, we have them from September to May inclusive.

VIOLAS FOR SPRING BEDDING (*L. L.*).—Of Violas, which you may raise from seed, the best are V. cornuta Blue Bell (violet), V. cornuta alba (white), and V. lutea grandiflora major (golden yellow). Blue Bell is the darkest we know; if you wish for a paler colour, V. cornuta Perfection is paler and very good, but is not so early as the preceding. Pansies for your purpose are Cliveden Purple, Cliveden Yellow, and Cliveden White; the Cliveden Blue does not perfect seed. The blackest variety is probably Black King.

USES OF HEATED PIT (*A Constant Reader*).—The pit would at this season be most profitably employed in growing Cucumbers and Melons, and in winter it would, we presume, be employed for wintering bedding-out plants, which would be cleared out by May. The plants would, if you can command a sale, be profitable, and is the best use that could be made of it for winter, whilst Cucumbers and Melons, especially the former, would also be a source of profit in the summer; but you will have to ascertain what is in demand, and produce a supply accordingly.

INSECT ON CUCUMBER LEAVES (*Howard*).—There were no insects in the box, but the leaves show beyond a doubt that they have been severely attacked by red spider. Flowers of sulphur sprinkled on the hot-water pipes, or dusted over the leaves, and mixed with the whitewash, will be the proper remedy.

INSECTS ON BROCCOLI ROOT (*Chepstow*).—The Broccoli is very severely club-rooted, and the white insects are Acari, which subsist on the diseased part. There would be no Acari if the root was not clubbed. To avoid club-root do not grow any of the Cabbage tribe on the same plot in two following years, either as a seed bed or to grow for cutting.

GRAPES RUSTED (*H. L. C.*).—The cause of rust is much disputed; but we are quite satisfied that it is caused by the Grapes whilst young being grown in a temperature too high, and then exposed to currents of cold air. It is not infectious, and there is no remedy. A lower temperature and more careful ventilation will prevent the occurrence.

VINE RODS BREAKING IRREGULARLY (*J. M. K.*).—Some of the rods breaking and others remaining dormant demonstrate that the roots do not supply sufficient sap. They are in an outside border, and the exceptionally cold and long-continued winter has rendered them inactive. If the border were covered with fermenting hot stable manure, it might now stimulate them. We advise you next winter to have the border mulched, and over the mulch to place a tarpaulin or other rainproof covering.

SOWING GERANIUM SEED (*Triceps*).—What you call "the husk," we conclude is the aril, which surmounts every Pelargonium (Geranium) seed. Do not pull it off, but insert every seed with the aril upmost, and let it project above the surface of the soil with which you cover the seed.

CORK (*Jersey*).—Write to the Company. Their offices are at 23, Upper Thames Street, London, E.C.

CUTTINGS DECAYING (*W. C. and S.*).—By a careful examination of the soil and a perusal of your case as stated, we conclude that the fault is not in the soil or structure. We believe if you water less frequently and more thoroughly, avoiding mere sprinklings, and a close atmosphere, that you will find a remedy for the evil of which you complain. Fungus is not the cause but the effect of the decay. We are confirmed in this view by a gardener who has called at our office and who has frequently had plants from you. He says you "send him good plants, but the roots are too dry at the bottom of the pots, and too wet near the surface."

MELONS IN GREENHOUSE (*R. T. W.*).—Take up the plants without stopping to within 9 inches of the top of the trellis, and then take out the point of each plant. The plants will put out laterals as they grow, and upon these the fruit will be produced With due care in fertilising the flowers, and stopping the laterals two joints beyond the fruit, you will be able to secure sufficient fruit on each plant. The plants should be 2 feet to 2 feet 6 inches apart.

STOPPING VINE SHOOTS (*H. A. P.*).—Trained on the spur system the shoots should be 15 inches to 18 inches distance apart on opposite sides of the rod, so that the spurs will on both sides of the rod be the distance named apart. Shoots not fruiting should be stopped at the sixth leaf, and to one leaf afterwards throughout the season, and fruitful shoots be pinched at one or two joints beyond the bunch.

FERTILISING (*Idem*).—It is done by applying the pollen of one plant to another of the same race, its anthers having previously been removed. A pair of sharp-pointed scissors for the removal of the anthers, and a camel-hair pencil for the application of the pollen, are all the instruments required. Place the pollen of the fertilising flower upon the stigma of the seed-bearing one, and enclose in a gauze bag to keep off bees and insects. It is a simple operation, giving very often curious and always interesting results.

LIQUID MANURE FOR GREENHOUSE PLANTS (*Idem*).—Horse droppings make a good liquid manure, one peck to twenty gallons of water; and 1 lb. of guano, or one peck of fresh cow dung to the same quantity of water in each case, are also good liquid manures for softwooded greenhouse plants, or all plants except those requiring peat soil. See answer to "*Timepiece*" respecting the Geraniums. Your plants show traces of thrips. Fumigate when the foliage is dry.

GERANIUMS LEAVES SPOTTED (*Timepiece*).—The leaves are suffering from what is known as "the spot," arising in most cases from too close and moist atmosphere at night, which causes the deposition of moisture upon the leaves, and the sun falling upon those whilst wet heats the water and scalds the leaves. It usually occurs in a season like the present—long cold and dull, and suddenly changing to bright days. The only remedy is to admit air more freely, and especially in the early part of the day, leaving on a little at night so as to prevent the condensation of moisture.

GERANIUM LUCIUS.—"If '*C. R.*' can find no person to supply him nearer from your columns, Mr. Cannell of Woolwich, or Mr. Potten of Sissinghurst, Kent, have it in stock.—AGE."

DETERRING RABBITS (*J. H.*).—As a wire fence is inadmissible for excluding Rabbits from your flower beds, we know of but one other remedy—a little dog chained to a kennel near them. Soot would not protect the flowers.

NAMES OF PLANTS (*J. G. S. and Ten-years Subscriber*).—Your specimens are only leaves, and we cannot name from them. (*W. J. H.*).—1, Abutilon Thompsoni, var. marmoratum; 2, Silene sp.; 3, Browallia elata. (*C. B.*).—1, Sparmannia africana; 2, Acacia sp.; 3, Styrax sp. (*Mary*).—Specimens unsatisfactory; 1, Saxifraga crassifolia; 3, S. sarmentosa? 2, Berberis sp.; 4, Thuja occidentalis (Arbor-Vitæ). (*S. P.*).—1, Eriostemon salicifolium; 2, Ceterach officinarum; 3, Asplenium trichomanes. (*W. C.*).—6, Hibbertia volubilis; 1, Adiantum reniforme; 2, A. æthiopicum; 4, A. hispidulum; 3, Cystopteris fragilis; 5, Selaginella Martensii. (*G. H.*).—Both indeterminable from specimens sent; the Moss is a Hypnum; the flower may be Podophyllum. (*Robert*).—1, Prunus serotina; 2, Epimedium alpinum; 3, Saxifraga crassifolia? (no leaves); 4, Cereus speciosissimus. (*A Constant Reader, Sherborne*).—Cydonia japonica. It is not unusual for the flowers to vary from deep to pale rose colour.

POULTRY, BEE, AND PIGEON CHRONICLE.

PROFIT FROM EXHIBITION POULTRY.

WE read the other day in the *Pall Mall Gazette* a touching account of a poultry-yard. The writer was one who had heard of the glorious *coleur-de-rose*-bathed accounts of eggs and chickens bringing-in a marvellous profit. He expected to do likewise, but his airy castles were soon crushed, and his eggs cost him 2½*d.* more each than he could have bought them for at a shop. His failing so utterly may be accounted for by want of ordinary practical knowledge of poultry; for this he seemed to lack, as poultry kept simply for eggs and table birds should pay handsomely. The absurdity of expecting enormous profits, however, has been so often shown up, that we will only speak a word on the profits from exhibition poultry.

In this branch, again, huge sums are supposed to be made annually. We know of one fairly successful amateur who just pays his way, and yet he is considered to be rapidly becoming a young Crœsus. The uninitiated hear of birds realising large prices, of good egg sales, and many money prizes, but they have no idea of the very heavy expenditure. Entry fees, food, attendants, and carriage swallow-up most of the profits, and

leave ordinarily but a poor balance. There are, however, some yards which do yield a good profit, and many of these, moreover, are owned by gentlemen amateurs who are glad to ride a favourite hobby, and make it profitable as well. We are convinced from experience that for a yard of exhibition birds to be really profitable it must be entirely under the owner's personal supervision and management, or that of a skilful and experienced manager. Such managers, however, are few. We could hardly name a dozen whom we should care to have to superintend our own yards, and so amateurs who really mean to make exhibiting pay must work themselves.

We have from time to time seen interesting accounts of the profits of small yards where the birds have been kept entirely for eggs and table birds. These accounts have always been of very small establishments, where the profit or loss could only be limited, and we have consequently procured the account book of a successful exhibitor for twelve months, who has kindly given us permission to make any use of it, and we cannot help thinking that the results will be alike interesting to all fanciers. The accounts we have before us are those of 1874. They include every penny spent or received during that year. The gentleman whose accounts they are exhibits three breeds; one of the larger varieties, one for variety classes, and one of Bantams. To prevent recognition we will change the names of the breeds he actually keeps, and call them Buff Cochins, Leghorns, and Black Bantams. The gentleman keeps a young man of about eighteen to feed, clean out the houses, and do all such-like work, he himself superintending the matiug, change of foods, and selection for exhibition, &c. We may safely call him a member of the successful class of exhibitors, and one who has worked hard, and does work hard with his hobby.

First, then, for expenditure. We find the total sum spent during the year for entry fees at shows was £48 15*s.* 6*d.*; for labour and wages for the twelve months, £37 16*s.* 9*d.*; the total sum for railway carriage, £32 10*s.* 6*d.*; the bills for foods of all kinds, £36 5*s.* 6*d.*; birds and eggs were purchased to the value of £69 18*s.*; the sum paid for advertisements was £5 17*s.* 6*d.*; and sundries, such as catalogues, telegrams, egg boxes, string, nails, baskets, &c., came to £5 14*s.* 9*d.* These several amounts make the total expenditure £236 18*s.* 6*d.* We must notice that nothing is charged for the exhibitor's own expenses to and at shows, but in the majority of the cases he did not attend, and the birds were sent by train as parcels. The servant did not accompany the birds in any case. We find, too, no charges for rent, as the runs for the birds were wood and meadow land, which would have to be in use apart from keeping the poultry.

We will now turn to the receipts. The amounts won in cups and money prizes amounted to the goodly sum of £121 9*s.* The sale of eggs for sitting and domestic purposes came to £42 9*s.* 3*d.*, and the sale of birds to £190 18*s.* A few extra receipts in the shape of birds killed for table, &c., came to £1 17*s.* 2*d.* These sums added together give us £356 13*s.* 5*d*, taking from which sum £236 18*s.* 6*d.* we find the balance of £119 14*s.* 11*d.* to the good.

Examining the exhibition department even more minutely we find the carriage and entry fees come to £81 6*s.*, and the winnings to £121 9*s.*: hence we can deduce £40 3*s.* was the sum actually made in exhibiting. Of course in such yards the profits come much more from the sale of birds through their winnings than in the actual amount of prize money. In this case, however, the exhibitor himself spent £69 18*s.* on birds, for although he is one of many years' standing, birds came into the market which he thought it advisable to procure, or else his profits would have been much larger, for it is quite out of the way for anything like such an expenditure on birds being made. We must also say we find no mention of losses by death of valuable birds. We have simply made out the gross receipts and expenditure for twelve consecutive months.

Thus much, then, for the £ *s.* *d.* department of a fairly successful exhibition yard of poultry. We do not pretend that all can do the same, or that even much larger profits may not be made. We picked out this gentleman as representing an ordinary successful exhibitor, and give his statements. We ourselves consider them highly satisfactory, and we are convinced many who do not now find their poultry profitable can make them pay handsomely, but it cannot be done without a knowledge of poultry management, hard work, and zealous watchfulness.

We know of one gentleman who is up at 6.30 A.M. throughout all the early months of the year that he may feel sure the "babies" are being attended to and fed at early times. It is not only in poultry affairs, but in every other pursuit, that we have to be always looking out not to be left behind.—W.

Bees in Somersetshire.—I think the coming season here is a very promising one where the bees have been managed properly. I have six hives, very strong; three of them have already commenced in the super glasses. I had twelve hives last autumn, which I united, making six of the strongest I ever saw. I took in supers last season 296 lbs. of very fine honey, most of which I sold for 1*s.* 6*d.* per lb. I found out a very simple and effectual mode of uniting hives, which I will communicate to you later in the season. I have taken a great interest in bees for the last ten years, and the results are well known in this locality.—Robert Manfield, *Wellington.*

EGG BUYERS AND SELLERS.

A correspondent in your last issue having narrated his unfortunate experience in dealing with sellers of eggs for hatching, would you kindly allow me to tell mine, which shows that there are some sellers who are as much disappointed when a sitting of eggs turns out badly as the buyers can be? Last year I asked for two sittings of Brahma eggs from a famous breeder. I received them at different times, as I was too impatient to wait to have them all at once. Out of the first sitting I had only two cockerels, and out of the second I had four cockerels. Two of these last died young, having been weak chickens which I had to assist out of the shell. I then asked for another sitting, and I received them with a request that the question of payment should be delayed till the result should be known. Out of this sitting I had two cockerels and four pullets, which I considered very good, as the eggs had travelled over five hundred miles, and, therefore, without more ado I sent the vendor a post-office order for the full price of the eggs. Thus I had ten chickens out of my three sittings of eggs, for the two that died can hardly be counted, as they would never have hatched had I not assisted them. All these ten chickens turned out to be rather more than fairly good. I exhibited some of them on two different occasions, of course all in the same class, and I gained one second prize, two high commendations, and one commendation. The first prize on one occasion going to birds of my own breeding, and on the other to birds from the other end of the kingdom. These ten chickens cost me £4 10*s.* including the carriage of the eggs, and I do not believe I could have bought one of the cocks for the money.

This year again I wrote to a gentleman as soon as I saw his advertisement in your columns, and asked him to book me for a sitting of eggs to be sent to me in the end of March or beginning of April. He answered that he could send me the eggs at that time or sooner if I liked, and he thought they would prove fertile. I had doubts about the advisability of having them sooner than the time I had fixed, as I had experienced the general difficulty of obtaining eggs to hatch early this season. However, the desire of securing early chickens prevailed, and I thought that I would, perhaps, be more successful with eggs coming from a warmer climate than I had been with my own, so I had my sitting of eggs early in March. In due time one and only one chicken made its appearance. I wrote for another sitting, and asked if I would have to pay full price for it, considering my ill-luck with the first. The vendor answered that he was truly sorry to hear of such a poor result from my first sitting, and sent me another at half price, and promised that if the result proved no better he would give me another sitting gratis. The second sitting is now under the hen, and I do not yet know what the result may be, but I am sure that if it is not good the vendor will be as much disappointed as I shall be.

I have no doubt there are people who advertise worthless eggs at considerable prices, but I do not think that all who do so do it knowingly. A man may undeservedly be awarded a prize at a show, or, perhaps, a first prize at some small local show, and with some people a first prize is always a first prize whether gained at the Crystal Palace or at the local parish show, and elated by his success he may wish to give others the opportunity of obtaining his prize strain, and therefore he advertises eggs. Purchasers of such eggs may expect to meet with disappointment, and however well the eggs may hatch, they will probably not have one good chicken. What is worth doing is worth doing well, and for all the difference between the price of the best eggs and ordinary eggs, it is better to go at once to the most successful breeders of the kind that you want. Successful breeders have a reputation to sustain, and I think they have a kindly feeling towards others who follow the same fancy, and they are willing to assist them in any way they can. At all events that is my experience.

It is not fair to accuse a vendor of eggs of dishonesty because a sitting of eggs does not hatch as many chickens as the purchaser expects. If every one hatched either the price of eggs would be considerably raised, or else the value of prize poultry would fall very much.—Geo. Wilson.

ACCRINGTON SHOW OF POULTRY, &c.

The annual meeting of the Accrington Agricultural Society came off on the 22nd inst. The entries in all sections of which we write were very good, as will always be the case where such substantial prizes are offered—viz., £2, £1, and 10*s.* for poultry, and £1 and 10*s.* for Pigeons and Rabbits.

In single *Game* cocks Mr. Matthew won the cup for Game with his well-known Brown Red, the second also a Brown Red, and withal a good bird. Mr. Harley showed an excellent Black Red,

which was, however, only commended. In Game cocks, any other colour, Messrs. Walton won with an excellent Pile, the second and third being Duckwings, both good and well shown. In Red Game hens the first was the one first at Great Harwood, again beating the same bird. All were Brown Reds. In the following class a Pile was first, and Duckwings second and third. The local Game cocks were better than we have usually seen them here. Many of the best *Dorkings* were bad on the feet, but the winners were good, the first and third Dark, and second Silver-Greys. *Cochins* were very good, Buffs winning. In the next class the first were Partridge, as also the third; the second, which were White, were a capital pen. *Spanish* were a very even class, although the winners stood out from the others. In *Brahmas* the winners were of the Dark variety. In *Hamburghs*, Gold-pencils, the second-prize cock was by far the best, but the pullet in the first-prize pen was far a-head of the second. Silver-pencils were a good lot, the cocks being particularly good in marking. Gold-spangles were good, the hens in the prize pens being particularly fine in all respects. Silver-spangles were a fair lot, some of the cocks being specially well marked and white; the Blacks were but a moderate lot. In *French* fowls the first were Crêve-Cœurs, second La Flèche, and third Houdans; in the Variety class the prize went to Polish and Cuckoo Cochins. In the Game *Bantam* classes Mr. Hall left little for the rest of the exhibitors, winning a cup and first in three of the classes. These classes were much better than we have generally seen them here. In Red hens Mr. Sharples won first with a model hen, not one of the smallest, but in every other respect perfect, and in the following class all the winners were Piles. In Bantams, any other variety, the winners were Blacks. The entries in *Turkeys* and *Ducks* were not large but the birds were good, Mr. Walker winning most of the prizes.

Pigeons were shown in pairs except the Carriers and Ponters. In *Carrier* cocks the first was a Black, and second and third Duns, one of the best birds being so severely trimmed as to destroy its chance of a prize. In hens the first and third were Duns, and second Black. The third shown by Mr. Walker was by far the best, but not at all in show condition. In *Tumblers*, Mr. Yardley won with a grand pair of Almonds. These birds were both rich in colour and beautifully broken in feather. *Barbs* were Black, and Reds second, the latter pen containing the cock first at Harwood, but the hen was too young. The third, also Black, were good. English *Owls* though numerous were not first-rate, although the winners were pretty good. First and second Blue, and third Silvers. In *Pouter* cocks the first was a Blue good in all points, second White, and third Red; but the hens were superior to the cocks. The first-prize Blue being quite a model, not alone in measurement, but also in style, girth, and carriage. The second, a Blue, lost only in girth; the third being White. *Fantails* were good, but the pens too small to show two birds. In *Turbits* Blues were first, Silvers with shell crowns second, and Yellows third. *Dragoons* as a class were not as good as we expected to find, but the first-prize pair of Blues were perfection, in our opinion, in all respects; the second were Grizzles, very good in all points; and third Blues, but the latter were a little too flat on the skull. *Trumpeters* were very poor. In *Jacobins* the first were Reds, good but rather large; second a pretty good pair of Yellows; and third Reds. In *Nuns* the first and second were Blacks, and third Reds. *Antwerps* were a good class, but there were some pairs of cocks shown. The winners, first Silver Duns; second Red Chequers; and third Blue Chequers, all Short-faces and very good. In *Magpies* the first were Red, as also the third, the second being Blacks. In the Variety class the prizes were awarded as follows:—First Fairy Swallows, second Spangled Ice, and third Pigmy Pouters. There was no Selling class for Pigeons.

Lop-eared Rabbits were not a large entry, the first and second stood as at Harwood a week ago—viz, doe Black-and-white, 22½ by 4⅝; second, doe, Tortoiseshell, 21½ by 4¾; third, Fawn buck, 21½ by 3¾. Angoras were very good in all respects. In Himalayans was one of the best seen for some time, the class being altogether good. Silver-Greys were a fair lot, Miss Mortimer winning by size alone over Mr. Hallas's excellent young Rabbit. The Selling class was large and good, Lops winning first and second, and a Silver-Grey third, and being in the list at the low price of 10*s.* each were soon picked up.

Game.—*Black or Brown Red*—*Cock.*—Cup, S. Matthew, Stowmarket 2, R. Ashley, Nantwich. 3, J. Cock, Worcester. *hc*, R. Garnett, Wyreside; J. Fletcher, Stonesclough; W. Ormerod, Todmorden. *c*, W. Watson, Nantwich; D. Harley, Edinburgh; A. Sngden, Cleckheaton. *Hen.*—1, W. Ormerod. 2 and 3, C. W. Brierley, Middleton. *hc*, R. Baker, Todmorden; J. F. Walton, Rawtenstall (2)

Game.—*Any colour.*—*Cock*—1, J. F. Walton. 2, J. A. & H. H. Staveley, Driffield. 3, E. Winwood, Worcester. *Hen.*—1, J. F. Walton. 2, S. Matthew. 3, J Fletcher.

Game.—*Cock.*—*Within three miles of Accrington.*—1, J. Wood, Accrington. 2, J. Greenhalgh, Huncoat. 3, S. Cooper, Oswaldtwistle.

Dorkings.—1 and 2, J. Walker, Rochdale. 3, W. H. Crabtree, Levenshulme. *hc*, W. Clough, Farby, Leeds; W. H. King, Rochdale.

Cochins—*Buff or Cinnamon*—1, J. Walker. 2, W. H Crabtree. 3 and *vhc*, W. A. Taylor, Manchester. *hc*, Mrs. Allsopp, Worcester (2); H. Tomlinson, Birmingham; J. F. Clarkson, jun., Preston; S. R. Harris, St. Day. *Partridge and White.*—1 and 3, W. A Taylor. 2, H. Beldon, Bingley. *hc*, H. Lacy, Hebden Bridge; J. F. Clarkson, jun.; J. Walker.

Spanish—*Black*—1, H. Beldon. 2 and 3, Mrs. Allsopp. *hc*, S. L. Edwards, Tarporley; J Thresh, Bradford; J. Smalley, Livesey.

Brahmas.—1 and 2, T. F Ansdell St Helens. 3, W. Whiteley, Sheffield. *hc*, J. F. Smith, Sheffield; W. H. Crabtree (2).

Hamburghs.—*Golden pencilled.*—1, G. & J. Duckworth, Church. 2, H. Beldon. 3, C Judson *vhc*, H. Beldon; H. Pickles, Earby; G. & J. Duckworth. *Silver pencilled*—1 and 2, H Beldon. 3, H. Pickles.

Hamburghs.—*Golden-spangled*—1, G. & J Duckworth. 2, H. Beldon. 3, T. Dean, Keighley. *hc*, N Marlor, Denton; T. Blakeman, Tetlenhall; H. Pickles; G. & J. Duckworth. *Silver-spangled.*—1, J. Fielding, Newchurch. 2 J. Fielden, Newchurch. 3, Ashton & Booth, Broadbottom, *hc*, J. H. Howe, Denton; H. Beldon (2).

Hamburghs.—*Black*—1, W. Rentley, Holmfirth. 2, H. Beldon. 3, Stott and Booth, Bury *hc*, W. Wilson, Waterfoot; H. Pickles.

French.—1, W. H. Crabtree. 2, E. Walton, Rawtenstall. 3, W. Whitworth, jun, Longsight. *hc*, C. M. Saunders, Lancaster; R. J. G. B. Knight, Ripley.

Any other Variety—1 and 2, H Beldon. 3, J. Walker, Rochdale. *hc*, T. Aspden; A. & W. H. Silvester, Sheffield; Rev. A. G. Brooke, Shrewsbury.

Any Variety except Game and Game Bantams.—*Three miles of Accrington.*—1 and 3, T Aspden. 2, G & J. Duckworth.

Selling Class.—1 and 2, R Corless, Broughton. 3, A. Bamford, Middleton. *hc*, J. F. Walton (2). *c*, J. Powell, Bradford.

Game Bantams.—*Black or Brown Red.*—*Cock.*—Cup, G. Hall, Kendal. 2, A. Sugden, Cleckheaton. 3, W. F. Addie, Preston. *hc*, J. Saul, Preston; J. B. Fletcher (2); T. Barker, Burnley; G. Hall; W. F. Addie; E. Walton. *Hen.*—1, T. Sharples, Rawtenstall. 2, A. Sugden. 3, W. F. Addie. *vhc*, E. Walton. *hc*, J. R. Fletcher (2); W. F. Addie.

Game Bantams—*Any other colour.*—*Cock.*—1, G. Hall. 2, Bellingham & Gill, Burnley. 3, T. Barker. *Hen.*—1 and 2, Bellingham & Gill. 3, T Barker.

Game Bantam.—*Cock.*—*Within three miles of Accrington.*—1, Whittaker and Birtwistle, Haslingden. 2, G. Riley, Baxenden. 3, G. Anderton, accrington. *hc*, G. Anderton; T. A Mylrea, Church.

Bantams—*Any variety except Game*—1, Milner & Beanland, Keighley. 2, H. Beldon. 3, Bower & Horsfall, Harden, Bingley. *hc*, R. H. Ashton, Mottram; H. B. Smith, Preston.

Turkeys—1 and 2, J Walker.

Geese—1 and 2, J. Walker. 3, J. Christie, jun., Clayton-le-Moors.

Ducks.—*Aylesbury.*—1 and 2, J. Walker. 3, C. Holt, Rochdale. *hc*, C. Holt; J. Hedges, Aylesbury. *c*, J. Hedges *Rouen.*—1, J. Walker. 2 and 3, J. Wakefield, Newton-le-Willows. *Any other variety.*—1, A. & W. H. Silvester. 2 and 3, H. B. Smith. *hc*, H. B. Smith; J. Walker.

PIGEONS.

Carriers—*Cock*—1 and 2, E. Horner, Harewood. 3, J. Chadwick, Bolton. *hc*, H. Yardley, Birmingham; J. Walker, Rochdale. *c*, J. Stanley, Blackburn (2); J. Chadwick. *Hen*—1, H Yardley. 2, J. Chadwick. 3, J. Walker. *vhc*, F. Raddeley, Sale *hc*, J Stanley (2).

Tumblers—1, H. Yardley. 2, A & W. H. Silvester, Sheffield. 3, T. & W. Oddie, Brierfield. *vhc*, W. Boydone, Dunse. *hc*, E. Horner; J. Gardner, Preston; H. Yardley (2). *c*, A. & W. H. Silvester, Sheffield.

Barbs.—1, E. Horner. 2, R. White, Manchester. 3, J Stanley.

Owls.—1, J. Richmond, Oswaldtwistle 2, T. & W. Oddie. 3, R. White, Manchester. *hc*, S Lawson, Preston; Rev. A. G Brooke, Shrewsbury. *c*, J. Holden, Rochdale; A. Warburton, Haslingden; H. Yardley.

Pouter or Croppea.—*Cock*—1, W. Nottage, Northampton 2, Mrs Ladd, Calne. 3, E. Horner *hc*, E. Horner; P. R Spencer, Hereford; J. Richmond, Oswaldtwistle; L. & W. Watkin, Northampton. *c*, W. A. P. Montgomery, Belfast; Mrs Ladd. *Hen.*—1, W. Nottage. 2, E. Horner. 3, Mrs. Ladd. *vhc*, L. & W. Watkin. *hc*, A Thewlis, Meltham; E Horner; L. & W. Watkin.

Fantails.—1, W. J. Warhurst, Staleybridge. 2, J. F. Loveraidge, Newark. 3, E. Horner. *c*, S. Lawson, Preston.

Turbits.—1, T. S. Stephenson, Beverley. 2, W Boydone, Dunae. 3, E. Horner. *hc*, H Yardley; E. Horner; J. Gardner, Preston. *c*, M. Stackforth, Croston; R. White; J. Gardner.

Dragoons.—1 and 3, R. Woods, Mansfield. 2, J. Holland, Cheetham Hill. *vhc*, J. Stuttard, Colne; H. Yardley. *hc* J. Stuttard; R. White; E. Horner; J. Chadwick, Bolton. *c*, J. Holland; J. Chadwick.

Trumpeters.—1, J. Gardner, Preston. 2, Wells & Sherwin, Ripon. 2, T. S. Stephenson.

Jacobins.—1, J. Powell, Bradford. 2, W Boydone. 3, S. Lawson, Preston. *hc*, S. Lawson; J Richmond; E. Horner; J. Gardner. *c*, A. Smith, Halifax.

Nuns—1, E. Horner. 2 and 3, Rev. A. G. Brooke.

JACOBIN.

Mr. E. E. M. Royds, the President of the Northern Counties Columbarian Society, read the following highly interesting paper at one of its recent meetings:—

"Doubtless you are all aware my only hobby for some time has been the Jacobin. Since the year when I was so successful at Bingley Hall I have kept nothing but Jacobins, and endeavoured, by giving as much of my time as business would permit, to raising this beautiful variety of Pigeon to the standard it has now reached. The Jacobin (Columba cypria cucullata) is mentioned in the second volume of 'Ornithology of Ulysses Aldrovandus,' 1600, published at Bologna:—'There are two kinds—one hooded, the other smooth heads, and some have

naked and others feathered feet; the hoods are erect and large.' With part of this I agree, but I certainly do not want any erect hoods; for the closer the feathers fit the head the better, and the more the bird is valued; at the same time, though, there are other properties, and very important ones, to be looked for.

"The Jacobin is well known over England, France, and Germany, and derives its name from its having a clear white head, enveloped, as it were, in a hood of dark feathers, resembling the shaven crown of a monk partially covered with a cowl. The German name, 'Zopf or Perrücke Taube,' signifies having a wig; and Willughby, in his 'Ornithology,' 1678, says they are called by the Low Dutch 'cappers,' for reasons I have mentioned above. But perhaps the best treatise on the Jacobin is Moore, 1735, who says in his 'Columbarium':—'The Jacobin is ofttime the smallest of all Pigeons, and the smaller still the better.' All fanciers must agree with me that ten years ago the Jacobin was very poorly represented; but latterly no bird has improved so much (except, perhaps, the Trumpeter), and now many almost perfect specimens are to be found. Its general colours are black, red, and yellow; but at large shows very often good whites are to be found. In whites, though we lose a great point—viz., colour, yet a really good white with a pearl eye is not to be met every day. The head, tail, and flight

Fig. 82.—The Jacobin.

feathers of a Jacobin should in all cases be white. There are Pigeons occasionally seen, and are called Jacobins, which are one colour, and I have known instances of all black and all blue. The latter I have kept, and bred blue birds from them with white properties, but never raised anything fit for the exhibition.

"With regard to the number of white flight feathers, it is a disputed point; and, as they say in Lancashire, different folks have different opinions; for my own part, I am satisfied with seven or eight white flights in each wing, though there are fanciers that say a perfect specimen should have ten. This, however, is not an important point; at the same time it must be remembered I am not an advocate for a bird short of white flights. To run through the principal points of a really good bird is more easily done on paper than by breeding, though a well-known fancier and dealer in London—in fact, I have heard him designated a Pigeon without feathers—tells me he finds Jacobins as easy to breed as weeds in his garden, and can rear annually any amount of good birds. The beak should be short and rather stout, with a small wattle, and in many cases you will find the lower mandible dark; this is not a disqualification, though white is preferable. The eye in all cases must be pearl. I have had many good specimens spoilt with either a 'gravel' or a 'bull' eye, and either is in my idea a great fault, and a very unpleasant thing to get into your loft, as it may take years to breed out. The head should be short and well enveloped at the back with closely-arranged feathers of the same colour as the body of the bird, which gives the bird an appearance of having the feathers glued on to the skull, so close should they fit; joining this arrangement of feathers, which is called the hood, should be another range of feathers, reaching down to the shoulders, or rather they should go further, and encroach more to the breast of the bird, forming a chain, or, as the Dutch call it, 'the cravat.' These feathers should be long and close, and the more even and close they are set the more is the bird esteemed. I think the hood and chain are almost the principal points of the head, and give to the bird a very strong resemblance to the portraits of good Queen Bess. In getting this chain we must not lose sight of size, for the larger the bird the heavier ought to be the chain and hood; and I must again remind you that the Jacobin as a Toy, and one of our prettiest Toys, should be small, and the smaller it is the better; in fact, as Mayor in his treatise says, it should be very little larger than a Tumbler. At the bottom of the chain or mane we come to

another point of beauty—viz., the rose, a centre spot of white down, caused by the feathers turning different ways, and with this point, which is a great one, we complete the characteristics of a true Jacobin—viz., the hood-chain, mane, and rose. In olden times a good Jacobin and a really valuable bird was proved when, by taking hold of the bill and drawing the head backwards, the two sides of the chain lap over each other, but this is unnecessary in our present age; and I know of many birds in which the chain not only unites, but crosses over while loose in the pen, and it is in these birds you find the true 'hog mane' so much sought for, instead of the chain going all around the neck and head of the bird, having a roundness at the back instead of a sharp peak, caused by the feathers meeting from either side. Many fanciers want a good specimen to have white thighs, but this I do not agree with, as then the Jacobin carries too much of baldpate; and while referring to them I must say, in regard to the head of the Jacobin, there must be no white feathers under the bill, and on no account so low cut as the baldheaded Tumbler of the present day. In Red Jacobins we frequently find a slaty-bluish-coloured thigh; but I prefer the thighs being of the same sound colour as the body of the bird. Now and then we come across a good bird with white thighs; but at the same time there is a tendency to be low cut in the head, which is a great fault. In the Jacobin I notice many peculiarities of carriage, some literally standing on their tails. This, of course, is a fault, and in spite of all your trouble you cannot keep the bird clean; others are lazy, and mope in a corner of a pen until stirred up with a long pole. What I want in a Jacobin is a small tight bird, with its wings slightly drooping, though not *à la* Tumbler, and then I can see as much carriage and style in a Jacobin as Scotty does in a Ponter. I do not call them good nurses, but still I do not use 'feeders,' and can manage to rear a good bird now and then. One thing I have noticed for many years is the pugnacity of White Jacobins, especially in the breeding season; they seem to master the whole loft, and have a special hatred for a red bird.

"In conclusion I must say I am in a great measure indebted to Mr. Esquilant for my knowledge of a Jacobin; he is well known to us all as a great admirer and successful breeder of this very beautiful variety, and from him, many years ago, I purchased a pair of Black Jacobins, which won, I think, first at Birmingham for three years, besides many cups and other prizes. Though these are gone, I have still the strain left, and intend to do my best to keep this very interesting variety a prominent feature in the Northern Counties Columbarian Society."

[The above interesting paper on the Jacobin is extracted from the American "Fanciers' Journal." It is difficult, of course, to say anything new of an old variety of fancy Pigeons, therefore a great deal of the above is, of necessity, familiar to all readers of the old and of new books on Pigeons; but much of interest is added, and Mr. Royds does not seem to me to write quite clearly about the mane of the Jacobin. He speaks of the "chain or mane." For young fanciers I will explain that the chain is on each side of the neck; the mane is at the back of the neck, and is well called by Mr. Esquilant a "hog mane." This I consider a marvellous beauty in the bird. A stiff line of erect feathers with no notch in them, which the birds have that have no mane, to my mind look as if a bit had been cut out of the feathers by a pair of scissors, whereas the maned birds have a vastly superior appearance.

The rose is also another marked beauty, and best seen, I think, in yellow birds, as the under part of the feathers of that colour show better than that of the black, and yellow is a more delicate and tasty colour than red; hence, perhaps, the yellow Jacks ranked first with the old fanciers. There is another thing to be said for the Jacobin, which can also be said for the Black Mottled Tumbler; the better it is to the eye of a fancier the more pleasing it also is to a non-fancier. It is a bird which pleases at once every eye, whereas Pouters, Carriers, Barbs, and Almond Tumblers must have trained and skilled eyes to see their beauties, which very beauties non-fanciers do not see, but actually dislike. The prize Barb, ladies call a horrid red-inflamed-eyed thing; but the more perfect the Jacobin the prettier it is. Give the small head, the pearl eyes, the close hood, the long chain, and the firm upstanding mane, and the sound colour, it is as delightful a bird to one who does not understand fancy Pigeons as to those who know every property.

This is the same with the good black Mottle Tumbler, and the graceful petite Scotch Fantail. The beauty of each is recognised at a glance by all.—WILTSHIRE RECTOR.]

OWL PIGEONS.

How doctors do differ! aye, and some of them are called fighting men too, because they cannot agree with their friends and neighbours in everything; but without those so-called fighting men we should never detect the imperfections we in common desire to discover and to know, and consequently wish to avoid. I have read in our Journal the debate so far on this subject, and agree with "BUBO;" I agree with him in all but one term, and that is "degenerate."

I do not wish to throw cold water on anyone's hobby, very far from it, but I would like to see the various classes of Pigeons placed in their proper light, so far as we can place them, and to bring out clearly the perfections or imperfections of each bird as the case may be, not only to make sure of the purity of the race of birds we keep and fancy, but of the birds worth our keeping, of their true characteristics, and if possible the original history of each race. This is our sole aim, and for which fortunately the columns of our Journal are open to us.

In a word I think the English Owl is a mongrel bird. Did I say it was degenerated I should allow it had fallen from its normal state, become coarse and otherwise changed by some influence or another; but in using the word mongrel I consider it a crossbred bird. No doubt the true Owl has been one of the original parents of the English Owl, the other may have been a small Blue Dovecote Pigeon, and I think by careful selection I could produce thus a good English Owl in two generations, such a bird as would stand well at a show.

In looking over the large classes of English Owls at our shows I rarely see above a pen or two showing the head of the true Owl, and often all the best of them are coarse, large, and cross-bred-looking, some of the best having very little frill or purl; on the other hand the great bulk are long, or as some will have it, pleasant-faced, many of them with the head and features of a common Pigeon. Most judges I think will admit that while judging classes of English Owls the first thing they look for are the birds that come nearest to the African; should they hit upon such a pen there are few, if any, complaints. If colour is to be taken into account that is a different thing, the worst coloured birds may be the best in the class as Owls. So convinced am I that the English Owl is but a mongrel that I should advise it to be replaced by the African, and then breeders will find that they will produce something worth their labour.

It has all along been my belief (it may be called theory) founded on many years' observation and experience, that the varieties of domestic Pigeons are natives of different parts of the world, and from the fact of the African Owl being unique, and so far as we know coming from Africa only, I am still more confirmed in my opinion.

The African Owl is a brave little bird, he will fight for his place in the Pigeon house against both strong and large odds, he is full of life and activity, and withal he is "gentle as a dove."

The White variety is lovely, his face is far beyond pleasantness, and as a bachelor friend once said, "It is just a thing for kissing." Really there is something melancholy in this saying; but never mind, their exceeding smallness, trim figure, and fine mild expression and habit render them at once the Una of the whole Pigeon family.

I do not know why, but pets seem all the more esteemed if little. Well, the African Owl in its normal state is the smallest of all domestic Pigeons, and therefore must and will become the greatest of all pets in Pigeons. At present it is not much known to the public, but I hope to see ere long large classes of them at our shows.

As to the flying powers of this little bird I have had sorry experience, such as causes me to differ from my friend "WILTSHIRE RECTOR." I would not advise my friend to try it, for most likely off goes a five-pound note, or as Mansie Waugh would say, "Like the flash of the setting sun," it may never be seen again. The bird I lost was watched for a day and night, but proved too sharp for the most cunning hunter.

I agree with my friend that this bird breeds in this country, as I have seen young birds in the nest from imported birds, and these young birds seemed quite as fine as the parents. But I differ in regard to the Trumpeter; they may not breed (imported birds) in England, but certainly they do in Scotland. Mr. Ure I know bred last year six or seven birds from one pair of imported birds. The climate may have something to do with this, but if we can acclimatise the Canary so that it will fly at large and build its nest in a hedge in Scotland, surely we can also acclimatise the African Owl or any other Pigeon.—JAMES HUIE.

A CUTTING-OUT EXPEDITION.

A FEW weeks ago a gentleman and neighbour consulted me about a colony of bees which had been located for many years in the wall of his stable, apparently flourishing, but of no utility to anyone, and a natural desire had grown-up that the lodgers should pay some rent; so I promised to pay a visit of inspection and see what could be done.

I found the wall was a double one with a clear space of 6 or 8 inches between, and divided by perpendicular piers at intervals. The bees entered about 10 feet from the ground, through a large gap which, years ago, had been made, and through which the combs had been removed. The bees had then moved further to the right and set-up their establishment again, notwithstanding the inclement east wind which entered the gap. My advice was that the wall should be further opened and the

combs cut out and removed with the bees into a frame hive, and then their old quarters being bricked-up I had no doubt all would go well.

The plan being agreed on I volunteered to undertake the job, which was then adjourned until the hive was ready and the weather a little warmer. This happy conjunction of circumstances having at length occurred, I and my friend Mr. Cheshire, who kindly offered to assist, last Saturday commenced operations. A plucky bricklayer being in attendance duly attired in a bee-veil, the bricks were quickly removed and disclosed three fine combs about 30 inches by 12 each (as well as some odd pieces), the first of which I soon cut out; and while Mr. Cheshire was cutting and fitting it into the frames I sought for the queen among the large living sheet of bees disclosed to view on the second comb, but without success. This was next cut-out and examined on the other side, then the next, and the next, but still no queen was seen—plenty of brood, and an immense number of bees; but, alas! our new Crystal Palace prize hive did not tempt them to stay, for although we kept the combs the bees flew back, and it became evident her majesty remained in her old quarters. Again and again were the bees swept off and the queen sought each few minutes, showing us the number of bees visible was sensibly diminishing, and it became evident they were disappearing under the roof-plate. A slate or two removed disclosed no tidings of the lost bees, and we began to think our operation would result in a lamentable failure, and the large quantity of brood we had already in the hive was in imminent danger of perishing, when a happy thought struck me: If the mountain will not come to Mahomet, Mahomet must go to the mountain! I ran briskly up the ladder, and the full frames being handed up we made a frame hive of the wall by hanging-up the frames in their old quarters, feeling sure the bees would descend and take possession, save the brood, and be handy to remove another day. Then covering all up snug with some garden mats we left them for forty-eight hours' rest.

On my second visit I found the plan perfectly successful. The combs were well covered with the bees, the queen among them, and having quietly placed them in the new hive without disturbance, had the satisfaction of finding not more than half a pint left behind, which ran up to the roof plate as before, and so were obliged to be left. The wall was then quickly bricked-up, leaving a small aperture till to-morrow for the prisoners' exit. The colony we thus obtained was quite equal to a large swarm in May, and being well furnished with brood and combs I have no doubt will thrive. A few pounds of surplus honey was also obtained for use in the house.—JOHN HUNTER, *Eaton Rise, Ealing.*

BRITISH BEE-KEEPERS' ASSOCIATION.—This Association will hold a conversazione at Burlington House, Piccadilly, in the rooms of the Linnean Society, on Wednesday evening May 5th, when the prize schedule of the next show, which is arranged to take place at the Crystal Palace, September 21st, 22nd, and 23rd, will be discussed.

OUR LETTER BOX.

POULTRY-KEEPING ARRANGEMENTS (*T. M. B.*).—There would have been no occasion to give a large price for a Brahma cock unless you wanted a prize bird. Your description of their roosting place is that of a bad one. If your fowls roost on the bricks or stone shelf they will all have cramp, and many die. Two laying boxes will be enough for six or eight hens. They should be 24 inches square, have a bend in front to prevent eggs rolling out, and should be divided by an upright board 12 inches high. They should be well filled with straw, or the eggs will be damaged if laid on stone. The sitting hens must have a separate place. You will only have trouble and disappointment if you let them sit in the laying house. You may keep a cock and five hens in the space you name, but you cannot rear chickens in it. The perches should be within 24 inches of the ground. If your birds persist in roosting on the ground, you must put down some straw; but we believe if you put proper perches they will take to them. Ground oats or barleymeal are the best food, varied with a little Indian meal, and if their run has no grass the birds must have large sods constantly thrown to them.

CANARY NOTES (*Groundsel*)—1. The wish to obtain Canary eggs from fanciers in the like manner that sittings of eggs are obtained from fowl breeders is in "another street" entirely. The breeders of cage birds are not furnished with eggs in the same proportion as fowl breeders, therefore how would it be possible to supply them when the few eggs the Canaries lay over each nest are required for the birds to sit upon? There would be considerable risk in transmitting eggs from England to Ireland, or elsewhere, either by post or otherwise. 2. We never recommend dealers, and for you to become acquainted with the tip-top fanciers in England we should advise you to purchase the catalogues of some of the principal cage-bird exhibitions held. From time to time you will find the announcements of the shows in our advertising columns. 3. As to the price of pairs of Belgians, Norwich, and Scotch Fancies, much depends upon the quality and breed, and likewise the particular periods and circumstances under which a bargain may be struck. It is not an uncommon occurrence for £3 to £5 or more to be paid for a single specimen of a Belgian bird. A pair of Norwich birds of fair breed might be purchased for 25*s.* and upwards. Sometimes exhibition birds realise fabulous prices. We know an instance last season of ten guineas having been paid for a single Norwich bird. Even if you purchase a pair at a somewhat moderate figure, and breed from the same, you will have to study cayenne before you make headway at a show. Scotch Fancy birds, by the same rule as other breeds, vary much in price. 4. It will not matter about the hen Finch being in the same room as the Goldfinch and Canary, which you say are "caged off." If the Goldfinch becomes paired to the Canary hen, the hen Finch will not draw away his affection for his lady-love. By taking a Canary cock away from a hen he was paired to, and placing a Goldfinch to that same hen at the time she was sitting a nest of eggs, you run the risk of having the nest gradually pulled to pieces by the Finch, and possibly the eggs to become destroyed. Goldfinches are very fond of tapping eggs with their sharp beaks. You will be lucky if you escape all this, and the hen you have taken the cock from does not forsake her nest through grief for her first love. May will be early enough for Mule breeding.

PARROT SELF-PLUCKING (*E. C. O.*).—Give it no bones, meat, or stimulants of any kind, such as capsicums. Feed on bread and milk and fruit only. Let it bathe daily in a dishful of water, but if it declines bathing give it a shower bath daily by pouring over it tepid water through the rose of a watering-pot.

CANARY OR MULE (*Rev. S. A. B.*).—The hen which fights her mate, whether a Mule or a Canary, is of no use for breeding purposes, and the sooner a separation takes place the better, or the continual fighting may terminate in death. A want of thorough practical knowledge is the reason why you cannot "tell a hen Mule from a hen Canary." Mule hens will go to nest, and exercise their architectural skill in the like way as Canaries, and will deposit eggs in their nests the same size as Canary eggs; but they will be found to be unfertile at the end of the thirteen days' sitting. All Goldfinch hen Mules have a flush of colour on their faces, around their beaks, of a brooze-like tint, which point alone is sufficient to decide the matter whether the hen is a Mule. It is not an uncommon occurrence for the uninitiated to suppose a marked or variegated bird to be a Mule.

REMARKS.

21st.—Very misty morning, dull after; rain commenced at 7 P.M.; middle of the day warm; but much cooler in the evening.

22nd.—Rain at times all day, cold and dull. Extraordinary fall of temperature since yesterday.

23rd.—A fine day, though rather dull at times, and cold.

24th.—Fine all day, but still cold.

25th.—Fine early, and till 10 A.M., then gradually getting more and more thick and dark, till at 10.30 A.M. it was so dark as almost to require artificial light in the house; this lasted only for a short time, but it was thick and dark all the morning; but from 1.30 P.M. it was fine, and the night starlit.

26th.—Rather hazy early, but soon cleared off, and fine all the remainder of the day.

27th.—Again hazy early, but soon bright and fine.

A fine week; the decrease of temperature on the evening of the 21st being the most remarkable feature.—G. J. SYMONS.

COVENT GARDEN MARKET.—APRIL 28.

WE have experienced a slight improvement in the amount of business transactions; orders from the northern and midland counties being more extensive. The supply of French Asparagus is now becoming large, especially from the south, and advices report a continuance of it. Salading of the usual description is excellent. Heavy consignments of Broccoli are to hand this week, with some abatement in the price among the wholesale dealers.

From observations taken near London during forty-three years, the average day temperature of the week is 64.6°; and its night temperature 41.1°.

HARDY EARLY SPRING FLOWERS.

OF late years one of the most popular pursuits in gardening has been the cultivation of spring flowers, and to such an extent has this been followed by some, that as much trouble is taken and as much interest is centered in the "spring bedding" as in that which follows in the summer. I find no fault with its being so, and where the means are forthcoming both may be accomplished pretty well. Furthermore, there is something especially cheering in the presence of spring flowers, and the earlier they can be had the better; and if those who cater for us could increase the number of really early-flowering plants of a pleasing colour and easy culture they would accomplish an object of more value than by issuing new varieties of Golden and other bedding Geraniums. Really early-flowering plants are but few, and the spring gardening, as it is often miscalled, is allowed to straggle on into the early summer, many of the plants now used for the purpose not flowering until May. In the country spring flowers may be met with in every coppice or hedgerow—the wild Hyacinth, Gorse, May, Cuckoo-flower, and many others, which all tend to lessen the value of the parterre at that time, however gay it may be with Pansies, Forget-me-nots, Silenes, Violas, and the many interesting annuals that flower at this season; so that it is more important for cultivators in rural districts to patronise the earlier class of flowering plants, leaving it to the caterer for town or suburban flower beds to cultivate the later-blooming kinds, as he will have less immediate competition from Dame Nature, and will have the field more to himself.

Of course the requirements of certain places point out what has to be done, but I have often thought that spring gardening as it is frequently met with is not so important as it is often thought to be when trees and shrubs of so many kinds are all in their best garb, and Nature's flowers competing for floral honours at the same time as the beds of the parterre which they surround. But I fear it is something like sedition to speak against spring gardening in any form; I will therefore urge on all to try and encourage the cultivation of earlier-flowering plants, and see if by cultivation flowers cannot be coaxed to precede those which are growing wild. Here I admit our materials are as yet limited, but I hope to see them augmented by plants not yet thought of. I should like to see something like a system or plan of providing flowers from January down to the time the cuckoo makes its appearance. Of such early flowers my list is a meagre one, and is no doubt capable of being supplemented by many readers.

I have never been able to make much of the Christmas Rose (Helleborus niger), which with me seems to flower best when nestling underneath some tree or shrub, and has not been disturbed for some years. Winter Aconite (Eranthis hyemalis) is more convenient, and bears removal much better; but that I have also grown mostly as edgings to Rose and other beds, where it enjoys a permanent position; still it is available for the temporary purpose of ornamenting the beds, for even after it has done flowering its foliage presents an agreeable appearance, which is not the case with all plants.

We next come to the Snowdrop; and I am much surprised this plant is not more patronised both in public and private gardens than it is, for it is certainly one of the most convenient of all early spring flowers, and bears transplanting at any period of its growth. With us it is mostly planted when it is in a growing state, tufts of it being taken up soon after it makes its appearance above ground, as well as when it is in full flower or afterwards; but where it is intended to do duty the same season I would recommend its being planted in tufts that may be about an inch or so high, when it will flower and do well at once. Having so many masses of shrubs edged with it, very often on the turf, as well as walks through shrubberies or under trees where nothing else will grow, we do not use it much for beds; still it may be available for that purpose. I may add here for the information of those who have not tried the Snowdrop under trees, that it is an excellent plant to form embroidered figures and any kind of fancy work, which looks very pretty on places where the herbage is confined to Pilewort and a few other weeds of a like kind, which scarcely present any signs of life when the Snowdrop makes its appearance. If planted thinly it does not require altering for some years. Where walks lead through shrubberies or under trees where only a few bulbs make their appearance, and where the edging of the walk is defined by a stone or brick kerbing, the Snowdrop may be planted in a line about a foot from the side of the walk, and answers admirably; neither is it unsightly after flowering, for the foliage curving gracefully over to both sides looks both fresh and orderly. When grown on grass it is better not to mow until it shows tokens of decay setting in, which is usually about the middle of May or earlier.

I have never been able to make much of the Crocus, which with me has always fallen a victim to mice or other enemies, that excepting in some detached patches (and these every now and then being destroyed), I have done very little in outdoor decoration with them. I regret this much, for the many colours we have of this bulb would make it very acceptable. I may add that rabbits are fond of the foliage when it is in a growing condition, although they do not meddle with the Snowdrop nor common Daffodil further than mischievously scratching them up occasionally.

We now come to the important Primula family, amongst which are some of the most serviceable of all our spring-flowering plants. Notably so is the single white Primrose and the single mauve, both being early, the first-named often flowering profusely in the autumn and up to Christmas if the weather be mild. The two varieties above mentioned may be classed amongst the early-flowering plants of the year. Next follows the wild or common Primrose, after which the single crimson, violets, and other intermediate colours, most of which, especially the

crimsons, have a tendency to run into the Polyanthus form. Amongst several hundred plants I have of a rather pretty and bright crimson all have the tendency to sport in the manner described; they are earlier than the ordinary Polyanthus, and also earlier than the double-flowering Primrose, and on the whole flower more abundantly. The double varieties when well grown flower freely also; but my collection of these is limited to the white, yellow, and lilac. The greatest favourite here is the Hose-in-hose Oxlip, which I fancy is not generally known, and which when well grown is more densely covered with bloom than any variety I know of, and that, too, of a bright clear yellow, not the pale hue of the ordinary Primrose. Unfortunately it does not seem to perfect any seed with me, neither does a pretty lavender-coloured Polyanthus which forms a strong contrast to it, and is equally admired for its free-blooming qualities as for its colour. But I fear I must exclude the whole of the Polyanthus family from the section of very early-flowering plants, for April is usually far advanced before they are at their best. The single white Primrose, however, is usually the earliest of all winter-flowering plants, and being of a neat and compact habit, is available for most places where the Primrose is required.

Erica carnea and herbacea are useful and highly ornamental plants. I confess not to have used them much for winter-decorative purposes in the way of filling empty beds, for the reason that we have plants growing elsewhere in a permanent manner, so that it is not wanted for the temporary purpose of replacing the Geranium and other summer-flowering plants. I have no doubt it can be used to advantage, and more especially with those who have a congenial soil for it to grow in. The plant is so very accommodating that it thrives in most places, and is amongst the earliest flowers we have. It is very hardy and second to none for compactness of habit and profusion of flowers, and as these stand all weathers it may be set down as one of the most useful and becoming of all early flowers.

Daffodils and other Narcissi are beautiful and interesting plants, but I have my misgivings about recommending them for beds, and would rather advise their being planted in some less conspicuous place, as in the fronts of shrubberies or underneath trees near to walks. They are also suitable for the mixed herbaceous border, and even now and then amongst grass in places where the scythe is not likely to cut them down before their foliage begins to decay. All such places where not too dry answer very well for the common Daffodil, its presence in such places is more becoming than in the parterre.

Forget-me-not and Arabis albida. For many years I have grown these two plants rather extensively, as being a very good match in habit and widely diverse in colour. Usually the first flowers on each are not more than two or three days apart. The Forget-me-not, which with me is the dissitiflora species, is the most attractive when examined closely. When in the pink condition, which is the garb it first of all puts on (and this season was very late indeed in shaking off), it is certainly not so good as the Arabis. But it is idle making a comparison since both are wanted, and being widely dissimilar colours they cannot compete with each other. I am, however, uncertain whether to class them in the list of very early flowering plants, as they are very rarely at their best until April, and in some seasons like the present not until the latter end of it. Their utility as representing masses of blue and white in the most compact form cannot be too highly commended.

Pansies and other Violas. I confess not to have employed the Viola to the extent I find others have done. With me it only blooms in the early summer months. I allude to V. cornuta and its varieties. Pansies are apt to go off entirely during the dry summers we are frequently visited with. One or two popular varieties, notably the Cliveden Blue, is extremely pretty later in the spring and deserves the highest praise, as also does a yellow one having only a local name, and not conforming to the conditions laid down for a florist's flower. The whole family are, however, useful, or at least the kinds usually met with in cultivation are all admired; and for furnishing beds near to walks much frequented they may be planted with advantage.

Hepatica is on the whole a more serviceable plant when occupying a permanent position in the herbaceous border, as I have never met with it in a good condition where it had to endure transplanting twice in a year. With me it does not thrive very well. The single blue is my favourite.

Daisies are much too late to be classed in the list of very early flowers, and I fear the assumed improvement made in them has not been in the direction of earliness. They are, however, extremely pretty in May. The clear white and dark red being in my opinion more showy than the intermediate colours.

Saxifragas. These plants are more remarkable for foliage than for flowering; but S. crassifolia looks well in winter, besides having a fine spike of rose-coloured bloom in the early part of April. The most of the other species are more showy in their foliage than in their flowering, and may be treated of hereafter.

Helleborus fœtidus. Like the last, this plant unites the twofold recommendation of being good in appearance as a foliaged plant, and by its flower being interesting. When in flower it is 18 inches high or more, but being clothed with Palm-like foliage of a dark-green colour to the ground its appearance is handsome at all times. In hardihood it is second to none, standing as it does equally well in the open bed or elevated vase. For winter and early spring gardening I have for many years placed this plant first, and have not seen reason to alter my decision.

Amongst other early-flowering plants much to be admired is Alyssum saxatile, especially a dwarf variety of it of a bright golden yellow, and enduring the sun much better than Cheiranthus Marshallii, besides being earlier, still not early enough for this list. Neither are the Wallflowers nor any of the various annuals, which are exceedingly useful in their way, but comparatively few flower before May. Bright clear-coloured flowers on tidy-looking plants which flower before April seem desirable, and experience of such plants would be valuable.

I should say that everything recommended for early decoration should precede the Polyanthus. This being a widely known plant may be placed as denoting the demarcation between the early and late spring-flowering plants. For late spring we have no lack of choice, but any addition to really early flowers will be very acceptable.—John Robson.

AIDS TO FERTILISATION.

The winter, which we may now hope is almost gone, has been a very trying one for the forcing gardener, not on account of the severity of the weather, for with one notable exception (31st December), when the ground was beautifully and effectually covered with Nature's blanket, we have had no severe frost, but because of the absence of sunshine. Caloric we can manufacture, daylight we cannot, and without the latter the former is comparatively useless for plant life. You may have elongation without sunlight, but it can scarcely be called growth, and when at last sunlight does come, the plants will suffer as much from it as they had previously done from its absence.

Probably one of the greatest difficulties this season has been with the fertilisation of flowers, such as Peaches, Strawberries, and Vines. Before this is forgotten I should like to invite those who have had difficulties, and partial failures, to think over the matter a little, with a view to being better prepared to meet such difficulties in future.

The following remarks are merely intended to be suggestive, as I have not time now to go deeply into the matter if so inclined, and, besides, I would rather encourage our rising young gardeners to think for themselves than lay down laws and rules for them to follow without reason. Exceptional seasons like this go far to prove who are the thinking and reasoning gardeners, and to divide them from those who blindly and mechanically copy their forefathers. Copying a good master is all very well when the conditions and requirements are the same; but a little variation in the conditions or requirements will often upset the whole affair, and the copying pupil is lost in a maze.

What are the conditions generally favourable to the fertilisation of flowers? And when the conditions are unfavourable how can we best assist Nature to perform her functions? First of all we must have mature growth. You might as well try to keep-up a supply of Mustard and Cress without seed as to force Grapes, Peaches, and Strawberries where the buds and crowns were not matured the previous season. Have good, plump, ripe growth, and you can afford to smile at those who tell you that the plants require rest. As a rule plants rest only to accommodate themselves to the seasons. The growth once matured the plant is immediately able and willing to start afresh if introduced to a suitable climate natural or artificial.

Healthy, but not rampant, root and leaf action are an ab-

solute necessity to fertilisation. A genial atmosphere should be maintained—certainly not a dry and hot one, as is so often recommended in our gardening periodicals, but one containing sufficient warmth to prevent anything like stagnancy, and enough moisture to prevent flagging. Cold draughts should not be admitted. When there is no sunshine, a very little warmth in the pipes and the smallest aperture at the apex of the roof will give quite sufficient buoyancy to the air of the house. In the case of Vines and Peaches a gentle shake of the trellis will help to distribute the pollen.

I do not think it at all necessary to touch the flowers with the hand or any implement, and I firmly believe that there is more harm than good done by it. The little caps which cover and protect the blooms of Vines always fall off mine at the proper time, and why should they not do so with other growers? The little globules on the stigma, so much talked of and written about, do not prevent impregnation here, and I cannot quite understand why they should do so elsewhere.

Peaches will generally set well enough if the flowers are perfect and the atmosphere suitable. If the flowers are not perfect something besides is probably wrong; and if by any scheming you can make them set artificially, it is not at all likely you will force them to ripen good fruit.

This season for the first time I have found ants damaging flowers and fruit. I always thought before that they did no more than dance attendance on the green fly. Now as I have no green fly for them they have revenge by sucking the juices of the flowers. I have had Peach and also Melon flowers entirely destroyed by them, and now they are trying the flavour of the ripe Strawberries. I have read that toads will destroy ants. We have plenty of toads, but they do not care at all for such small fry, they prefer worms and wasps. A dozen wasps is nothing unreasonable for a hungry toad, and I must therefore think it would take him a long time to make a meal off ants. But to the flowers.

I ventured to hint in a former paper that the impregnation of the Strawberry was a sort of compound affair, that to have a perfect fruit it is necessary for all the little hair-like organs in the centre of the flower to be impregnated, and where these are not impregnated the seeds will not be formed, and the fruit will not swell in that particular part. This is the cause of badly-shaped fruit. Each seed affects the swelling of the fruit about an eighth of an inch all round it; if there is a space of more than a quarter of inch, when the fruit is fully grown without a perfect seed there will be a malformation. These observations are taken from Keens' Seedling. Some varieties may have the seeds closer and some further apart. I have lately had more proof of the above than I wished for. During the sunless weather of March, when we could not keep sufficient warmth in the pipes in the Strawberry house to make the air buoyant without raising the temperature too high, I took the precaution to fan the flowers once every day for a time when they were fully expanded. It was done with my hat as being the most convenient, and I am sorry to say I spoilt the shape of it. I gave it a sharp whisk before the flowers so as to cause them to move without touching them. The effect was plainly visible in the shape and appearance of the fruit. As the season was advancing and the days growing longer, I left the next succession batch to take care of themselves, and a lot of miserable, ugly, deformed fruit was produced, such as I was glad to see the last of. I now put my man in charge up to the fanning dodge, and the fruit again was all that could be wished for. In ordinary seasons a knowledge of this practice is of no consequence, but in a sunless season, like the present one has been till lately, I think it of the greatest importance.

It is interesting to observe how beautifully Nature provides for the fertilisation of the Strawberry flower. The outer stamens are longer than the inner stamens, and soon after the petals expand these longer stamens may be seen bending over so as to cover the tip of the future fruit. They remain there till the little vessels burst and distribute the pollen, and then almost immediately they recede and begin to decay.—William Taylor.

Philadelphia International Exhibition of 1876.—The applications for space in the British section of this Exhibition are numerous and of a satisfactory character. In consequence, however, of arrangements recently communicated by the American authorities, whereby the time for foreign commissions to make definite application for amount of space required is extended, it will be possible for the British Executive to receive applications from intending exhibitors, addressed to 5, Craig's Court, Charing Cross, London, up to the 15th of May inclusive.

ALPINE AURICULAS.

This alpine beauty, so developed by the labour which has been bestowed on it, more especially in years gone by, has indeed acquired an extravagant diversity of minutely exquisite tints—considering the limited variations it was originally known to possess in its wild state—blending in what are termed variegated flowers in a really marvellous manner, and forming a pleasing contrast to those of one colour known as selfs, the plant varying also in a yellow or white eye. As if its beautiful shades of colour alone did not demand for it universal attention, it also yields a delicious Primula-like scent.

My object in penning these few lines in favour of the alpine Auriculas is not so much to explain how they should be grown, for this has often been done by many able and experienced writers. I would rather speak of the adverse circumstances under which they (the flowers) may be cultivated, and the rough treatment they will survive, their independent character thus bringing them under the class of hardy perennial bedding plants. And yet how seldom are seen in private gardens more than one or two different varieties of the Auricula. As far as my experience goes they are of much easier culture than is generally supposed. It has been said that damp and full sunshine are their ruin.

My interest in this flower was first awakened by the surprise I felt at seeing it grown under great disadvantages, its beauty changing a very unattractive spot into one of marvel. This was a tiny walled-in garden or court facing the south—a receptacle, as may be supposed, for every kind of domestic odds and ends, being tenanted by an old mechanic in the narrow street of an uninviting part of a country town. I was assured this plot had no artificial assistance from manure, nor protection from sun nor wet. It was a light soil of poor character yet nurtured the Auriculas, which were produced there in nearly every shade of their colour. One of the most striking points was the nearness in which the plants were grown—literally touching each other on all sides. At length I had the good fortune of obtaining a collection of these April-blooming treasures, but at a period which necessitated a double move for them; each time they were stripped of all earth attached to their roots. The end of May was the date of their first transition, and September was the second. The latter time they were fully three days out of the ground, being then planted where they now stand, in a poor, sandy, stony soil, unsheltered from the elements, it being a high, exposed, and dry situation.

With all this their principal enemy is the cockchafer grub, which eats the roots here by wholesale in May, through which I lost a quantity of plants in the summer of 1874. With the exception of a tolerable amount of decayed farmyard manure in the autumn, and a dressing of soot in the early spring, with one later addition of a little liquid manure, they have had to look out for themselves, and where there is a plant that was left unmolested by the cockchafer grub it looks robust. Those that are smaller though now healthy have all suffered from its ravages. These pests eat the roots bare to the surface of the earth, for which I know no prevention. Some of the plants now blooming I had for two years previously on a dry bank facing the south, but shaded. The soil was stiff loam, in which they bloomed fairly, but made little growth, though still alive to tell the tale. In truth the tale they all tell is one of which I can never tire, for there seems daily a new attraction in their contemplation, in comparing their beautiful shades of purple, lilac, crimson, pink, maroon, yellow, and white. I have sent you a few pips of about fifty different flowers, which will show that with all their adverse circumstances they still have something to boast of.

I mention all these facts merely to demonstrate that Auriculas can be grown in many places where now, I believe, it is considered out of the question. If I had such a spot at my disposal I would select a rather shaded, moist, but well-drained bed for them, which is exactly the reverse of their present position in my garden. This is only one of the many beautiful hardy flowering plants that surely will again before long take a more prominent place in our gardens.—Henry W. Cooper, *Surrey*.

[The flowers which Mr. Cooper sent us were very varied in colour, large in size, and of good form. Our experience of these border Auriculas confirms what Mr. Cooper says, for they are among the most gay and hardy of our spring flowers;

and the improvement which has taken place in production of new varieties has of late been quite marvellous.—Eds. J. of H.]

EXHIBITION OF CLEMATIS AND ROSES AT THE ROYAL BOTANIC SOCIETY.

In the Society's gardens, Regent's Park, are now arranged what may be termed private exhibitions of the two finest hardy garden plants we possess—viz., the Rose and the Clematis. We will first glance at the

Clematises staged by G. Jackman & Son, Woking Nursery, Surrey, which are arranged in the conservatory corridor. Some idea may be formed of the collection when we state that it is composed of four rows of plants, each 60 yards in length, and numbers nearly four hundred specimens. Most of these are spherical masses of bloom 3 feet and more high and through, the front row being of smaller-sized plants, yet richly laden with flowers. The effect produced is exceedingly imposing and gay, yet is destitute of any approach to mere glare by the preponderance of neutral tints which pervades the collection.

We note as a few of the best:—Sir Garnet Wolsley, a splendid plant, a rich glow of crimson pervading the flowers by the broad centre band of that colour on a mauve ground. The Queen, a broad-sepalled variety of great merit, lilac, with claret stripe. Stella, an imposing light variety, with large blush flowers and sweet-scented. Ada, glossy mauve with a rosy band, very chaste. Lord Mayo, similar to Stella, but more lively, an effective variety. Patens floribunda, a tinted flesh-colour, suffused with lilac deepening to the centre; a fine but rather loose flower. Miss Crawshaw, a large flower of rosy hue with a beautiful satiny gloss on the sepals. Lord Derby, deep lavender shading to mauve, attractive. W. E. Everington, rich maroon with crimson band, an early dark variety, distinct as a cross between the early and late blooming class. Fair Rosamond, blush white, with a fainted red bar and distinct stamens; a fragrant variety. Aurelliana, deep lilac, a small but attractive variety; very free. Mrs. C. S. Baker, French white and claret. Vesta, a light sweetly-scented variety. Miss Bateman, still one of the best of the whites, and good examples of the excellent varieties Albert Victor, Lady Londesborough, Angelina, Rubella, &c. The above represent the cream of the splendid collection of single flowers. Countess of Lovelace is the best double variety, being a better colour, with larger flowers, and is altogether superior to John Gould Veitch. Lucie Lemoine, the double blush variety, is a fine companion plant to the foregoing. We cannot too strongly recommend the extended cultivation of this class of plants both for conservatory and garden decoration, and we especially advise all who can do so to see this admirable and complete collection for themselves. It continues until the 25th inst. Passing through the grounds we find the

Roses of Mr. Wm. Paul of the renowned Waltham Cross Nurseries arranged under canvas, in what was once the American or Rhododendron garden. The enclosure is about 50 yards square, and the space is laid-out in curving walks, surrounding raised beds and banks edged with grass verges. On these elevations are arranged about three thousand plants, principally Roses, yet interspersed with choice shrubs, specimen Ivies, Maples, Yuccas, &c.

Unlike the Clematis exhibition, which is a veritable bank of flowers, this collection of Roses, and auxiliaries, are arranged with the utmost natural freedom, and affords a stroll of much interest and beauty, and an atmosphere redolent with delicious perfume. It does not remind one of a mere set show so much as of a beautiful garden of Roses where each plant can be examined separately and apart from its neighbour. These plants are in all shapes and sizes. There are standards and dwarfs, huge pyramids 7 feet high, and globular masses of bloom of compact size and symmetrical form.

Amongst the giants are Souvenir d'un Ami, 7 feet by 6; Charles Lawson, 6 feet by 4; Madame Willermoz, 6 feet by 5; Céline Forestier, 6 feet by 5; Glory of Waltham, 5 feet by 4; with lesser, still fine rounded examples of Alba Rosea, Victor Verdier, Comtesse d'Oxford, fine; Duke of Edinburgh, Marie Van Houtte, Mdlle. Thérèse Levet, very fine blooms; Madame Lacharme, extra; Princess Beatrice, a fine globular Rose, and sweet; Marquise de Castellane, exceedingly good; La France, very fine. All these are heavily laden with blooms.

Smaller plants of the following are prominent by their excellence:—Madame Nachury, fine bold flowers; Peach Blossom, a sweet and excellent garden Rose; Catherine Mermet; Perfection de Montplaisir, a bright canary yellow; and Star of Waltham, exhibiting fine vigour of constitution, massive foliage, and rich blooms.

Altogether the collection of Roses is a very excellent one, some plants being remarkable for a large number of medium-sized flowers, some for a few blooms of splendid finish, some for richness of colour, others for delicacy of tint, and all for the cleanliness and health for which Mr. William Paul's plants are proverbial.

Besides the Roses are attractive groups of Pelargoniums, a bed of silver-edged varieties with white flowers being especially noticeable. The best of these is, perhaps, Mont Blanc, closely followed, however, by Imogene, Mountain Maid, Virgin Queen, and Waltham Bride. This group has an exceedingly chaste effect. The best of the silver tricolors are Miss Farren, free and good; Madame Patti, compact; Lady Dorothy Nevill, bright; and Princess Beatrice. Plutarch is one of the best gold tricolors, being bright and of good substance; and Midas, a gold bicolor, is a smooth, clearly-defined, high-coloured variety. Altogether the Exhibition is worthy of the effort and enterprise of the promoter, and more need not be said. It continues until the 10th inst.

NATIONAL AURICULA SOCIETY'S SHOW.

The above was held on April 27th, and was so arranged for as to form one feature, and that a distinctive one, of the Manchester Botanical Council's Exhibition in the Town Hall, King Street.

It is much to be regretted that the supply of daylight, which has never a very high illuminating power in Manchester, should be so insufficient for a flower show here. At farthest from the windows it seems mere twilight; and though bright Orchids may shine through such a gloom, and Roses, Azaleas, and Rhododendrons, by sheer force of floral power, make their presence felt, yet smaller flowers with such tender touches and curious shades of colour as characterise the florist Auricula suffer much in a defective light. I have stated this in great measure for the sake of defending the Auricula from a possible charge that it does not come out so well as might be expected at an exhibition. In want of a fair light it cannot; but lovely as it is under all exhibition advantages, it is never so pretty as at home in a cool dustless air and carefully adjusted light.

The Show of the 27th was as good as any of us had expected it could be after the tedious spring. The whole growing season has been very difficult for Auriculas, and they have required care during the long continuance of dry cold winds at the time when the stems were rising and the buds swelling. Hardy as the Auricula plant itself is, the blossoms are most tender, and the shortest chill upon the opening flowers will stop them in their progress and cause them to "set"—*i.e.*, remain fixed in the position they were in when subjected to the check. My late notes upon Auriculas will, I trust, render it unnecessary that I should in the Journal repeat them.

I was too busy to thoroughly enjoy the Show, but two fresh varieties in selfs were noticeable. One of them, raised by Mr. E. Pohlman of Halifax, and now named Ellen Lancaster, is a very intensely dark flower of fine outline and rich flat petal, paste not quite circular, and might with advantage be broader and denser; but in a kinder season the flower may improve in this last quality, and, indeed, has been seen in better condition, and very fine. The other self is Charles Perry, one of the blues, the best of them all in breadth, roundness, and flatness of petal and in richness of colour, which is a very desirable one. Like them all, however, the tube is very pale; it seems a weak point in all the flowers of this colour, so that the first good blue we can raise with a golden tube will be a great catch. Charles Perry has come out through Mr. Charles Turner, but the dark self is not yet let out, though it has passed from the raiser's hands.

One point of interest connected with the Show which I would notice with most pleasant recollection was the meeting of florists after the Show. We always draw together at some appointed place after such exhibitions as the National Auricula, Tulip, or Carnation and Picotee Society, and our smaller shows have also their more local gathering. But this time we were richer than usual in the presence of florist friends from very far, and very greatly it added to the good cheer of the day to meet those hand-to-hand with whom one had but corresponded hitherto. A little knot among us who had been thus related had a hearty laugh together as we confessed among ourselves that we had found we were all younger and heartier men than we had supposed one another to be. I trust that many a like re-union awaits us. They are happy meetings, and one of the many pleasures we derive from the simple source of flowers, and they are by no means the least pleasurable part of an exhibition.

I am sure I speak for all my brother "Northerns" when I say we feel the sympathy and help of brother florists in the south and over the water as far as Ireland, and I trust that all

the friends who met us the other day, some for the first time, will think one line from Tennyson may describe us well—

"Dark, and true, and tender is the north."

AURICULAS.

Class A. Six dissimilar.—1st, Rev. F. D. Horner, Kirkby Malzeard, Ripon, with Prince of Greens, Smiling Beauty, George Lightbody, Complete, Regular, Pizarro. 2nd, Charles Turner, Royal Nurseries, Slough, with R. Trail, Alderman Wisbey, Colonel Champneys, George Lightbody, Cygnet, Charles Perry. 3rd, H. Wilson, Halifax, with Colonel Taylor, Imperator, Favourite, George Lightbody, Pizarro, Othello. 4th, S. Cooper, Timperley, with Imperator. Lovely Ann, Ann Smith, John Wateston, Mrs. Sturrock, Parker's Metropolitan.

Class B. Four dissimilar.—1st, C. Royds, Rochdale, with Imperator, Smiling Beauty, Conqueror of Europe, Mrs. Lancaster. 2nd, Rev. F. D. Horner, with Smiling Beauty, George Lightbody, Bolivar, Mrs. Sturrock. 3rd, S. Cooper, with Imperator, Taylor's Glory, Conqueror, Pizarro. 4th, Charles Turner, Alderman Wisbey, Privateer, Arabella, Blackbird.

Class C. Dissimilar Pairs.—1st, C. Royds, with Imperator, Mrs. Lancaster 2nd, Rev. F. D. Horner, with Prince of Wales, George Lerrick. 3rd, E. Elliott, Rochdale, with George Lightbody, Pizarro. 4th, R. Lord, Todmorden, with Colonel Taylor, Pizarro.

Green edges, single plants.—Premium, R. Lord, with Colonel Taylor; 1st, Rev. F. D. Horner, with Colonel Taylor; 2nd, R. Lord, with Imperator; 3rd, Rev. F. D. Horner, with Lady Wilbraham; 4th, Rev. F. D. Horner, with Apollo (Beeston's); 5th, C. Royds, with Lovely Ann; 6th, R. Lord, with Trail's Anna; 7th, Charles Turner, with Hertfordshire Hero; 8th, C. Royds, with Prince of Wales.

Grey edges, single plants.—Premium, Rev. F. D. Horner, with Kay's Meiklejohn; 1st, Rev. F. D. Horner, with George Lightbody; 2nd, Rev. F. D. Horner, with Complete; 3rd, R. Lord, with Charles Brown; 4th, S. Cooper, with R. Trail; 5th, Rev. F. D. Horner, with Kay's Meiklejohn; 6th, J. Rowland, Prestwich, with Alma; 7th, — Mellor, Ashton, with Conqueror; 8th, Rev. F. D. Horner, with Ne Plus Ultra.

White edges, single plants.—Premium, Rev. F. D. Horner, with Catharina; 1st, E. Elliott, with Catharina; 2nd, C. Turner, with Omega; 3rd, H. Wilson, with Smiling Beauty; 4th, C. Turner, with R. Headley; 5th, R. Lord, with Bright Venus; 6th, R. Lord, with True Briton; 7th, E. Elliott, with R. Trail; 8th, Rev. F. D. Horner, with Taylor's Glory.

Selfs, single plants.—Premium, Rev. F. D. Horner, with Othello; 1st, R. Lord, with Pizarro; 2nd, C. Turner, with C. Perry; 3rd, R. Gorton, Eccles, with Topsy; 4th, Rev. F. D. Horner, with Lord Lorne; 5th, H. Wilson, with Garibaldi; 6th, H. Wilson, with True Blue; 7th, J. Rowland, with Lord Clyde; 8th, R. Lord, with Meteor Flag.

Best Green edge in the Exhibition.—R. Lord, with Colonel Taylor.

Best Grey edge in the Exhibition.—Rev. F. D. Horner, with Kay's Meiklejohn.

POLYANTHUS.

Pairs dissimilar.—1st, J. Rowland, with Lord Lincoln and Exile; 2nd, T. Mellor, with Cheshire Favourite and Exile.

Single Plants.—Premium, J. Rowland, with Cheshire Favourite; 1st, D. Jackson, Middleton, with Lincoln Seedling; 2nd, — Mellor, with George IV.; 3rd, Rev. F. D. Horner, with a seedling; 4th, J. Rowland, with Exile; 5th, J. Walker, Sheffield, with a seedling; 6th, — Jackson; 7th, R. Lord, with Cheshire Favourite; 8th, T. Mellor, with Exile.

ALPINE AURICULAS.

Yellow Centres.—Premium, C. Turner, with Bessie Ray; 1st, S. Cooper, with Nimrod; 2nd, S. Cooper with Ovid; 3rd, R Gorton, with Alice; 4th, R. Gorton, with Diamond; 5th, R. Gorton, with Dolly Varden; 6th, C. Turner, with Bronze Queen; 7th, R. Gorton, with John Leech; 8th, C. Turner, with Evening Star.

White Centres.—Premium, R. Gorton, with Mauve Queen; 1st, S. Cooper, with George Lightbody; 2nd, R. Gorton, with Miss Reed; 3rd, R. Gorton, with Beatrice 4th, C. Turner, with Castalia; 5th, R. Gorton, with Purple Emperor; 6th, R. Gorton, with Consolation; 7th, J. Wild, Middleton; 8th, R. Gorton, with George Lightbody.

—F. D. Horner, *Kirkby Malzeard, Ripon.*

FORTUNE'S YELLOW ROSE.

We have received from Mr. J. Muir Dowie a "few buds"—really attractive button-hole flowers—of Fortune's yellow Rose. This Rose was introduced from China by Mr. Fortune in 1845. It was not issued with a flourish of trumpets, but, on the contrary, it was somewhat disparaged as a shy-blooming Tea Rose of weak constitution. That it is not shy-blooming is evident, and as to its delicacy it has lived thirty years without exceptional nursing. In reality it is a good, free, and attractive Rose; but to see it to advantage it should be grown on the roof of a greenhouse or conservatory, where its pendent blooms are conspicuously beautiful. The colour is a rich coppery buff; buds elongated; foliage very bright, abundant, and almost evergreen. As a roof-covering plant it is very recommendable, and is in a fair degree hardy as a wall Rose in the open air. We are glad Mr. Dowie has directed attention to this too-much-neglected Rose, which he evidently grows so well.

AURICULAS AT THE ROYAL BOTANIC SOCIETY.

As Secretary of the Metropolitan Floral Society it is my duty to say a few words as to our little exhibition of these lovely spring flowers, and I only wish that I could speak more encouragingly of the increase of interest in them than I am enabled to do. Why is it that in the south we cannot induce persons to grow them? Mr. Ball, Mr. Charles Turner's able and intelligent foreman, who has grown his Auriculas for so many years, had been the day before at Manchester, and there had seen such an array of plants that it quite dazed him, exhibitors coming forward by scores, and hundreds of plants staged; and yet in all the south there are but four of us who can come forward, and one of these, Mr. Douglas, who has now taken a foremost place, had never been a grower had it not been for the encouragement given to the flower by our Society. However, let us take courage. We may by persistence induce others to grow them, especially if we can disabuse their minds of their being a difficulty in growing them.

The present season has been a disappointing one to some of us here in the south. My plants were not in bloom: probably I might have had them in by giving them greenhouse treatment, but the date was late, and I thought surely they would have been in. But of all my Richard Headlys I had but one in flower, no George Lightbodys, Smiling Beauty, Glorys, Lancashire Heroes, so that I could show but indifferently. Mr. Turner and Mr. James complained of the same, and Mr. Douglas had his forward by putting them into his greenhouse. His plants were wonderful for their vigour and size of truss, but in my judgment they lacked a good deal of that refinement which is one of the charms of the Auricula, and a thorough Auricula fancier would have said in most of them that there was too much body colour. Owing to the lateness of the season there was not the chance of seeing so many varieties as might otherwise have been the case, but the following were noticeable:—Alderman Wisbey in Mr. Turner's collection was a very fine green edge, as was also Admiral Napier in Mr. Douglas's, of which he had a plant in splendid condition. Amongst grey edges Col. Champneys, which was in each collection, was remarkable for the brilliancy of its colour and also for its remarkably fine habit. Alderman Charles Brown was very good, while a plant of Chapman's Maria in Mr. Douglas's group was remarkable for the grandeur of its truss and the unique brilliancy of its ground colour; and "though I says it as oughtn't to," the plant of Richard Headly with which I took first in class-showing was generally acknowledged to be a "real beauty." In white edges there was nothing very noticeable. Neither Taylor's Glory nor Hesp's Smiling Beauty, perhaps the two best white edges we have, were shown. Smith's Ne Plus Ultra was good. In selfs Lightbody's Lord Clyde, Campbell's Pizarro, and Martin's Mrs. Sturrock were well shown. Charles J. Perry is a very beautiful blue flower, but it is rather thin in substance but good in habit. Master Hole was also a very neat and well-formed flower. I hope that some other growers will come forward and restore the Auricula to the place it used to hold in and about the metropolis.

The prizes were awarded as follows:—Twelve Auriculas (open), first, Mr. Charles Turner; second, Mr. J. Douglas; third, Mr. J. James; extra, Rev. H. H. Dombrain. Six Auriculas (amateurs), first, Mr. J. Douglas; second, Mr. James; third, Rev. H. H. Dombrain. One green edge (open), first, Mr. Turner; second, Mr. Douglas. One grey edge (open), first, Rev. H. H. Dombrain; second, Mr. James; third, Mr. Douglas. One white edge (open), first, Mr. James; second, Mr. Turner; third, Mr. Douglas. One self (open), first, Mr. Turner; second, Mr. Douglas; third, Mr. James. Twelve Alpines (open), first, Mr. Turner; second, Mr. James; third, Mr. Douglas.—D., *Deal.*

NOVELTIES IN THE ROYAL GARDENS, KEW.

Dendrobium linguæforme is a curious and interesting species; and it matters little whether it is considered as an object of curiosity on account of its leaves or of beauty on account of the flowers, since in either case it is worth cultivation in the choicest collection. The flowers are pure white, with narrow sepals and petals. It was first found by Sir Joseph Banks in the Pacific Islands during the celebrated voyage of Captain Cook; subsequently it was collected at Port Jackson, and more recently has been sent to this country from Moreton Bay. It requires a cool house, and does best on a block.

Of no less beauty, but of different type, we may mention Angræcum, or, as it is sometimes called, Limodorum falcatum. It forms a small tuft of narrow and rigid dark green leaves intermingled with about a dozen pure white flowers, in general appearance the exact diminutives of A. sesquipedale. It does well on a block, and seems to be of free-flowering habit. It is a native of China and Japan.

Oncidium sarcodes is very showy with large finely marked flowers. It is somewhat rare, and is often done duty for by O. pubes. They are quite distinct in flower, and the latter is much the inferior. Among others in passing we may remark Odontoglossum gloriosum, O. luteo-purpureum, Cypripedium niveum, Oncidium bifolium, Dendrobium Farmeri, and Trichopilia suavis.

In the Cape house a very rare and remarkable plant is in flower. From the leaves at a first glance it would seem to be a Cyclamen, but underneath are flowers that indicate a totally different affinity. This is Heterotropa asaroides, belonging to the Aristolochia family, and closely allied to Asarum, with

which it should, perhaps, be united. The perianth is globose, about as large as a walnut and contracted to a wrinkled mouth, with a limb of three triangular segments. The colour is blackish purple. It is figured in the "Botanical Magazine" of 1840, and is a native of Japan. A flower appeared on this plant a short time ago, having one of the perianth segments developed in the form of a leaf-blade, assuming the leaf form, colour, and venation. It should have a shady corner in the greenhouse, and when at rest must not be kept quite dry.

NEW BOOK.

The Fruit Manual: containing the Descriptions, Synonymes, and Classification of the Fruits and Fruit Trees of Great Britain; with a hundred and one engravings of the best varieties. By Robert Hogg, L.L.D., F.L.S., Pomological Director of the Royal Horticultural Society, &c. London: *Journal of Horticulture* Office.

This volume, now in its fourth edition, is very much enlarged both in the size and number of its pages—they amount to six hundred. They contain the fullest and most accurate information for identifying and estimating our fruits. I shall give one extract that readers may judge of it themselves; but it would be false delicacy if I did not add that it is worthy of the author, who, the Burgomaster of Ghent, when he proposed his health at the public dinner of the great Antwerp Horticultural Show, entitled "the Linnæus of pomology."—G.

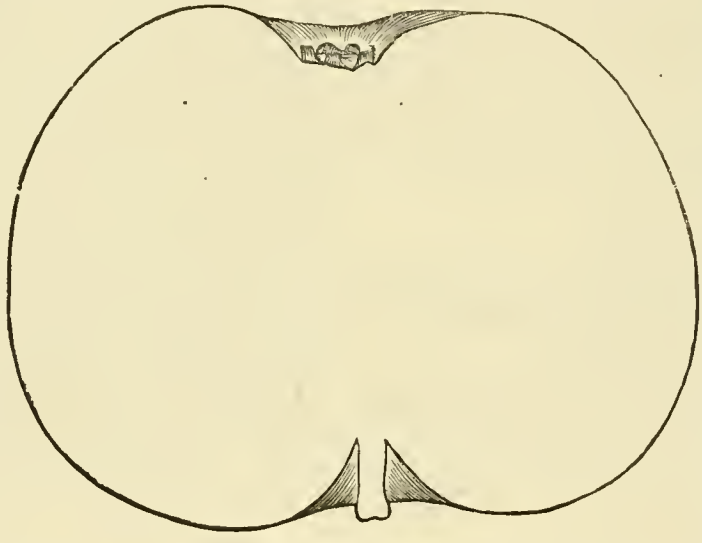

Fig. 83.—Blenheim Pippin.

"Blenheim Pippin (*BlenheimOrange; Woodstock Pippin; Northwick Pippin; Kempster's Pippin*).—Fruit, large, being generally 3 inches wide, and 2½ high; globular, and somewhat flattened, broader at the base than the apex, regularly and handsomely shaped. Skin, yellow, with a tinge of dull red next the sun, and streaked with deeper red. Eye, large and open, with short stunted segments, placed in a round and rather deep basin. Stalk, short and stout, rather deeply inserted and scarcely extending beyond the base. Flesh, yellow, crisp, juicy, sweet, and pleasantly acid.

"A very valuable and highly esteemed Apple, either for the dessert or culinary purposes, but, strictly speaking, more suitable for the latter. It is in use from November to February.

"The common complaint against the Blenheim Pippin is that the tree is a bad bearer. This is undoubtedly the case when it is young, being of a strong and vigorous habit of growth, and forming a large and very beautiful standard; but when it becomes a little aged it bears regular and abundant crops. It may be made to produce much earlier if grafted on the Paradise stock, and grown either as an open dwarf or an espalier.

"This valuable Apple was first discovered in Woodstock in Oxfordshire, and received its name from Blenheim, the seat of the Duke of Marlborough, which is in the immediate neighbourhood. It is not noticed in any of the nursery catalogues of the last century, nor was it cultivated in the London nurseries till about the year 1818.

"The following interesting account of this favourite variety appeared some years ago in the *Gardeners' Chronicle*:—'In a somewhat dilapidated corner of the decaying borough of ancient Woodstock, within 10 yards of the wall of Blenheim Park, stands all that remains of the original stump of that beautiful and justly celebrated Apple, the Blenheim Orange. It is now entirely dead, and rapidly falling to decay, being a mere shell about 10 feet high, loose in the ground, and having a large hole in the centre; till within the last three years it occasionally sent up long, thin, wiry twigs, but this last sign of vitality has ceased, and what remains will soon be the portion of the woodlouse and the worm. Old Grimmett the basket-maker, against the corner of whose garden wall the venerable relict is supported, has sat looking on it from his workshop window, and while he wove the pliant osier has meditated, for more than fifty successive summers, on the mutability of all sublunary substances, on juice, and core, and vegetable, as well as animal, and flesh, and blood. He can remember the time when, fifty years ago, he was a boy, and the tree a fine full-bearing stem, full of bud, and blossom, and fruit, and thousands thronged from all parts to gaze on its ruddy, ripening, orange burden; then gardeners came in the spring-tide to select the much-coveted scions, and to hear the tale of his horticultural child and sapling from the lips of the son of the white-haired Kempster. But nearly a century has elapsed since Kempster fell, like a ripened fruit, and was gathered to his fathers. He lived in a narrow cottage garden in Old Woodstock, a plain, practical labouring man; and in the midst of his bees and flowers around him, and in his 'glorious pride,' in the midst of his little garden he realised Virgil's dream of the old Corycian: 'Et regum equabat opes animis.'

"'The provincial name for this Apple is still 'Kempster's Pippin,' a lasting monumental tribute and inscription to him who first planted the kernel from whence it sprang.'"

VEITCH'S AUTUMN GIANT CAULIFLOWER.

Permit me to speak a word in favour of this well-known vegetable, not, however, because it is a large variety, for as a rule I consider large vegetables are not the most meritorious; neither for any superior flavour do I recommend it, for on this point I conceive it is no better than, if as good as the Walcheren. Its great advantage is its power of resisting the ill effects of drought. Being in a dry district it has been a hard fight to carry Cauliflowers through the summer for a full autumn supply, but with this variety I feel sure of a crop. Last summer when we were without rain for months, and the plantations of Cauliflowers were like dead sticks, this variety alone sustained the trial, and gave in the autumn a supply of great value, and which was in use throughout October and November, at least until destroyed by the severe frost. For prolonged autumn use the seed of the Autumn Giant should be sown at the present time, as it is much longer in attaining its growth than any other kind. By planting 18 inches apart in not over-rich soil small heads are produced which for table purposes are more serviceable than the "Giants." Unlike other varieties it does not button prematurely in a poor soil, and the ordinary autumn rains afford a sufficient stimulant to produce crisp sweet Cauliflowers 3 to 4 inches in diameter. A dish of three or four of these is at all times more satisfactory on a gentleman's table than is one head so large that it must be smashed or mutilated to squeeze it beneath the dish-cover. Sown now for autumn use it is a vegetable of great value, and should be grown in every district where drought is usually prevalent, as it will yield heads when all other varieties are burnt up.—A Kitchen Gardener.

ROSE GROWING.

In some perhaps trifling matters Mr. Taylor and myself do not quite agree, but the many practical articles that adorn the pages of the *Journal of Horticulture* from Mr. Taylor's fertile pen, one and all must read with a great relish. That (see page 307) on Rose growing, if it wanted any testimony, I could give it with perfect good faith. I have Roses now in bloom of large size and healthy, struck in the manner that Mr. Taylor so ably describes; they have been potted six years, and have a top-dressing yearly. The plants in my cutting bed are now making their young growths. I may mention that Tea Roses are not so hardy as Hybrid Perpetuals, and they require the assistance of a handlight in sharp seasons. I beg

to congratulate Mr. Taylor on the success he has achieved by sheer hard work, and hope he will live to charm us with more of his admirable notes.—R. Gilbert.

AURICULAS AT THE ROYAL NURSERIES, SLOUGH.

Mr. Charles Turner's collection of these choice old florist flowers is now in full beauty, and the pleasure of inspecting them will well repay the ardent amateur for any of the discomforts incident to a long journey. It is also a treat to have an hour's chat with that genial florist Mr. John Ball, Mr. Turner's foreman of the florist flower department; his heart is so thoroughly in his work, and his knowledge of the subject so extensive, that the most experienced cannot fail to learn something from him. There is but little new to chronicle amongst the stage varieties. Alderman Wisbey Mr. Ball believes to be the best green edge; the pips are quite circular, the tube bright yellow, paste dense and white, body colour dark; it has, however, the fault of the green edge not being quite pure, and the habit of the plant is not perfection. Hertfordshire Hero is another very good green edge not much known as yet; it was not quite out, but I noted it in Mr. Turner's collection a few years since as being one of the best; the green of the edge is purer than that of the preceding.

Amongst the *grey-edged* flowers there is nothing new that has not been already described in these columns. All the best sorts were in fine condition. Colonel Champneys stood up grandly amongst the others. It may have some defects in the critical eye of "D., *Deal*," or Mr. Horner, but as it was to be seen at Slough it is unsurpassed. The ground colour is a beautiful violet, and the pips are faultless in shape; added to this it has a large truss, and is the most easily grown of any Auricula; from a decorative point of view it is A1. Other very fine flowers were Competitor, Alderman Charles Brown, George Lightbody, Richard Headly, Unique (Dickson), and Unique (McLean).

White-edged.—Mr. Turner's collection is at present very strong in this class. Arabella (Headly) was remarkably fine; as I had seen it previously, and as it has flowered at Loxford this season, it is very similar to Popplewell's Conqueror, and like that flower somewhat goggle-eyed; one truss of it at Slough was perfection, the eye nearly filled by the anthers, and the body colour showed-up well between the dense white paste and the correct white edge. John Waterston came next to it: this flower has a very perfect truss, and as it is grown here it must certainly take its place as a white edge. Smiling Beauty was not quite out, but two trusses that would open in a week were very strong. Omega is a new flower raised here, but the trusses were rather small; with stronger plants this variety must be placed high on the list. Taylor's Incomparable, and Favourite (Gairns), Model, and Highland Queen, were very fine.

Amongst *selfs* Charles J. Perry holds the same position as Colonel Champneys does amongst the greys; it is a very beautiful violet self of very free growth. Cantab (Headly) is a fine dark self. Perfection, *alias* Mrs. Smith, is very dark with a clear white paste; many of the best selfs are in full beauty.

Alpines are now a strong section, and as the pure white paste is one of the essentials in a good stage flower, so a clear yellow paste is a characteristic of a good Alpine. The best varieties with the yellow or gold paste are Colonel Scott, very dark maroon, one of the best, and sent out this year for the first time. Diamond, another new and fine flower. Mercury, a splendid maroon crimson, flower perfect in every respect. King of Crimsons, this is another beauty, with an immense truss and pips of fine quality. Brilliant, though this is one of the earliest of Mr. Turner's seedlings, it is a fine crimson flower with fine paste. Spangle, dark crimson, with gold paste. Bronze Queen, fine bronzy crimson, very circular flower; plant of neat habit, bright yellow paste. Topaz, very large pips, yellow paste, surrounded with a broad edge of purplish crimson; a grand flower.

Certain flowers in the alpine class are distinguished by what is termed a custard paste. The lighter-coloured flowers have generally this paste; some of them are very good, and in many of them the pips are larger; they are not so attractive as those with the yellow paste. One of the best flowers of this type is a new one named Beatrice; it has large circular pips. Conspicua and Elcho, fine flowers with an immense truss. There were many other fine flowers in the alpine class, but the above are the cream of them. One very distinct and pretty flower of this class which I had from the north, named Miss Reid, I did not see here. I noticed that the plants were not placed on stages as is usual, but on a layer of coal ashes. This system must be well adapted for hot dry districts, as the moisture arising from the damp ashes is certainly conducive to the health of the plants.

There are other objects of interest at the Royal Nurseries. Long ranges of houses filled with pot Roses on the Manetti stock, other ranges with stage and fancy Pelargoniums. The houses devoted to specimen pot Roses are filled with exceedingly healthy plants; the smaller specimens are forced for the earlier shows, and would be ready in a few days. Céline Forestier seems to be one of the most constant yellow Roses; Paul Neron was very fine, and conspicuous amongst a host of beauties Marquise de Castellane stands out proudly; and while the Duke of Edinburgh is one of the best dark flowers, the Duchess holds a proud pre-eminence amongst the lights. Capitaine Christy is also a fine light flower.

The large specimen Azaleas which I saw on the occasion of my last visit have been disposed of, and smaller, though quite as interesting, specimens have taken their place. There are some excellent standards in full flower, which will doubtless be seen at some of the exhibitions. They are trained umbrella fashion, and are exceedingly effective.

Amongst the newer sorts, which ought to be in the most select collections, are Madame Louise de Kerchove, bright salmon, edged with white. Comtesse de Beaufort, large bright rose flowers of great substance, densely marked on the upper petals with crimson spots. Apollo, white, very sparingly striped with red; a fine large flower. Charmer, rosy purple, very large flowers. Mdlle. Leonie Van Houtte, white, the upper petals marked with greenish spots. Mdlle. Adelina Patti, white, with red stripes. Princess Louise, salmon, edged white.

The spring bedding is at its best, and altogether the Royal Nurseries are well worth a visit.—J. Douglas.

THE CULTIVATION OF HALF-HARDY ANNUALS.

By these are meant that class of annuals which are grown in the open air during the summer season for flowering in the autumn. They are a class of flowers distinct from the hardy annuals, both by their more massive and imposing flowers, and by their longer continuance in bloom. In this respect they may almost be regarded as bedding plants, as when once the beds are filled, the flowers will continue until destroyed by frost. They are adapted for autumn decoration especially, and in this respect are not open to the reproach of hardy annuals in being weedy in their habits and transient in their beauty. Yet they are not suggested in any way as rivals to the bedding plants proper, but they are recommended as substitutes where substitutes are needed, and also as auxiliaries to the more varied and complete floral adornment of the surroundings of our homes.

No fault is found with those whose ideal of decorative taste is represented in the stereotyped patterns wrought by pigmy plants into designs borrowed from Brussels carpets or Indian shawls. Many of these designs are exceedingly chaste, and are marvels of taste, patience, and skill, in the highest degree creditable to adepts in this art—for art it is—of garden embellishment. But the mode is not adapted to all—not, indeed, to a tithe of English gardens, and if it were it is not at all certain that their interest would be greater or their beauty more really enjoyable and satisfying by the overwhelming sense of artificialism which would pervade them.

It can hardly be denied that a characteristic of the times is to foster a taste for mere copying and imitation amongst gardeners, and which is occasionally carried out, or attempted to be, in places and under circumstances which invite at the best but a partial success, and often a certain failure. Better by far would it be to first accurately measure the resources of a garden, and on these resources base a line of action, than to attempt to imitate every latest fashion of the hour, and seek to import it where it is unsuitable. Under this great governing principle of mere imitation a monotonous sameness is enveloping our gardens, and which results, in innumerable instances, in half-finished attempts at aims to be grand, and a conviction throughout the season that the reward, at the best, is an imperfect work. It can never be really satisfying to

owner or gardener to feel that the best they have to offer is a poor copy of the same idea which is perfected in half a dozen gardens which the visitor has seen in as many days' travel. Far more enjoyable is the feeling which arises from the fact that a system has been followed, and which circumstances have permitted to be carried out fully and well.

Such a garden does not tell one on the face of it that we have aimed at something beyond our power and have failed, but it at once impresses a feeling that correct judgment and good taste have been exercised, and that the fare which is offered is the best of its kind. A garden of such a nature is sure to be enjoyed, let the style of its decoration be of what pattern it may. A garden of hardy flowers, interspersed with plants of sweet odour, and brightened by half-hardy annuals, is, providing all are grown well, certain to command admiration, and is altogether more creditable to the owner and more decidedly enjoyed by his visitors than is an elaborate endeavour to ape a style which has ended in a grand example of patches, and a patent conglomeration of futile attempts.

It is unquestionable that what is known as stylishness has, of late, driven the beautiful and sweet plants of tender annuals out of many gardens. These plants are nevertheless still worthy of the room they occupy, and will add a feature of interest and a measure of enjoyment wherever they are cultivated. They are also a class of plants easy to fall back upon to that large body of persons who lack a full supply of other bedding plants with which to fill their beds and borders. They are, in fact, the best of all substitutes for what we call bedding plants, and are easily raised in any required quantity. But is it not late to recommend the raising of them now? The reason why that is a natural question is, that now-a-days it is so much the custom to raise plants in pots and grow them on under glass for planting-out, that a plant is hardly considered to be worthy of the flower garden unless it has undergone the regular period of nursing.

The plants in my boyhood days had no such tender treatment given them. They had not then to undergo a term of coddling probation, and yet we had such beds of Stocks, Asters, Zinnias, Dianthuses, Marigolds, Amaranthuses, &c., as are seldom met with now. The fact is that seed sown during the first week of May will produce splendid sturdy plants, which by steady unchecked growth will fully equal, if not surpass, those which had been raised two months earlier and had been nursed on tenderly under glass. I quite agree with Mr. Allis (p. 334), that if a glorious row of Ten-week Stocks is coveted, few, if any, modes can surpass that of sowing the seed thinly in a drill, and there letting the plants remain to bloom. Thus sowed at the time stated in rich deep soil, and the single flowers drawn-out as soon as seen, will leave a massive row of double Stocks that cannot be surpassed by sowing under glass and subsequently transplanting the seedlings. All the tender annuals may be sown with confidence in a natural manner at this season of the year, with the certainty that they will give a splendid return in the autumn of healthy plants and enjoyable flowers.

It is easy to make up for what may be thought late sowing by rich soil and generous culture. The seed bed especially requires to be good. A sheltered site in the open air fully 6 inches deep of rich light soil will raise such plants as those above-named as it is impossible to equal by sowing in pans under glass in March. Everything depends on the seed bed. It should therefore be composed of prepared soil either with or without a gently heating base of manure. Such soil should be composed of quite half of old mouldy manure or leaf mould, and the rest sandy loam. Sow in a bed of that kind Asters, for instance, early in May, and by no other means known can finer Asters be produced in the late summer and autumn months.

The Aster is an autumn flower *par excellence*, and injustice is done it by sowing early and compelling it to bloom prematurely in the sultry days of summer. Asters, like Celery, must have heavy autumn dews to bring them to perfection. In every garden in the land ought Asters to be sown at the time and in the way stated, and then, other points of culture being correct, splendid blooms will follow as a matter of course—such as will raise the flower in the repute it is worthy to enjoy. Asters as autumn flowers are sadly neglected. All the varieties are good, and some are really splendid both as to colour and perfect symmetry of bloom, but they are spoiled by the fashion of sowing them too early, and subjecting them to the tender mercies of checks by drought, and crowding, and insect feastings.

By this natural mode of raising the plants we have had no lack of splendid Asters, glowing Marigolds, brilliant Zinnias, and pendent blooms 3 feet long of Amaranthus caudatus for harvest festivals when a first-fashion garden could contribute nothing for that joyous time. These are the flowers to grow for cutting when flowers in autumn are so often required in quantity. Let them have a place; carpet, and cushion, and enamel, and panel, if need be. Not a word is said against it, but only against the slight that is being given to cheerful-flowering plants of the garden by all-devouring "style" and picture-growing "effect."

Helichrysums and other Everlasting Flowers are all amenable to this easy natural mode of culture, and by it autumn flowers may be had in prodigal profusion. Permit them at least to have a share of attention, and let us do away for ever with the complaint of a noble lady who had fifty thousand plants "put out" in her garden, and who had no flowers to cut to enliven a festal scene.—A Surrey Gardener.

PEACH FORCING.—No. 4.

Resting Period.—No amount of frost so far as I know will injure the well-ripened wood and buds of Peach trees. The lights, therefore, I advise to be removed, from the house being put in order to forcing commencing; but some object to this, as the house is wanted for other things. "Other things" very often mean plants which cannot endure cold, which is what Peaches require for perfect rest, they not being subjects of the tropics where dryness corresponds to the cold of the temperate zone, and the warmth thus given also means dryness, whereas the Peach at rest requires cold and a moist soil, and even should the latter be given the warmth causes them to start prematurely, the buds to swell, and blossoms to expand irregularly and weakly. I know many, and I may say most gardeners are obliged to have plants in fruit houses which they know be inimical to the successful culture of the fruit trees, and to keep the trees cold or remove the lights would be to deprive their employers of a number of plants or their flowers; hence the laudable endeavour to please is often only a cause of disaster to the Peach crop, which is put on the back of the cultivator, and not in anywise attributable to the wish on his part to meet his employer's behests, contrary as they may be to success in the object to which the structure is devoted.

Peaches are grown in houses that are cold, so far as it relates to frost being only excluded, or a minimum of 35°, which is all very well if it could be done without fear of the 35° being not oftener 40° or more, a temperature more frequent when 35° is aimed at, for who can tell to a few degrees what heat will be required to keep a house at so low a minimum on a cold morning without allowing a margin for emergencies? I could never act up to such niceties; better say keep as cold as possible and exclude frost. Better far admit it for two reasons—the rest is more complete, and the trees do not require so high a temperature to excite them when forcing is begun; and a third is the enhanced healthfulness of trees rested cold, as compared with those rested in a temperature sufficient to excite into growth those which have been kept cold.

Further remarks must be made as to the period of rest. In no case ought the period from the fall of the leaves to forcing commencing be less than six weeks; if twelve weeks elapse all the better. For early forcing the latter time can hardly be allowed, for the earliest forced trees will not lose their leaves until the early part of September (and to remove them before they part readily from the tree by a light brushing in an inverse way to growth is not sound practice), so that with forcing commenced early in December the trees can hardly have more than ten weeks' rest, as the house will be closed ten days to a fortnight before fire heat is applied, and from closing the house dates the forcing, for if no fire heat be applied natural heat is retained, or cold warded off by artificial means. Trees which have been regularly early forced will have the wood ripe at an earlier time than is named, and if the soil is kept moist they have a tendency to secondary growth, and will even blossom to some extent and set the fruit. Dryness even in a case of this kind I do not advise, and yet it must be resorted to, but not to the extent of what is known as dryness compared with Vines, for the soil for Peaches should never be so dry as to cause the leaves to become limp. Care, therefore, will need to be taken so as to have due moisture in the soil without being sufficient to promote growth. We must also keep the house as cool as possible, and the foliage healthful.

Then we have to guard against premature swelling of the buds, as in a warm and moist autumn trees which have fruited early and been at rest some time are liable to be excited even when exposed. The best thing for retarding the growth is to cover the house, in place of the lights, with straw shutters—lath frames covered with straw, closing the house during the day, but having top and front ventilation at night. This will keep the trees cool and ward off the sun, which dormant Peach trees cannot long endure without the buds swelling. The straw shutters may be removed in dull weather, or remain on until replaced by the lights. It ought also to be borne in mind that the water in the pipes for heating will, if frost long continue and be severe enough, freeze, and may crack the pipes. Either they must be empty at such a time, or the valves raised a little, so as to warm the water and prevent freezing. I will conclude the introductory observations by stating the border outside is to be covered with 6 inches of fresh rather short stable litter and leaves; the inside border thoroughly watered when the lights are put on, and the house closed.

Period of Forcing.—The time from closing the house to the fruit being ripe somewhat varies as bright or dull weather prevails. The period usually extends over five months, or less if the season be propitious. A house closed at the middle of November will have the fruit ripe at the close of April or by the 1st of May with the old kinds; but with the Early Beatrice and Early Louise Peaches, the end of March or early in April. Those kinds under the same conditions as Royal George and others being rather more than a month earlier than the old kinds. The house closed the middle of December the fruit is ripe at the end of May or early in June; at the middle of January the crop is ripe at the end of June or early in July; middle of February will give ripe fruit towards the close of July and early in August, and these will be followed by those on walls or in houses having no artificial heat, only to secure the safety of the blossom and young fruit from frost, and it may be the ripening of the crop and wood in an unfavourable summer.

Temperature.—After the lights are put on and the house closed, no artificial heat is to be applied the first fortnight, so that forcing proper will commence on the 1st of the month ensuing that of the closing of the house; but the temperature ought not to be allowed to fall below 35° at night, nor must it exceed 40° by artificial means. After or during January trees previously forced will have the buds in a forward state; they nevertheless are to be kept cool the first fortnight, admitting no air until, by sun heat, 65° is registered; but if so far advanced as to be in flower, they must have the temperature as hereafter specified. After the first fortnight the minimum night temperature 35°, maximum 40°; day minimum 45°, maximum 50° by fire heat; sun heat 65°. The application of the fire heat should be gradual, those temperatures not being attained until the close of a week after applying it, still gradually increasing, so as to have the temperature at the end of another week, when the blossoms will have in part expanded. Fire: day 55° maximum, 50° minimum; night 45° maximum, 40° minimum; and sun 65°. These to be continued until the fruit is set and begins to swell, when the day temperature from fire heat is to be kept steady at 55°, night 50°, morning 45°. A short time only will elapse ere it will be seen what fruit is going to remain on until the stoning process—some will swell quickly to the size of horse beans, whilst others will remain the size of peas, and grow no larger, but drop. The temperature at this stage may be—fire: day maximum 60°, minimum 55°; night maximum 55°, minimum 50°; sun 65°, to begin admitting air, advancing to 75° or 80°, not exceeding the latter without full ventilation, nor 75° without full top or back air. We continue at the latter temperature until we see which fruit is going to stone, and as some may cease swelling and drop, know those remaining are undergoing that process, and will remain, so far as swelling is concerned, almost stationary.

So soon as this is completed, which may be known by trying a fruit with a knife, after a fortnight or three weeks of the standstill state of the fruit, or when the fruit again commences to swell, it may be taken for certain the stoning is completed, and the temperature be gradually raised by fire heat—day 65°–60°, night 60°–55°, sun 75° to 80° or 90°; and by the close of another week fire heat by day 75°–70°, night 65°–60°, sun 75°–85°–90°, and continue until the fruit is ripe.

After all the fruit is ripe the trees must not be exposed too suddenly to a lower temperature, but it may be gradually lowered as regards the night temperature, securing to them a minimum of 55° by artificial means, until it is afforded by natural heat.—G. Abbey.

THE SPRING BULBS IN HYDE PARK.

Though it is not in my power to write a very glowing description, a few plain notes may probably be of some little interest. Mr. Luckhurst's notes show that bulbs in Sussex are much earlier than here. Hyacinths can scarcely be said to have arrived to their full beauty, while of Tulips but few kinds are in flower.

As in the case of summer bedding, the principal masses of colour in Hyde Park are in the beds running parallel with Park Lane, between Stanhope Gate and Grosvenor Gate. The beds are on turf in a double line. The whole of the double line of beds are planted alternately with blue, white, pink, or red Hyacinths, varying, of course, in shades of colour; each bed or each pair of beds being devoted entirely to one colour. All are edged with Crocuses, now out of flower. On the whole, these beds have a very pretty and pleasing effect, especially at a short distance, as on closer inspection one discerns a few faults in the way of gaps and unevenness in growth.

The Tulips, which occupy the single line of beds, are altogether wanting—at least at present, being backward, and are much disfigured and crippled in foliage, the effects doubtless of the long and severe cold. There are here only three varieties well in flower—namely, Vermillion Brilliant (which is dwarf and good in point of colour), Keyzers-Kroon, and White Pottebakker. Some little allowance of course must be made for the times of flowering, as spaces will always intervene between them more or less according to the selection.

Adjoining the Albert Gate, where the Palms and semi-tropical plants are usually placed, are some few beds of mixed Tulips, very good, being well flowered, with fine, strong, healthy foliage; attributable, no doubt, to the somewhat more sheltered position.

I shall not name the several kinds of Tulips which are not in flower, but will give you the names of all the best Hyacinths. These are—Bouquet Tendre; Regulus, extra good; Diabitz Sabalskansky, good colour, uneven in growth; Baron Van Tuyll, fine spike; Grand Vainqueur, very good; Robert Steiger, very good; William I., very dark and good; Eclipse; L'Ami du Cœur, fine violet blue; Crown Princess; Charles Dickens, immensely large spike; Mimosa, deep blue or black; Amy, pretty, but rather small; Grandeur à Merveille, extra good; Uncle Tom, very dark; Queen Victoria, one of the best, and I think may be fairly called the best of this batch; La Candeur, dwarf and good; Bleu Mourant, good; Anna Maria, double, almost if not the only double, and well that it is so, as it will bear no comparison with single varieties of its colour.—C. Martell.

PROTECTING POTATOES.

Now that morning frosts are prevalent, and many tender plants are in danger of being cut off, I would mention a simple plan whereby I have more than once saved my early crop of Potatoes. This is a crop of great value, and worthy of a little extra trouble to secure it at the earliest possible date, and also in profitable quantity. Frost not only throws the crop backward, but lessens the bulk considerably. When first appearing above ground the simplest plan, perhaps, is to draw the soil over the leaves. Eventually they grow so high as to render this impossible, and still they are endangered by late frosts. The first crops are generally planted in short rows across south borders, and are then easily protected by boards. A lath stuck in the centre of the rows, one at each end, and two boards set on edge, one on each side of the row and leaning against the lath, forms a wooden roof under which the Potatoes are safe from 10° of frost. It is a very simple old-fashioned plan, but on that account is none the worse. Any sort of old boards, 9 inches or more in width, will answer; but, it may be added, the use does no harm to new boards, as they are only required for a week or two. In the morning they are just thrown one each way, and lay flat between the rows, or they may be ridged on edge, which takes up a little more time. The advantages are—the Potatoes are quickly covered and uncovered, and are quite safe from any ordinary frost. I have proved the plan effectual, and hence I recommend it.—Amateur.

THE BLACK POPLAR AND THE ASPEN.

You ("A. F."—a correspondent) have been correctly advised to plant these as quick-growing trees, with light-coloured foliage that will be effective in front of the dark-leaved Conifers in

your plantation. It is quite true that these two Poplars usually grow largest in moist soils, but they are cosmopolitan; they will thrive in almost any climate and any soil. We have seen both of them growing as large and as handsomely formed on a dry calcareous soil as the Black Poplar represented in the accompanying engraving. You may easily discern without any danger of being deceived which is an Aspen, not only by its leaves, but more certainly still by its inflorescence, of which we now publish an engraving. The leaves of the Aspen are roundish ovate, the edge slightly wavy and toothed, downy

Fig. 84.—Black poplar.

when young, but quite smooth when full grown. The leaves of the Black Poplar are deltoid-pointed, toothed, with glands at the base of the teeth, and always smooth on both surfaces. We add a few notes relative to each species.

Populus tremula, the Trembling-leaved Poplar or Aspen, is a native of most parts of the British Islands, and is described by all our earliest herbalists, but by none in such scandalous terms as by old Gerarde, all of whose female relatives must have been scolds, he says it "may be called Tremble, considering it is the matter whereof women's tongues were made, which seldom cease wagging." The continuous tremulous motion of the leaves arises from the even balancing of their discs, and the length and slenderness of their footstalks. Its popular name is derived from the Anglo-Saxon, and refers to that motion. Æpse was its Anglo-Saxon name, and the same word is in that language synonymous with our "tremulous."

Superstition has given birth to a legend, at one time prevalent in the Highlands of Scotland, and thus told by Mrs. Hemans. The Cross—

> "Was form'd of aspen wood: and since that hour
> Through all its race the pale tree hath sent down
> A thrilling consciousness, a secret awe,
> Making them tremulous, when not a breeze
> Disturbs the airy thistle-down, or shakes
> The light lines of the shining gossamer."

In dry soils it does not attain a greater height than 50 feet, but in moist situations it is often full 80 feet high. It is not a long-lived tree, usually beginning to decay when seventy years old, and this, with its tendency to produce numerous suckers, renders it not desirable for ornamental planting near a lawn or flower borders. The wood is white, soft, and light, and is used by the turner for forming bowls, trays, and other utensils. It was so valued for making arrows that in the reign of Edward IV., 1464, a statute was enacted from which the following is extracted:

"Patten makers may make pattens of such Asp as is not fit for shafts.

"Asp timber is the best and lightest timber, thereof to make pattens and clogs, most easy for the wearing of all estates, gentiles, and other people, of any timber that groweth.

"Turners, carpenters, woodmongers, and cole-makers do occupy, expend, and waste yearly in their occupations a great quantity of all manner timber of Asp."

Populus nigra, the Black Poplar, probably so called because of its darker tints than those of the White Poplar. Its bark is browner, and the leaves have no white down on their under surface. It attains a height of 80 feet, and its wood is one of the best for making turnery ware. It has been much used for flooring, and Mr. Young tells that it is so slow in taking fire that the flames were stayed at that part of a building on fire constructed of this wood. It affords pasturage for bees, both by its catkins and the honeydew which is freely secreted on its leaves.

NOTES AND GLEANINGS.

The following information for intending English exhibitors at the forthcoming International Horticultural Exhibition at Cologne, to be opened on the 25th of August next, has been sent to us for publication. The Netherlands Steam Navigation Company and the Belgian Company, whose steamers ply respectively between London, Rotterdam, Dover, and Ostend, as well as the Rhenish Railway Company, have reduced the freight on goods to be sent to the Exhibition by 50 per cent., and no duty will be charged on such objects unless they should be sold in the country.

—— On April 7th a deputation of the subscribers to a testimonial to Mr. Lees, late of Tynningham Gardens, met with him in Edinburgh, and presented him with a handsome gold watch and chain and a silver tea-service, as a manifestation of the high esteem in which he has for many years been held as one of our very foremost cultivators of plants and fruits, and of his exemplary character as a man. Mr. Methven, nurseryman, occupied the chair on the occasion, and the formal presentation was by Mr. Thomson of Tweed Vineyard. We trust Mr. Lees may long be spared to enjoy the articles of presentation as well-deserved tokens of ability and character.—(*The Gardener.*)

—— Two Useful Books have just been published. One of them is "The Narcissus, its History and Culture, with coloured plates, and descriptions of all known species and principal varieties." The author is Mr. F. W. Burbidge, and there is added a scientific review of the genus by Mr. J. G. Baker, of the Royal Herbarium, Kew. The coloured plates are excellent. The other book is "Pruning, Grafting, and Budding Fruit Trees." The author being Mr. D. T. Fish, insures that the details are reliable.

—— The following tells the wages of a head gardener 503 ago. In 1372 John of Gaunt issued a warrant, which is still in existence among the archives of the Duchy of Lancaster. It is addressed to his Receiver-General, and having recited the engagement of one Nicol Gardiner as "nostas gardyner"—the surname and the office being differently spelled—for "nostre manoir de la Sauvoye," it proceeds to define his duties and emoluments. Nicol, we observe, is to have all the fruits and "herbages" for his own profit, saving only what is required for the household, but is to manure and work the garden at his own cost and charges, and to provide all things needful, "busoignable," for its due cultivation. The Duke, on the other hand, stipulates to provide him with rails and fences for the railing season, "en temps de raillement," and for wages commands the Receiver

to pay him the sum of twopence a-day whilst he is retained as gardener; or, in the old Norman French of the period in which the warrant is written, *deux deniers chaseum jour le temps qu'il serra ensi gardyner.*

—— Frosted glass, useful for screens, &c., is made by laying the sheets horizontally and covering them with a strong solution of sulphate of zinc. The salt crystallises on drying.

—— All the Teas, green and black, and every variety however named in the market, are the produce of one shrub, the Thea viridis. The variations of colour and flavour arise solely from the different soils and climates where the Tea is grown, and from the different modes of manufacturing it. The preparation of green Tea may be described in general terms as follows:—The leaves are gathered from the shrub and placed in bamboo baskets; they are then put into shallow iron pans, placed over charcoal fires, and stirred continually and briskly, the rising steam being fanned away; after this they are removed from the pans, and whilst still flaccid with the contained moisture are placed before the twisters on a table made of split bamboo, and therefore presenting ridges; the twisters roll them over with their hands until twisted. The leaves are then spread out and exposed to the action of the air, and afterwards returned to the drying-pans, exposed there to additional heat, and kept continually stirred until the drying is complete, when they are picked, sifted, sorted, and so prepared for packing. Black Tea is prepared in the same manner, with this difference, that the fresh leaves, as soon as collected, are thrown together into heaps, and allowed to lie until a slight degree of fermentation ensues, or a spontaneous heating, similar to that which takes place in a damp haystack. This partial fermentation of the Tea leaves darkens their colour. All the black Teas are grown at Fokien, a hilly and populous district about two hundred miles to the north-east of Canton. The green Teas are raised in the district of Kianguan, about 750 miles from the same city.—(*Cassell's "Technical Educator."*)

OUR BORDER FLOWERS—ANDRYALA LANATA.

For years past we have been seeking for plants for various purposes for spring, summer, and autumn decoration. I have sometimes thought, Why has not the plant bearing the above name been brought into requisition? Is it because it was introduced to the notice of our forefathers as long ago as 1732 that it may be thought too old to have a place in these days of modern gardening? I am not aware that the services of this plant has ever been much in request, at all events we very seldom meet with it. Should any feel disposed to acquaint themselves with it, they will not only find in it an old friend but a very good new one.

It is a very choice plant, said to be hardy, which it may be in some favoured localities; but it is not safe to be too venturesome if you mean to continue acquaintance with the plant. I find it to be about as hardy as Centaurea candidissima. Sometimes it passes through the winter, sometimes not. I like it best from seed sown in the summer in gentle heat, and when large enough to handle the seedlings may be potted into small pots in a light sandy compost, be grown-on in heat for a time, hardened off in the usual way, and be kept in a cold pit from frost. In the following spring they can be planted where required.

The plants may be increased by division and also by cuttings during the summer and early autumn. They require thorough drainage, but should not suffer from want of water. A compost of sandy loam, peat, and leaf mould will suit them. They are impatient of damp. The plants continue for a long time in flower, and are useful where cut flowers are in request. I have not tried the flowers, but I have an impression that with care they might be dried, and be turned to good account when flowers are scarce and in demand. This plant should have a prominent place in all our borders. (This is now called Hieracium verbascifolium.)

SOAPWORTS.

With the exception of two or three species the Saponarias are seldom met with in our herbaceous borders, and are little known in general cultivation. We are in possession of one of this family as a native plant. It is sometimes met with on the banks of rivers in shady places. It is considered by some to be rare, but is more local than rare, as when met with it is pretty abundant. It has the merit of being one of our autumnal-blooming plants, and on that account it is the more desirable. Saponaria officinalis has done duty on the exhibition table during the autumn both as a native and herbaceous plant. S. officinalis plena is sometimes met with in cultivation. Naturally they are not what is termed good-habited plants, but in semi-wild situations in moderately good soil they will for the most part take care of themselves. They are not well adapted for the dressed border on account of their rampant growth.

There is a great contrast between members of the same family, for while Saponaria cæspitosa grows only 3 or 4 inches high, S. officinalis grows as many feet, but the former requires more care than the giant form. It likes a cosy nook on the rockery, and should have good sandy peat and loam with knobs of sandstone mixed with it to grow in. It requires moisture, but must not be drowned. It is well worthy of cultural care. S. luteum is another diminutive kind, and requires the same treatment as the preceding; having yellow flowers makes it more desirable. S. caucasica flore-pleno is a very choice border plant; planted in good loam mixed with leaf mould and sand, when well established it will attain the height of 2 feet. It flowers for a length of time.

S. ocymoides is the best of the family; it is of dwarf prostrate habit, well adapted for overhanging ledges of rockwork, baskets, or edgings. When well established it lasts for some time. It may be increased by seed. In some soils I have known plants die off without any apparent cause. I prefer renewing them yearly by cuttings during the summer. They strike freely in sandy soil under handlights or in cold pits in a shaded position. When rooted they should be potted and plunged in ashes till wanted to plant where they are to flower. This is one of the very best plants for the spring garden that we possess; no plant can surpass it as a bedder or for bordering. It should have a free porous soil and a moderately dry situation, but should not suffer from want of water. There are others that ought to be found in more general cultivation. The smaller species may be increased by division, but this is attended with danger to the plant, which requires very careful manipulation, or there is a fear, after the operation, of the plants going off, and then there is sometimes a difficulty of replacing them.—Veritas.

WATERING PLANTS.

THE WATERING POT, ITS USE AND ABUSE.

This is a subject that at this season of the year claims the attention of gardeners and amateurs. Those who have large supplies of bedding-out plants to prepare know full well what a heavy task the watering is after a sunny day. The few remarks I have to make are on the indiscriminate use of the watering pot, and they apply chiefly to bedding plants. As a rule the watering of such plants is done with a rose watering pot, for the sake of despatching the work as quickly as possible. I dare say that many know well what the after-consequences are likely to be if the practice is carried on for any length of time. Perhaps some may say, "Unless we water in the way described we should not complete the work in anything like reasonable time." No doubt that is a prevailing idea, but it is at times destitute of force. I fully admit that the task of watering is a heavy one and will often tax the energies of those who have such work to perform.

Suppose a young man is set to work on a mixed collection of bedding plants, if he is not provided with two large watering pots and a smaller one he ought to be, unless there happens to be a good supply of water close at hand. As a rule the first performance is the rose pot set to work in right good earnest right and left; whether the plants require it or not, all must submit to the same proportion of water. But the next question is, Do they all receive it? I will, for instance, take a well-established Geraninm with a good bushy head for a test plant. By watering on the heads of such plants it will be found that at least half the water will run off, while Calceolarias, Verbenas, and a host of plants are apt to become water-logged; the soil is soured, the plants begin to turn yellow, and ultimately they sicken and die. I have seen many Calceolarias and Verbenas so ruined, but when this appearance presents itself to the eye the wonderment is, Whatever can be amiss with the plants, for it is not for the want of water? That may be very true, but it is owing to having had too much water. After the watering is finished some will say with pride that they have completed their work in such a short space of time, but not thinking how many plants they have injured, and, it may be, given the fatal draught.

These remarks are not directed to the practical gardener, for he will know at a glance how matters stand, but it is to the tyro that they may be of some service. I may be asked if it is wrong to water heavily with a rose pot, and what plan ought to be adopted. Simply as follows:—Have a small watering pot with not too wide a spout, and single out each plant for watering. Apply the water carefully, not standing upright and pouring it in at random and washing half the soil out of the pots. Try this plan against the flushing system with the rose, and make a note of it as to how much time is occupied by such a plan. Suppose the water has to be carried some distance, this will entail much extra labour, which by judicious watering is avoided, there being less water to carry; and this I think will be found to balance favourably against the extra time it would require in watering, besides being much better for the plants. By this plan only those plants have water that require it. There are times when the rose may be judiciously used if it is thought desirable, but not oftener than once in two or three waterings, unless the weather should be very hot and dry. But many will have to be guided by the supply of water, for in some places it is a very scarce article.

The nature of water to be used is a great item in the well-being of plants. We all know that rain water is the best where we can obtain it, but how often do we see the supplies drawn from the indispensable garden pump, as hard and as cold as it can well be? This of itself is a sufficient cause to make plants look sickly. If spring or well water is the only available supply it should be pumped up into some tub or cistern at least eight or ten hours before it is used, so as the action of the air and the sun may warm it; but so many work on the penny-wise and pound-foolish plan that such necessaries are often lost sight of.—G. R. Allis.

NOTES on VILLA and SUBURBAN GARDENING.

The Amateurs' Greenhouse, Vinery, and Frames.—At no period of the year are the above structures found so serviceable as at the present time, and speaking generally, I think that at no season is it more difficult to manage the plants grown in them, because it is yet too early to trust safely the bulk of bedding plants out in even sheltered spots without ample protection. The keen frosts we have lately had, especially on the morning of the 25th, warns us against the too early transition of tender flower-garden plants from the protection of the houses. Consequently the greenhouse must of necessity be very much crowded with plants that would do elsewhere if room could be found for them. Assuming that in this house there is a mixed collection of plants in and out of flower, it will be advisable to always admit plenty of air both front and back if a lean-to house, or at the top and both sides if a span-roofed structure.

It will be well to put on a slight shade over the sunny side of the roof, either by a thin blind which can be rolled up and down at pleasure, or by a thin coating of a mixture of whiting and milk, or, in the absence of the latter ingredient, add a handful or two of finely-sifted quicklime, just sufficient to make it cling to the glass. If too much of this is put in it burns as it were on the glass, and it is most difficult to wash-off again. I mention this plan not because I consider it the best, but in the absence of a blind some sort of shading is necessary for such plants as Azaleas in bloom, Camellias making their growth, and also the most of the greenhouse Ferns. The Azaleas should be kept in the coolest part of the house, where they ought to last in bloom for some time. Camellias growing should if possible be grouped together so that they can have separate treatment, which should be a gentle syringing morning and evening. Water freely at the root, and occasionally use clear liquid manure.

Heaths of the hyemalis, or winter-blooming varieties, should be cut-back at once if not already done, and as soon as they break into growth again let them be potted, giving them a sandy peaty soil with a very little finely-sifted loam added, and powdered charcoal. When they are advanced sufficiently afterwards they may be placed outdoors for the summer, taking care that the sun does not play too strongly upon the pots, which is injurious to their fine hair-like roots. When potting them the nature of their roots requires that the soil should not only be thoroughly well mixed-up by the hand so as to ensure a proper distribution of its ingredients, but it should be made very firm, the fine roots are then more likely to take hold of it. Epacrises out of bloom must also be cut-back considerably, say to within an inch or two of the old wood. When these break again treat them the same as Heaths.

As to the potting of Azaleas and Camellias, I always shift them while they are making their young growth, while others practise such work when they are setting their flower buds—that is, just as growth is finished. In a greenhouse, where so many plants have to be grown, it is best at this time of the year to place all the blooming plants by themselves, reserving a place to group all young growing plants and those that want different treatment. They will then have the chance of receiving the treatment they require.

Fuchsias should be at once shifted and grown-on for autumn blooming; they will require moisture overhead and frequent stopping of the shoots. They will also, if well drained in the pot, need an abundance of water at the roots. If it is necessary to have a few in bloom earlier than the rest leave off stopping them, and they will soon flower. Balsams, Achimenes, and Globe Amaranths may be associated with the above, also Coleuses, Hydrangeas, Gesneras, and Gloxinias.

In vineries which have been allowed to come on naturally the Vines will now require attention in thinning out and tying down the shoots to the wires. This process requires care, for the shoots are very brittle, and if tied down too low at first many of them will snap asunder, causing a blank that looks badly and cannot well be filled up afterwards. As soon as the bunches are well out clear of the shoot, sufficient to see what it is likely to be, stop the shoots one or two joints beyond it, and as the extremity of this will break again stop this one joint beyond that again, that will be leaving one joint and one leaf at each stopping, which is plain enough for anyone to know how to do it; in these matters one can scarcely describe in too plain terms. A little fire heat at night will be required to keep up a temperature of 60° at night, which it ought to be now, and about 70° or to 75° by day. Close the house with sun heat by half-past three P.M., and towards the latter end of this month an extra half hour may be taken, and in the next month a little air all night will be an advantage. Of course moisture in the atmosphere and over the foliage at closing time is a necessity to keep in check that dreadful pest the red spider.

There is another matter of the greatest importance in Vine-growing, and that is not to delay the stopping of the shoots too long, for when so much has to be taken off at a time it gives the Vines a check and injures them. If the stopping is attended to it can be done efficiently with the thumb and finger, and with ease. The foliage left will thrive amazingly, and become both strong and large. The strength of the bunches and the size of the berries are much improved by a timely attention to this essential practice.

Now we come to the garden frames, which of course will be crammed with bedding plants; these must of necessity have all the air possible according to the weather, so as to shift the plants under protection to outdoors as soon as possible. This will give room for such plants as Chrysanthemums, Cockscombs, young Fuchsias, Balsams, and the preparation of Chilies and Capsicums, ridge Cucumbers, and Vegetable Marrows for planting out as soon as the beds can be made ready for them; in fact, I assume that all these are in their seed pots and ready for potting off as spaces are cleared for them. Then there are Melons, such as Little Heath and Beechwood, two good sorts for an amateur to grow; and frame Cucumbers, such as Cooling's Derbyshire Hero or Lord Kenyon's Favourite, should be planted out on beds of mild heat, and grown on quickly. Primulas, Cinerarias, and many other plants for which the frames will be required grow freely at this time of the year if only the proper attention is bestowed upon them.—Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

A continuation of such fine mild weather as we are enjoying at present will answer admirably for all sorts of out-of-doors fruit trees. A steady frost on calm nights when the ground is dry does not injure the blossoms much if it is not more than 2° or 3°; but on Sunday morning, the 25th, the thermometer on the open lawn fell to 24° Fahr., or 8° of frost; the early Potatoes under a wall with a west aspect, and which had been exposed on three previous nights to 4° of frost apparently uninjured, succumbed to a frost so severe as this. The blossoms on Currant, Apple, Pear, and other trees that were in flower do not seem to have suffered from it; indeed not a leaf or petal was browned. Many persons advocate shaking a little rough hay over Currant and Gooseberry bushes when they are in flower, the late Mr. Robert Fish amongst them. It causes the garden to look untidy and scatters the seeds of different grasses and strange weeds over the ground, which more than balances the advantages of the practice.

There is now a good opportunity to look after the different insect pests that attack hardy fruit trees. The Gooseberry caterpillar may be readily hand-picked in its early stages of development, or the affected parts dusted with white hellebore powder. If the mould under those bushes known to be attacked the previous season had been removed to the depth of 3 inches, and some fresh rich soil put in its place, the pest would have

been destroyed, and the bushes would be much stimulated by the surface-dressing. The caterpillar of the Lackey Moth will also be on the move, but if previous instructions as to looking out for the eggs at the winter pruning has been attended to, most of them will have been destroyed.

For a number of years the huge caterpillar of the Goat Moth was very troublesome; it had been long unmolested amongst the old trees, and from these many of the branches and even main stems of the young trees were destroyed. They bore into the centre of the young branches and work upwards until the part of the branch above the place attacked is destroyed; they can, even if deeply embedded in the trees, be killed with a piece of stiff wire. A fine Weeping Elm tree was killed by them. The tree was attacked at its base, and before the place was observed the mischief had been accomplished. As many as a score of specimens of the caterpillars were hooked out at once, and many more subsequently. An old Privet hedge was also a large pasture ground for them, and it soon became unsightly by the larger branches dying. The best way to eradicate them in this case also was to cut over the branches attacked as soon as they were observed.

The small bud worm that attacks Roses is very prevalent this season, and is also to be found on Morello Cherry trees. The young shoots are much checked in their growth by it. Hand-picking is the only remedy; but though tedious it is effectual. Many gardeners know quite well how to destroy the natural enemies that attack their crops; that is not the difficulty. At this season how to find time to have all the work forward is the question. What with crops to be put in for succession, attending to those that were put in early, and the immense number of bedding plants to be watered and moved about in May, fully employs the time of all the available labour. However much requires to be done, the best way to get through with it is not to try to do everything at once, but to do one thing at a time, and do it thoroughly.

Ran the hoe through Strawberry and Raspberry quarters. It is of great importance to have all permanent crops well hoed and quite free from weeds before they are too far advanced in growth, or they may be injured by working amongst them. If it is intended to grow the Strawberries for exhibition they must be well thinned-out, leaving about twelve or eighteen fruits on each plant; but this must not be done too early, at least not before the fruit is set, as frosts sometimes cut off the early blossoms, and the later flowers are those that produce the fruit; these, though inferior, are better than none.

VINERIES.

We have so fully described our routine work in previous numbers, that little can be added, at least to the work in the earliest houses. Nothing is now needed except to see that the ventilation is attended to, and the atmosphere not allowed to become too arid. Ventilation of vineries is so important that a few words on this may not be out of place at this time. Where the fruit is colouring it is a mistake to allow the temperature to fall too low. It is all very well in theory to say that the night temperature is low out of doors, and yet Grapes colour well and are not subject to shanking, yet in a house with a low temperature at night they will shank. The temperature ought to be 60° at night when Grapes are colouring, with air on all night; and as the sun acts upon the glass in the morning, the ventilators, front and back, ought to be opened, so that a very high temperature is avoided. In dry hot days sprinkle a little water on the paths and borders.

It is in houses where the fruit is setting that the greatest care is required. Let a keen east wind blow directly upon any of the bunches at this time, and see if the berries will not be rusted; but how to avoid this is the difficulty. The only way is to exercise great care at such a time, and open those ventilators where the wind is not blowing. Air cautiously at all times, not forgetting the oft-repeated injunction to admit air at the highest part of the house at 6 A.M., even if it should be cold. It is better to admit just a little air, and have rather more artificial heat to keep the house up to the required temperature.

GREENHOUSE AND CONSERVATORY.

The Camellias have not quite done flowering; those that have finished have been removed to one of the vineries. It is not always convenient to find a house exactly suitable in all respects for Camellias after they have done flowering. It may be as well to state that now is the time to force them if a succession of flowers is desirable. Those intended for the latest flowers may be allowed to make their growth in the greenhouse. The earliest-flowering plants ought to have made their growth by this time, and the buds to be forming in a cooler house. Our plants are in a late vinery, where they are partially shaded by the Vine leaves. They are well syringed two or three times a-day, and the moist genial atmosphere causes a strong healthy growth. When the buds are well set the plants are removed to a cooler house, and ultimately either to the greenhouse or out of doors. The plants will not bear forcing in the autumn after the buds are formed; if it is attempted they will drop off.

Azaleas are a grand feature in the greenhouse until the end of June. The earliest-flowering varieties are in flower without any forcing except to keep the house close by day and shut-up earlier at night. Of course the plants should be quite free from insect pests at this time. Thrips are destroyed either by fumigating or by dipping the plants, if they are not too large, in a tub of some solution that will kill them without injuring the leaves. There is one advantage in dipping the plants—viz., that if there are any red spider these will also be destroyed, which would not be the case if the house was merely fumigated with tobacco smoke. Small plants of Azaleas should now be potted into pots a size larger. The Azalea is a rapid-growing plant if it has plenty of pot room; but if stinted in this respect it will still remain in good health, but the growths and flowers will be proportionately puny.

All hardwooded plants now claim attention. Where they are grown, as is usually the case, in a house with rapid-growing Pelargoniums and other plants, it is almost impossible to make good specimens of them. They must be placed in a position where the top of the plant is within, say, a foot of the glass, and no other plant ought to come in contact with it. Abundant ventilation is also quite necessary. Any of the later-flowering species that are not yet trained into shape should be done forthwith, as the flower buds are apt to be rubbed off if they are formed before the training is completed.

Stage and fancy Pelargoniums are now throwing up their flower trusses; and one thing we will notice as it is very important to successful culture—viz., Do not overpot. All this class of plants produce the most flowers and these of better quality if the pot is crammed quite full of roots at the time the flower trusses appear. It is marvellous the number of good trusses of flowers that can be produced on a small plant in a 5 or 6-inch pot. Green fly persistently attacks Pelargoniums of this class, and the plants must now be perfectly cleansed of them by fumigating. If they are not clean before the flowers open, it is not possible to destroy them after without injuring the flowers. The action of the smoke causes the petals to fall off in showers.

Roses in pots for late flowering have been attacked by the bud worm and aphis; the latter was destroyed by fumigating, and the other by hand-picking. These matters must be attended to at the moment. We destroyed mildew on its first appearance by puffing sulphur on the leaves.

If cuttings of the perpetual-flowering Carnations have not been put in they ought to be done at once. Ours were struck early and have been potted off. The old plants are now very gay with flower and are highly prized. Some of the recently introduced varieties are a great advance on the old sorts, although a few of the old sorts will still hold their own. The beautiful dwarf-flowering flesh-coloured variety, Miss Jolliffe, is very distinct; it is one of the easiest to propagate, and produces the largest number of flowers.

Mr. Charles Turner of Slough has sent out some really fine and distinct varieties recently. Empress of Germany and King of the Belgians are two of the best of them; Diana, Picturata, Proserpine, Le Grenade, Gloire de Lyon (a fine flake), Celestial, Vulcan, and Avalanche are also distinct.

Pot Fuchsias, Zonal Pelargoniums, and other plants for autumn and succession flowering.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Ellwanger & Barry, Mount Hope Nurseries, Rochester, N.Y.—*Illustrated Catalogue of Ornamental Trees.*

Dicksons & Co., I, Waterloo Place, Edinburgh.—*Descriptive List of Florists' Flowers.*

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BATH.—May 12th, September 1st and 2nd. Mr. B. Pearson, 13, Milsom Street, Sec.

BLACKBURN.—May 17th, 18th, and 19th. Mr. W. Ditchfield, Hon. Sec.

CRYSTAL PALACE COMPANY.—Flower Show, May 29th; Rose Show, June 19th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.

COVENTRY.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.

LEEDS.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.

BURTON-UPON-TRENT.—June 16th. Mr. Wm. Shave, Bond Street, Sec.

JERSEY.—Rosee June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

GLASGOW.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.

FAREHAM.—June 23rd. Mr. H Smith, Sec.

EXETER (Rose Show).—June 25th. Mr. J. N. Gray, Queen Street Chambers, Hon. Sec.

REIGATE (Rose).—June 26th, 1875. Bushby Britten, Esq., Hon. Sec.

WISBEACH.—June 30th. Mr. C. Parker, Hon. Sec.

MAIDSTONE.—(Roses), June 30th, at Viuters Park. H. Benstead, Esq., Hon Sec., Rose Club, Mill Street, Maidstone.

BIRMINGHAM.—July 1st, 2nd, 3rd, and 5th. Mr. Quilter, Aston Park Sec.

SPALDING.—July 1st and 2nd. Mr. G. F. Barrell, Hon. Sec.

SOUTHGATE.—July 3rd. John Miles, Esq , Hon.-Sec., Southgate, N.
DURHAM AND NORTHUMBERLAND.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.
GRANTHAM.—July 7th and 8th. Schedules, &c., from Mr. Lyne, Bookseller.
FROME (Rose).—July 8th. Mr. A. R. Baily, Hon.-Sec.
KILSUY.—July 8th. Sec., Mr. C. E. Bracebridge.
NOTTINGHAM.—Rose Show, &c., July 8th, 9th and 10th. Apply to Alfred Kirk, Municipal Offices, Nottingham.
OXFORD (Roses).—July 9th. Mr. C. R. Ridley, Hon.-Sec.
HEWORTH.—July 14th. Mr. R. H. Feltoe, Heworth, York, Hon.-Sec.
OUNDLE.—July 14th. Mr. Alfred King, Sec.
TONBRIDGE.—July 14th. Mr. W. Blair, Free Press Office, Hon.-Sec.
WIMBLEDON.—July 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Sunnyside, Wimbledon, Hon.-Sec.
DARLINGTON.—July 15th, at Southead. William Hodgson, Sec.
BRECON.—July 22nd. Mr. W. J. Roberts, Sec.
HELENSBURGH, N.B. (Rose Show).—July 23rd and 24th. Mr. W. Uro Waddell, Sec.
CLECKHEATON.—July 24th. Mr. S. H. Williamson, Hon.-Sec.
PRESTON.—July 28th and 29th. Mr. W. Troughton, 4, Church Street, Hon.-Sec.
SOUTHAMPTON.—July 31st and August 2nd. Mr. C. S. Fuidge, 32, York Street, Lower Avenue, Sec.

TO CORRESPONDENTS.

*** **All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.**

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*F. W.*).—Our "Fern Manual" contains a descriptive list of greenhouse Ferns and how to cultivate them. A new edition is now being printed. (*Alliance*).—Our "Garden Manual" contains the information you require. You can have it free by post if you enclose twenty postage stamps with your address.

REPOTTING AZALEAS (*East of Fife*).—The plants, now that they are growing freely, should be repotted in sandy peat, affording good drainage. Water carefully for a time after potting, and keep in a house with a brisk moist heat as that of a vinery at work; sprinkle overhead morning and evening, keeping the plants in heat until the growth is complete and the buds set, when they should be removed to a cooler and more airy house.

CHARACTERISTICS OF SHOW FLOWERS (*J. A.*).—Our "Florists' Flowers" contains many characteristics. You can have it by post if you enclose five postage stamps with your address.

SOUTH-WEST WALL (*Bluebell*).—Any plants or fruit trees you like to plant against it will succeed. We cannot answer particularly so vague a question. We cannot guess what kind of plants or fruits you would prefer.

SEEDLING ANEMONES (*L. L.*).—Your seedling Anemones are all varieties of Anemone hortensis except No. 3, which is a variety of A. coronaria. Some of these varieties of hortensis are very pretty, especially No. 2. The white-flowered one, marked No. 4, is Anemone nemorosa.

LIQUID MANURE FOR ASPARAGUS (*L. I. B.*).—The finest Asparagus we ever grew was watered with house sewage. A trench drawn between each two rows was filled daily. The drainage from the stable one gallon to twenty gallons of water may be used. The period for applying it is now, and as long as cutting continues.

SYCAMORE TREE (*J. S.*).—It can only be the outer bark that is decayed, or the tree would have died. Such being the case you may remove the earth from round the tree, and cover the place where the bark is decayed with a plaster of cow-dung and clay.

GRAPES SPOTTED (*E. Smith.*).—The roots are inactive. If the roots are inside the house, water them copiously with weak liquid manure slightly warmed. If the roots are outside the house, put a heap of hot fermenting dung over them.

CALL DUCKS IN GARDEN (*C. A. J.*).—They will pick up slugs, and do little or no injury to the plants beyond resting on a tuft of some creeper. If there is grass around the water in your garden they will not eat other green leaves.

SOAPSUDS FOR MANURE (*C. Y.*).—They are slightly fertilising, and their benefit arises from the soda and the fatty matter combined with it. If used as you propose, in combination with a manure containing sulphuric acid, the fertilising power would be increased. The acid would combine with the soda, forming sulphate of soda, which is found in most plants, and has been applied beneficially to Potatoes and Peas.

DAHLIAS FOR EXHIBITION (*Eda*).—James Cocker, purple; John Standish, bright red; Herbert Turner, French white, with a soft tinge of lilac; Arbitrator, buff or fawn, suffused with purple, yellow at the base of petal; Mr. Sinclair, rose, tipped purple; Leah, golden yellow; Ovid, puce; Thomas Goodwin, maroon; Alexander Cramond, maroon, shaded with crimson; Flag of Truce, white, occasionally tipped lilac; Duke of Cambridge, shaded orange; William Pringle Laird, lilac. *Fancy:* Dolly Varden, white, striped with purple; Mrs. Saunders, yellow, tipped with white; Remarkable, reddish buff, striped with maroon; Flossie Williams, dark, flaked with purple crimson; Ebor, chocolate, dark maroon striped; Viceroy, rosy lilac, crimson stripes.

SELECT STOVE ORCHIDS (*Idem*).—Cattleya Mossiæ, Dendrobium Bensoniæ, Lælia purpurata, Masdevallia Harryana, Odontoglossum Alexandræ, and Odontoglossum grande. For baskets, Dendrobium Parishii, D. chrysanthum, and Stanhopeas devoniana, insignis, oculata, and tigrina.

LILIUM BROWNI (*H.*).—We can only hazard a conjecture that the Lilium you had as "Bruno," is Browni, also known as L. japonicum. It attains a height of 2 to 3 feet, having four or five large white flowers, richly tinted externally with brownish purple, or it may have been one of the varieties of longiflorum, which are dwarfer.

PRIMULA JAPONICA SOWING (*Villa Garden*).—Sow now and place in a mild hotbed, keeping the soil moist, and the plants, if you are fortunate in having new seed will soon be up, and will flower next spring, but if the seed be not new it is likely germination may be deferred until about this time next year; therefore, if the seedlings do not appear shortly after sowing retain the pot or pan, and keep it moist, by which you may be rewarded in due course with plants. By seed sown so soon as it is ripe we have had seedlings in a week after sowing. Guard against, or keep a good look-out for, slugs, they being very partial to the seedlings.

TRAINING VINES (*F. I.*).—The shoots which are to form the spurs should be 1 foot apart on opposite sides of the rod, so that on each side of the rod they will be 2 feet apart, and the cane or rod between them should, of course, be clear of shoots, rubbing off any eyes that may appear upon those spaces. The shoots should be stopped one or two joints beyond the bunch, better the first if space be limited, as they will break again, and must be pinched to one joint—*i.e.*, each succeeding growth, or if you have ample space stop the shoots two leaves beyond the bunch. All the laterals should be removed but the two lowest, and those stopped at the first leaf. Stop the leading cane in the ground vinery 1 foot from the end, its succeeding growth to one joint, and the laterals upon it to one joint, and the succeeding growth stop at the first leaf. There is no necessity to add to the length this year, and growths made outdoors would be of no practical value to the Vine in the ground vinery.

WEEDS ON LAWN (*P. T. B.*).—Lawn sand is highly spoken of, but we have not used it. Write to the advertiser and ask for particulars. We should not think the dressing with soil as you propose would be advisable until the lawn sand had been applied, and had had time to exert its influence upon the weeds, and then you may dress with the rich compost, and sow with grass seeds as you propose; but do not sow the seeds first and then dress with the compost, which would be to bury the seeds too deeply. They should not be more than lightly raked, or better well rolled-in.

SHRUBBERY BARE AT BOTTOM (*Idem*).—The shrubs are bare at the bottom from growing too thickly. Both Laurels and Laurustinus are good growers, and bear cutting well. They will start from near the base and give you the bottom growth required, providing that light be afforded. We should not dig amongst these shrubs, but as the ground is liable to be baked in summer, the surface of the soil may be loosened with a fork, just pointing it over, and if you could give the shrubs a light top-dressing of rich soil they would amply repay you in growth. What they require to give you closer growth is pruning more closely, which may be done now. The fowls do the shrubs no harm, but are more likely to do good in devouring numberless insect pests, which not unfrequently commit great havoc amongst shrubs.

MARANTA BARAQUINI CULTURE (*A Subscriber*).—Maurantas to do well require a rather warmer and moister atmosphere than is afforded to a majority of stove plants. The temperature at this season should be 70° to 75° by day from fire heat, and 85° to 90° with sun heat, and at night 65° to 70°, affording shade from bright sun, and keeping up a regularly humid atmosphere. Lightly sprinkle the plants overhead morning and evening, and keep the paths and every available surface wet. Use water of the same temperature as the house. The appearances you state as those of your plant are such as are usually a result of the growths being made in a low temperature. Moderate ventilation only is required, and this without causing sudden cooling or drying of the atmosphere. The present is a good time to repot the plant. Free watering is necessary.

CLIMBERS FOR GREENHOUSE WALL (*H. W.*).—If shaded by Vines on the roof, plant Camellias. If not shaded, Mandevilla suaveolens and Lapageria rosea.

DESTROYING WOODLICE (*J. H.*).—They are very wary poison-takers, and are not easily vanquished by other means. A ready means of destruction is a toad or two in each house, which feed upon these and other insect food. By having one or two in each house we have found these animals keep the wood lice in reasonable bounds. Another plan is to place some pieces of boiled potatoes along the sides of the walls, and other places where they congregate and hide, covering the potatoes with a little hay, and in the morning following a two-nights enticing, pour upon the hay boiling water, which, of course, destroys all it comes into contact with. Places should be chosen for the enticing and scalding process where the pouring of boiling water will not do any harm to plants or their roots. We have also found great service from mixing a tenth part of arsenic with finely ground oatmeal, moistened with a little olive oil and thoroughly mixed, forming a crumbling paste, and laying this on pieces of slate in their haunts, taking care to keep it from domestic animals.

CALCEOLARIAS DYING (*Idem*).—It arises from a decay of the neck or collar of the plant, and is mostly a consequence of the plant in a young state having been pot-bound, and at potting being placed deep in the soil, so that the neck is covered. Watering upon the stem is also a prolific source of the evil. Calceolarias delight in a cool and moist atmosphere. Soil also has great influence, and we have found that soil of a peaty nature is more inimical to the plants than that of a loamy character. The whole subject is involved in mystery as to the cause; the decay is common, not only to Calceolarias, but to Cinerarias and Humeas.

INSECTS IN GREENHOUSE (*D. M. M.*).—The beetles you have sent are the common brown weevil, Otiorhynchus sulcatus, which is far too well known as most destructive to pot plants (gnawing the roots just below the crown), also to buds of Vines, &c. We fear two or three females must have found their way into your house and there laid their eggs; but surely their white fleshy grubs must have been at work for months or weeks without you having noticed them. In their present state there is no better plan than that which you suggest of hunting for them with a light after dark, and laying a sheet under the plants, on which they fall as if dead.—I. O. W.

ANTS IN HOTBEDS (*Mrs. J. Ll. M.*).—The best means of destroying them is to place small pieces of beetle poison about the size of a pea on a piece of slate in their runs, taking care that no domestic animal partakes of it. Another good plan is to have two pieces of sponge, dry and clean, and on two sides smear them with honey; place those two sides together, and put the pieces in the haunts of the ants, which will pass into the sponge, and may be immersed in boiling water. It answers nearly as well to dredge the sponge with powdered loaf sugar; the sponges having been washed clean and dried may be used again and again. Ants are also fond of olive oil; this, placed about 1½ inch deep in jam pots put in their runs will take them in great numbers, it may be left until rancid, then the pots should be thoroughly cleaned and renewed with oil. The best salad oil should be used.

NAMES OF PLANTS (*E. S. H.*).—It is the double white Wood Anemone, Anemone nemorosa flore-pleno. It is sometimes called the Double White Hepatica. (*J. A. O.*).—The white Narcissus is N. pseudo-Narcissus var. Moschatus; the yellow one, Double Campernelle. The Scilla is amœna. The others Primula ciliata purpurea and Euphorbia hibernica. (*H. W.*).—The Jonquil, Narcissus Jonquilla. It is a native of Spain, and described as long since as the reign of Elizabeth by Parkinson as the "Junquilla," and in every European language it has a similar name allusive to its rush-like leaves, from Juncus, the Latin for a Rush. (*Subscriber's Daughter*).—Claytonia perfoliata, and the Wood-rush, Luzula campestris.

POULTRY, BEE, AND PIGEON CHRONICLE.

COULEUR DE ROSE.

WE suppose at times the hues of *couleur de rose* are wont to bathe everyone and everything in its attractive tints. This descriptive epithet, imported from a foreign country, is untranslatable in English. If we hunt the term out in a French dictionary we find it means something bright and joyous. It is all very nice in its own country, where it is used in a much more delicate way than it is here, for in our language it generally comes to mean something bathed in bright and delusive colours, and so may be termed in our significant word—humbug. Now-a-days we find this rose tint laid on many things in a delicate manner, and so making them appear under false colours. Many, too, put on rose-tinted spectacles, as it were, and behold things looking fair and lovely, but when looking at them with the ordinary eyes of life are disappointed and find out what reality is.

In the poultry world, too, many look on *couleur-de-rose*-bathed scenes, and they themselves frequently scatter the tinted drops on their own property. Many of the poultry people dip their advertisements in this flattering liquid and make them "fair and false, glittering and delusive;" but the rose-coloured garb does them no good, while it mortifies and often hurts the feelings of others. We will take one or two *couleur-de-rose*-tinted cases and see what we have dished up for us in this charming colour. Let us imagine Mr. Paint-it-bright is speaking. "What! My dear Plain-colour do you mean to say that is the best Brahma cockerel you have? I am surprised! Why, I should beat you all to fits if I exhibited. You should see mine—such combs, such tails, and such leg-feather! Oh, what a pity it is you live so far off and can't come and see my stock, for I could put you up to a wrinkle how to get good colour on the thighs and breasts. But take my advice, my boy, and get something better in future." Whereupon Plain-colour is filled with jealous ideas of the most burning character, for he has done his best to get the finest cockerels extant; and though he would give his hand almost to see and possess one of Paint-it-bright's marvellous birds, still he knows they are to him almost as inaccessible as the Arctic Regions.

But something quite unexpectedly turns up and Plain-colour has to go down to Roseshire, and when his business is over straightway he rushes off to see Paint-it-bright's wonders. The hideous reality breaks on him, and he finds *couleur de rose* has indeed been lavished over the description of the birds, for they have ugly coarse combs, brown wings, and thighs mottled to a frightful extent. Still, though he has been so duped he omits to tell his experience to his friend Mrs. Wantcups. She, poor lady, is in search for a sitting of eggs of a very popular and handsome breed called Black Feather-legs; so she turns to our poultry Journal and cons the advertisements. "Victory!" she cries; "here are eggs to sell from some splendid Black Feather-legs. They have only been shown a very few times and they won all kinds of things, beating all kinds of people, who have hitherto carried all before them till this grand yard burst upon the fancy." Mrs. Wantcups straightway sends off her P.O.O., and the eggs come. Poor lady! the advertisement had truly been tinted. The birds had been bred by someone else, and handed over to the then owner in a state of exquisite condition, which had been the cause of the winnings in question, and at the very few shows where they had since won, the great guns which were described as having been so ignominiously beaten had been represented there with only their third strings, their first and second being away at other places winning cups and prizes of themselves much more valuable, and likely to bring much greater glory to the exhibitor. Again, had she looked she could have seen, perhaps, that the rose tints had been laid on coarsely and unevenly, not even thick enough, perhaps, to hide an ugly mixture of pronouns, which is sometimes observable in such painted advertisements. Poor Mrs. Wantcups! she will know in future what *couleur de rose* means.

Other employers of this bright colour there are, wholesale dealers, who go about brightening up everything—poultry shows and poultry committees, poultry managers and poultry secretaries. They go to exhibitions, and they attend sales; they brighten-up, as it were, the plumage of their birds, and distil fair drops of *couleur de rose* on the combs of their fowls; they write their letters with rose-coloured ink; their very pens give rose-coloured accounts of how their Bantam cock, now for sale, is the best out; or how they would never sell that Tumbler cock if the hen had not died.

Couleur de rose, too, we find mixed up in new kinds of goods, and little sparkling stars of it on new-fashioned coops and wire enclosures. Certainly the poultry world often is blessed with a rosy shower. And then there are some who go to exhibitions to pick-up news and retail it out again; who make friends with the committee, or get introduced to the secretary through some other rose painter. These artists especially love shows where the committee in a time of success, and as a reward after hard work for months in organising their show, go in for a bottle or two of clicquot in some cosy office, and offer, in the exuberance of their joy at seeing their room full of visitors, a glass of the thrilling beverage to our friends; and they then drink of the sparkling vintages out of rose-tinted goblets, and go home, on their journey in imagination dipping little slices of bread into the cups of wine now become flat and insipid, trying to reanimate their brilliancy with bright spluttering bubbles, and commit to their note books all that they saw fair and beautiful, and forget the thorns that grew beneath the rose's petals.

Again, some publish little books on poultry, and tell of profits that set the readers' brains whirling, and make them hasten to Stevens and embark on the poultry mania. All humbug. They can only tell the old story; but here they have dished it up tastefully with a rose-coloured sauce, and the tints have been so plentifully spread, that the wretched maniac who took the poultry farm, thinking his fortune was made, curses the day he ever read the delusive pamphlet.

We have said enough, shown instances enough, and we can readily see that those to be our friends in this the poultry fancy, as in other scenes, must be those who present themselves and their goods to the world through no rosy-tinted windows, but honestly and truthfully through panes of plain glass, where *couleur de rose* exists not to humbug outsiders, where the fancy in walking through the world may see truthfully what the man and his goods are.—W.

A PROPOSED ESSEX AGRICULTURAL SOCIETY'S POULTRY SHOW.

I HAVE just received the schedule of a poultry show to be held at Brentwood, in connection with the Essex Agricultural Society. The latter fact, to which attention is invited, is a somewhat ominous one. Last July a show was held at Stratford under the same auspices; I was fortunate enough to be a prize-winner, but did not succeed in obtaining my prize money. For months I wasted letters and post cards on Mr. Cornerford, the Secretary, who never deigned to answer me till I sent him a somewhat forcible reminder, upon which he coolly wrote back that "he regretted he could not comply with my request, as his books had long been closed." I therefore inform the public of the way in which the Show in connection with the Essex Agricultural Society was managed last year. How far the said Society is legally responsible for Mr. Cornerford I do not pretend to gather from the singular ambiguity of the schedule's heading, but it is sufficiently discredited by his repudiation of exhibitors' just claims. I observe that there is this year a new Committee, among them I see the name of a clergyman which will command general respect, but I have yet to learn that a society by changing its officers obtains liquidation of its debts.—O. E. CRESSWELL.

EGGS.

I NOTICE a contribution on page 283 signed "W." under the above heading, and although I coincide in many of the statements there contained, I believe the following remarks will show a different side of the picture.

I have been a large breeder of poultry during 1874, having reared over 1300 fowls, many being sold at over a sovereign each, and as much in one case as £8 10*s.*, and now have upwards of two hundred head pure and crossed for certain purposes; but as "W." says, wishing to make my poultry-yards more attractive, early this year I ordered sittings of eggs from various advertisers. Each sitting was carried by myself from the station to prevent any accident in shaking, and my results (after an expense of over £13 in eggs, besides buying broody hens for hatching from almost all parts of England at 4*s.* 6*d.* and 5*s.* each, and carriage in addition) are as follows, without mentioning names. Houdan eggs from Stonehouse, Gloucester: one contained a chicken, but could not survive the necessity of breaking away from the shell after twenty-two days sitting. White Cochins from Melksham; Crêve-Cœurs from Chatteris, Cambridgeshire; Golden-spangled Hamburgh eggs from Bourne, Lincolnshire; La Flèche, Houdan, Crêve-Cœurs, and Silver-spangled Hamburghs from Banbury; Silver-spangled Polands from Wivelscombe; Black Spanish from Penge; and out of the last-named nine lots not one single egg contained a chick or even sign of life.

Each egg which I have reserved for inspection, after making a small hole in the side, being perfectly sweet and the yolks perfect, and not broken or mixed up. My opinion goes with "W." that if an egg has been fertilised, and after forty-eight hours' sitting signs of life are evident upon breaking the egg; and if through too long exposure by hen or other cause, the life being destroyed, the egg becomes putrid, hence the appellation "addled;" whereas if, although cocks do run with hens, the eggs are not fertilised, after twenty-one days' hard sitting they are almost as sweet, as far as the yolk goes, as when they were laid. I can guarantee that each hen was sat in a separate place, with the board at front of the nest removed each morning, and never allowed off more than ten minutes, and food, water, and ashes ready for immediate use. To this matter of hatching I give my own personal attention for fear of neglect.

Now, on the other hand, I had a sitting of eggs from Instone, Devonshire, by error first sent to London, afterwards here, and out of thirteen eggs I have twelve chickens. Out of twenty-six eggs sent direct from the United States of America, travelling upwards of four hundred miles in the cars, then across the Atlantic, passing through the Custom House, and then through two railway offices in England, twenty-four hatched. I had also a sitting of Partridge Cochins from Woburn, Bedfordshire, and five hatched; and I almost think this sufficient proof that if eggs are fertile and fresh that carriage, if properly packed, has little to do with failure in hatching.

Now, "W." and the managers of other poultry papers recommend each egg to be wrapped in paper, then separately in a wisp of hay. I contend the less the eggs are handled the better; and to first roll them in paper, then roll them in hay, afterwards laying them down, then picking-up and packing, all tend to shake the egg, and when packed it seems to me that each egg then has a separate tendency to be shaken, being, as it were, on a spring mattress by itself; whereas if short-chopped hay and straw mixed, say three-quarters of an inch long, be used, and the eggs as laid be packed in that no shaking will hurt them if sufficient to fill the package is used, as one straw remaining between two eggs will prevent the friction, and this chopped hay and straw the more shaken the greater the tendency to form a solid mass. Bran, sawdust, sand, and other such articles, all go into smaller compass with very little shaking, and if a package is full to excess at starting on a journey, it is more than probable it occupies a sixth or eighth less space on arrival at its destination, and the eggs most likely shell against shell, and in most cases broken. This plan of packing was adopted in above satisfactory cases, and is now by me in sending eggs; and although I have sent them to all parts of England this spring, I have most favourable reports of the hatchings.

I for one do not hold with advertisers offering second sittings at half price, as it appears on the face too great a temptation to ill-disposed persons to send bad or tampered eggs the first time to insure a second order. I believe it eventually will come to legitimate breeders warranting the greater portion of eggs fertile, and in future I shall purchase from no one who will not give a guarantee I dare to give myself.

Most poultry fanciers know how much more certain eggs are to hatch in May and after months, and half the fault I believe—as I cannot think, bad as my luck in bought eggs this spring has been, that they have been tampered with—lies in the fact that during the cold months of spring the fowls are not fed with warmth-producing and sufficiently stimulating food. I have now alive and well, hatched from my own fowls' eggs, nearly 150 chickens and ducklings, and thirty-two hens sitting to hatch within the next ten days, and have found but three unfertile eggs. I do not speak of the early Ducks, as drakes are very liable to object, perhaps, to the best laying Duck, and my hens have laid throughout the winter an extraordinary quantity of eggs, and out of the large number I keep have this spring been able to keep them from becoming broody until quite recently.—Hampton-in-Arden.

RUSSIAN TRUMPETERS.

As Mr. Ure's account of the easiness with which these birds breed and rear young may cause some disappointment in those who intend to keep prize birds in England, I will quote the letter of a gentleman in Ireland who keeps these Trumpeters, and has taken prizes even when Mr. Fulton has exhibited.

I have before stated that a great Trumpeter fancier cannot get two imported prize birds to breed successfully. Now for the details of the Irish fancier: "Two-thirds, if not three-fourths, of the young (of imported birds) have not been reared, or have died in their first moult." Of the doings of a pair of thoroughbred birds this season the gentleman writes, "They have hatched two sets of eggs, but all four birds have died at about five days old, although changed under undeniably good feeders. I do not know why they died, as they hatched out strong without any assistance, and they did not die from any fault of the feeders. The first year I had three sets of young; all died in the same unaccountable way, not from cold, as the old birds had not left off sitting on them. The old foreign birds are excellent feeders, as they invariably rear the feeders' young birds if allowed, although their own young die under the feeders." These foreign birds "are evidently very much inbred, and in consequence some individuals are barren.

"I have now two foreign birds of my own breeding, both sterile; the hen only laid one small egg last season, and has never laid another. They have both been tried with various half-bred hens and cocks without success, but their brothers and sisters are now breeding freely." Again, "I have not as yet reared a thoroughbred bird this season." Again, "When once reared and over the first moult they seem healthy enough." It would seem, then, that there is a special difficulty in inducing these birds to breed successfully. Probably Scotland does best for them, being nearer home.

I would thus sum-up the result of my inquiries: Foreign Trumpeters breed in England very badly, many hens will not lay, a very large proportion of the young die in the nest, and a large proportion of those which survive the nest die at their first moult.—Wiltshire Rector.

On reading "Wiltshire Rector's" remarks on Russian Trumpeters I felt sure he had been misinformed. This bird is not the only foreign Pigeon that used to be thought useless for breeding purposes in Britain, and I think I can give the reason. I have had more than once Fantails from India, useless but for show, splendid birds of the kind, and on inquiry where they were obtained I found they had been bought in the market of Calcutta.

Now the public market is like the auction room in this respect, that what you buy you take with all faults. In countries where fine birds are bred it is only the worn-out, barren, or otherwise useless birds that are sent for sale to the public market (occasionally a sound and good bird may be bought there), and this I think accounts for the fact that so many birds brought to this country by sailors are found to be non-breeders. Those birds, however, received from regular importers, though the price may be a little higher, as a rule breed well. Certainly even importers may have a useless bird thrown on their hands, but their purchases may be depended upon, as they buy not in the public market but from breeders.

The Trumpeter has always been a favourite of mine. His characteristics are so prominent; and one of them, his note, is most pleasing to me. Recording notes on the Trumpeters brings to my recollection a bird I used to have many years ago, but which I have not seen since—viz., the Laugher. The birds I had came from Jerusalem; they were brought by a sailor, and did not breed, but were grand feeders of Ponters. The Laugher is one of the old Toys, about the size of the Russian Trumpeter. The flight feathers were very long, no crest or rose, legs and feet free from feathers; and those I had, three in number, were mottled not unlike the Almond Tumbler, but with a greyish-white ground. When cooing to his mate the male bird would break into what resembled a very hearty laugh, and repeat this laugh three or four times.

The resemblance to the human laugh was so striking as to be utterly ludicrous, and caused myself and friends who heard them to join in chorus. I shall be glad to learn that Mr. Baily succeeds in securing some of this old and remarkable Toy Pigeon. I should like a pair, breeders if possible.—James Huie.

CANARIES.

When writing my notes on these birds in a previous issue of our Journal I unintentionally omitted to name one variety which I always had a great fancy for, and which I think is well worth the attention of Canary breeders, quite as much so as the Lizard, being a marked bird of handsome form—that is, the London Fancy Canary.

There is a fineness about this variety possessed by none of those I named. Young birds when displaying their black flights and tail have quite an exotic appearance, and their colours and form present the results of careful and high breeding. Like the Belgian it must have taken many years, perhaps many generations, to bring them to the perfection at which they now are.

I trust the breeders of the London Fancy will not stoop to artificial colouring in any form, but continue to produce birds intense in colour (as I have seen them) by means of careful selection.—James Huie.

Poultry Prizes at the Bath and West of England Show.—We have received the prize schedule of the Bath and West of England Society's Show, to be held at Croydon on the 1st of June and three following days. As heretofore the list is a liberal one, fifty classes being devoted to poultry, with prizes of £2 and £1 in each class, besides fifteen silver cups valued at £5 each, the winners of these cups receiving them in lieu of first prizes. There are sixteen classes for Pigeons, the premiums in each instance being £1 and 10s. The entries closed on the 4th.

The great care and attention paid to the poultry during so many years past cannot but insure the confidence of all competitors, and the rigid manner in which the regulation is carried out, prohibiting any "exhibitor or servant" having access to the birds until they have been judged, will meet with general approval.

CRESTED NORWICH CANARIES.

As proof of the high favour in which Crested Norwich birds are held, no less than 132 specimens were exhibited in the five classes at the last Crystal Palace Bird Show. Of late years especially, quality of breed and colour have been studied by fanciers who have much improved the Crested breed of Canaries. This improvement has been effected by crossing Norwich birds with the old crested strain, most of which formerly were of dark plumage and strong in constitution. From this cross has originated the title or appellation of "Crested Norwich."

In years past Crested Canaries were more familiarly understood by the names of "cappled" or "coppled-crowns," "tassel-headed," or "toppins," and even at the present period in out-of-the way districts of the midland and northern counties, where the intelligence of the more educated fanciers of the bird-world has not reached, may be occasionally heard some such designations applied to Canaries possessing this peculiar ruffled adornment of head feathers. And it would be a difficult matter to uproot fixed notions from the minds of some, particularly those in the rural districts, who will stoutly contend the point with you that a Yellowhammer is nothing but a Goldfinch.

I have frequently been amused whilst listening to contentions over the terms "caps," "crests," "toppins," or "tassels," but the arguments have generally ended without any decisive results. Some have wisely contended that the term "cap" applies to a bird with a covering of feathers over the entire crown otherwise than is the case with a crested bird, which is often somewhat deficient of feathers in the centre of the crown. Other fanciers have placed their faith in the word "toppin," because the feathers are elevated above the crown of the head. I prefer either designation in preference to the word "tassel," for the reason that this particular ornamental and decorative bunch may be worn or suspended from other parts than the head. In my opinion the word "crest," which signifies a plume, has a greater claim than all others.

Crested Norwich birds vary in general formation of crests from the massive made birds styled "Manchester Coppys," for instead of the crest in the Norwich graduating into smooth feathers from over the eyelids to the back part of the head as in the Coppy, the crest is mostly continued around the head, the feathers behind inclining upwards. This in most instances produces baldness, which is an eyesore.

Although breed and colour have been imported, the crests vary in form and appearance. Some crests, although thickly feathered, are short and stunted, and resemble a flower only half blown, appearing as though the feathers had been cropped-off over the beak. Such do not find much favour. A skeleton formation of crest, which is known by the large bald centre-piece of the crown with a thin line of feathers over the beak and eyes, is also objectionable, and will never make headway against a flowing, full-feathered, high-cultivated crest, which appears as though a brush and comb and smoothing-iron had been at work. I like to see the feathers fall heavily, regularly, and even over the beak and eyes, diverging from the centre of the crown which is termed the "pea."

In a spare-feathered crest one great fault is the mere outline or apology for a crest, with the "pea" nearly half the size of a threepenny-piece. Some crests partake of a more pointed or narrow form over the bill, but become gradually wider towards the back part of the skull, where they terminate somewhat square, and take an upward curl of feathers at the extreme sides. I consider such shaped crests defective, for the very reason that the greatest weight of the crest should be over the beak and eyes, with the crest somewhat compressed in appearance and fully developed. Dark crests show to greater advantage especially in full-sized crested birds, with an inclination for the dark feathers to be continued so as to form a short hood. They are more showy than button-crested birds, and are preferable to grizzled or clear crests, the latter especially showing to the least advantage. Still I have seen some such crests tolerably good. To increase or encourage size of crest it is advisable occasionally to breed with two buff birds, one crested and the other plain-headed of the crested strain.

There are two essential matters to study in the breeding of good Norwich Crested birds. In size they should not approach the Coppy breed; if so they run the chance of being disqualified when exhibited. Good healthy bold-looking birds should be selected for breeding purposes, and in matching avoid putting together a pair strong in colour, and each having crests.

The number of classes set apart in the schedules of the most important shows varies. Sometimes there are only a couple of classes, whilst at other times as many as five or six classes are set apart. The foremost or principal classes are those for even or beat-marked crested birds (yellow or buff), possessing dark crests and with an even number of dark smaller flight feathers, the remaining portion of the bird being clear, unless there be a dark feather on each side of the tail. Next to the even-marked birds stand those entirely clear excepting the crest. Crest is the chief point of perfection; condition, plumage, and other points of consideration being studied in judging as in other kinds of Norwich birds.

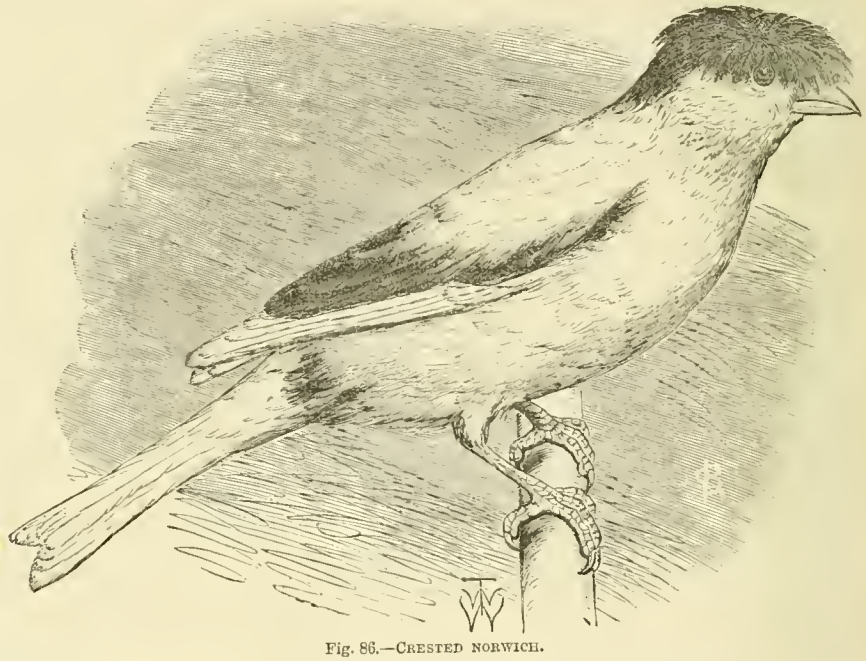

Fig. 86.—Crested Norwich.

The engraving we publish represents one of the finest specimens of a Crested Norwich it has been our pleasure to see. The bird is possessed of all the essential qualifications for the high honour it gained for its owner—Mr. Woodward of Derby, who exhibited it at the last Crystal Palace Show, and added a first prize to several others previously won. The bird is a hen, eighteen months old, and was exhibited in "Class 10, Evenly-marked Crested Buff Norwich." Thirty other specimens were shown in the same class.—Geo. J. Barnesby.

TRADE IN FOREIGN GAME AND POULTRY.

This has rapidly grown up within the past few years, and experience has almost solved that problem of food preservation wherein science is yet at fault. For instance, the poulterers who are consignees of birds from America receive great numbers of casks in which are now packed, with perfect safety, vast quantities of game that would inevitably have been spoiled if the same thing had been attempted with imperfect knowledge a few years ago.

The Prairie bird, a species of Capercailzie, which has the feathers down the legs, and which gastronomera have declared has the bitter back-bone so highly esteemed in the true Grouse, comes across the Atlantic with little or no injury from the voyage, though, it must be granted, with some little sacrifice of tenderness, by the method of preparation for packing. This

is, to take the bird fresh and to freeze it to the very middle. Thousands upon thousands are passed into freezing houses artfully constructed for the purpose. When quite stiff and hard they are taken out, wrapped in coarse paper like bottles of champagne, and packed carefully in barrels. The paper plays a very important part in the business. In the first place it is a non-conductor, and it therefore assists in the isolation of each bird, so that when the barrel is opened at the end of a fortnight's voyage the contents have positively not begun to thaw. Then, again, the wrappage keeps the feathers smooth; and the birds being more sightly find a better sale. It is said, indeed, that a shilling a brace, or more, is the difference between Prairie fowl which have been wrapped in paper and those which have not. As for the freezing process itself, something of the same kind has been an old practice in Russia and Canada for home purposes, and the Russians know well that the best way of thawing the frozen birds is to begin by putting them in cold water.

A more delicate bird than the Prairie fowl—namely, the Virginian Quail, is brought to English markets in the same manner as that we have described in the case of the Prairie hen, which, by the-by, is sometimes called—with sad ignorance of natural history—the Canadian Pheasant. Epicures may sneer at both these dainties; but they would not sneer at either were they to taste them skilfully prepared in New York or Montreal. Even here, after the freezing process, the packing, and the sea voyage, a housewife with a quick eye for the signs that make or mar a bird for cooking will be able to pick out a plump young brace from a row of these Prairie hens in front of a poulterer's shop. Up to the present time the outlay has been £93,000; and we believe that the round sum of £150,000 will be about the ultimate cost of this well-planned poultry market. — (*Irish Farmers' Gazette.*)

FEEDING TROUGH.

This is the best and handiest instrument for feeding bees that we have ever seen. It is made of tin, and costs 4*d*. It can be made of any required length, and narrow enough to enter hives of any kind. By filling this trough on the flightboard of a hive and pushing it into the hive the bees can be easily fed. The trough can be pushed 2 or 3 inches beyond the doorway, and

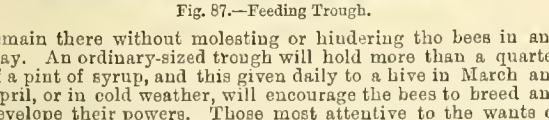

Fig. 87.—Feeding Trough.

remain there without molesting or hindering the bees in any way. An ordinary-sized trough will hold more than a quarter of a pint of syrup, and this given daily to a hive in March and April, or in cold weather, will encourage the bees to breed and develope their powers. Those most attentive to the wants of their bees in cold weather will generally have the largest harvests of honey at the end of the season.—A. Pettigrew.

LIGURIANS.

I had no wish to continue any controversy on this subject, but as Mr. Pettigrew challenges me I feel bound to reply. In the first place I never doubted the wisdom of settling the matter—*i.e.*, the superiority of Ligurians, for I consider the matter long since settled, and it seems to me on a par to trying the convict Orton over again. Your valued correspondent "B. & W." has said in your columns, "The breeding powers of the queens in my possession, particularly the hybrids, have been greatly in excess of anything I had ever experience of before. . . . I have found this fecundity quite a nuisance, as they have multiplied to such an extent in hives as to have occasioned an excess of swarming." I will quote no other opinions, but by reading any of the American, German, or English bee journals any apiarian will find numberless confirmations; so taking my stand on "B. & W.'s" opinion I will say although I never said it before, "If the Ligurians are better breeders, it follows they are better workers."

Instances are not uncommon of queens producing such a great quantity of brood that the hive has no space left available for honey storage unless a super be supplied, and then again if the super be removed at the close of the honey season the stock may die from famine unless fed with judgment. Experience and care will guard against both these contingencies, although perhaps the race would be blamed by the ignorant for the misfortune.

In the poultry world we do not find a breeder of Brahmas writing down Cochins, or the Dorking fancier maintaining a controversy to prove there is nothing so good as his particular favourites. Each have points of excellence, and so have the varieties of bees, so I say *Chaçun à son goût*.

If any of your readers wishes the trial made, why not make it himself? A fancy price need not be paid for queens. They may be imported from Italy in May and June at 10*s*. each, and the old queen of the swarm will be worth half the money to return to her hive, where she will recommence breeding without delay. I am not a bee-dealer (although, of course, I like to make money of my surplus swarms), but I will undertake to import any number of queens required at the above price for purposes of Mr. Pettigrew's wished-for trial.—John Hunter, *Eaton Rise, Ealing.*

SWARMING AND SUPERING.

Both wind and weather at present are favourable for bees, and favourable, too, for fruit-setting in the small orchards in this part of the country. The pear trees are now white with a galaxy of blossoms, and the bees are busy at work on them. Apple and sycamore trees are abundantly covered with flower buds, which are fast expanding. If the present fine weather continue for two or three weeks the probability is great that there will be this autumn a very heavy crop of all kinds of hardy fruit. And who can tell how much the country is indebted to bees for an abundant harvest of fruit? They gather great stores of honey and pollen from gooseberry and currant bushes, plums and cherries, pears and apples, and in doing this they help to a great extent to fertilise and set the blossoms. Such weather makes apiarians think of swarming, supering, heavy hives, great results, the Crystal Palace Exhibition, and the distinctive honour of being successful competitors there. We hope apiarians of all creeds and classes will have a favourable season for honey-gathering, and derive great encouragement and confidence from their own practice and success, as well as pleasure and stimulus from the apiarian *fêtes* that are promised us next autumn. Now let us have a few commonplaces touching general management.

Swarming.—By instinct and a law of their nature bees multiply, swarm, and thus form independent colonies and communities. Swarming is one of the most interesting features of bee history. Even the exploit of hiving his first swarm successfully causes a glow of pleasure to a beginner. If the present fine weather continue there will be many swarms in May, notwithstanding the cold spring. Many hives have their combs covered with bees, and comb-building has commenced in hives not full of combs. A hive filled with combs, and these combs covered with bees, is within three weeks of swarming in ordinary seasons.

Every bee-keeper may examine his hives easily by gently and slowly turning them up to see how much comb is covered. My bees are so accustomed to exposure in this way at this season of the year that they do not seem to be disturbed by being so turned up. Many visitors marvel at the quietness of the bees, as well as the quiet way they are handled. By putting a finger in the mouth of the hive, and raising the front of the hive high enough to have a peep inside, any bee-master may know, to a certain extent, how his bees are doing. All this may be done without smoke or the use of fustian rags. By using smoke from such rags a more thorough examination may be made. As soon as the bees can and do cover all the combs of a hive, eggs are set in the combs from side to side. In three weeks all this brood will be hatched (and more set as it is hatched), filling the hive full enough for swarming. Swarming is hastened, too, by the storing of honey in the combs. The accumulation of honey in the upper and outside regions of a hive compresses the bees in the lower regions, &c., nearer the door, and often sends them outside for room and air. As bees approach the swarming point the heat and noise of their hive become very great in honey weather.

Those who manage their bees on the swarming system should have the hives ready for their swarms. The largest sizes of hives should be peopled by the largest and earliest swarms. We are frequently asked if swarms from small old-fashioned hives will fill 16-inch and 18-inch hives the first season. Such hives may be filled by the first swarms from small hives. If the weather be unfavourable after the bees are hived, a few pounds of sugar will help the bees very much, by enabling them to build combs for the eggs, which are so abundantly produced by their queens. We have given an order to our hive-maker to send ten hives 18 inches wide and 16 inches deep, and ten 16 inches wide and deep. These will be peopled by early swarms, and smaller hives by later swarms. First swarms in May, even from small hives, will, in seasons ordinarily favourable for honey-gathering, fill large hives.

Many young apiarians, anxious to have their bees in large hives, ask if they should put two or three swarms together in one large hive. It is not necessary to unite first swarms, and it is not good policy to do so. Sixteen-inch hives may be easily filled by small first swarms hived separately, and these will make excellent stocks. In good seasons and localities such swarms will fill 18-inch hives. The second swarms and turn-outs of small hives may be united with advantage, and put into larger hives.

Supering, on the non-swarming system of management, generally begins about the first week in May. Indeed, it should be

resorted to shortly after the bees of full hives cover their combs. Supering, before swarming, is somewhat unnatural and artificial, and in attempting it early in the season it is well to remember the words of the Scottish poet:—

"The best laid schemes of mice and men
Gang aft agee."

But still swarming is often prevented by the use of supers of considerable size. If bees readily enter and commence to work in large supers, they frequently fill them, appearing to abandon the idea of swarming till this is done. In large supers there is room for the bees, which multiply so fast at this season of the year.

"If bees swarm when their supers are half filled what should be done?" It is difficult to answer this question. If the swarm were cast back on the old hive it would probably swarm again either the next day or the first opportunity. If the bees were thrown back without their queen they would not swarm again till the young queens were hatched. Piping and swarming may take place after the birth of young queens, but by throwing back a swarm with an unfertilised queen on the front of the mother hive, swarming would be prevented for some weeks—a month at least. To pursue such a course is neither wise nor profitable; it is here mentioned for the sake of those who may wish to appear in good form as competitors at our honey shows. If our bees were to swarm before their supers were filled we should hive them and remove the supers. Such supers could be placed on other hives, or even on the hives of the swarms as soon as they were filled with combs. If the honeycomb in supers be simply for home use, and not for exhibition, it will be unnecessary to place half-filled supers on other hives.

In supering, the bee-master's aim should be to give his bees room enough in his supers to hold all the additions to the population, and aid them to work heartily in filling them. By using plenty of guide comb—chiefly virgin drone comb—we have seldom found any difficulty in this work. It is very desirable to induce the bees to build combs in supers from their tops downwards. By placing a sheet of paper (with a hole cut to correspond with the hole in the crown of the hive) between the hive and super, the bees do not attach the combs to the hive or even to the paper, thus making the removal of the super a very easy matter. For wood and straw supers, as well as for glass supers, we use, and advise others to use, ladders of wood from the crowns of hives to the tops of supers.

In these days of progress and exhibitions we anticipate some changes in our schedules of prizes. The clamour at present is to bring this and that kind of hive into notice. The common sense and growing intelligence of apiarians will settle this clamour. Swarms of supers will cover our exhibition tables for a season or two, and be much admired, as they ought to be. By-and-by I anticipate that great results in honey and honeycomb, like Mr. Hunter's big bunches of grapes, will carry the day; and for dexterity and ornamental work we shall probably have prizes offered for designs and pictures in honeycomb. Some eighteen months ago the readers of this Journal were told that it was thought possible to cause bees to write "God save the Queen" with honeycomb in a super. If this season be favourable for honey-gathering we shall try to have this inscription in comb over the Manchester Exhibition of Honey next autumn.—A. Pettigrew.

California Honey.—Among the other numerous products for which California seems destined to become famous, honey ranks as by no means the least valuable item. It has already found its way into the eastern markets, though so far in limited supply, and is much admired for its purity and delicacy of flavour. Its production is not limited to any part of the State, but at present it is chiefly made a speciality in San Diego county, near the Mexican border. The honey crop of that county for 1873 was 119,000 lbs., and it is expected it will this year equal 200,000 lbs. The bulk of the honey finds a market in the East. Several car loads were shipped from San Diego East last year, and found a paying and appreciative market, and much more will be shipped this year. The honey made in San Diego is exceedingly white and handsome, and of fine flavour, and commands a good price and ready market wherever offered. Little or no strained honey can be sold during the prevalence of the green fruit season, and it will not be until next fall that any great amount can be moved. The total crop in California this year is variously estimated at from 600,000 to 700,000 pounds.—(*Economist.*)

OUR LETTER BOX.

Fowls Feather-eaters (*E. Smith*).—It arises from the lack of something they would get if they were at liberty, and the feather is the nearest approach to that for which they have the natural craving. Spanish are very prone to it. We have never been able to cure it entirely, but we have lessened it by supplying them with fresh horse dung, lumps of growing grass, with plenty of fresh earthworms and lettuces.

Caponising (*A. G.*).—We never allow it to be practised; and cannot publish directions for one of the most cruel of operations. A well-fed pullet is superior for table to any capon of the same variety.

Various (*Amateur*).—If you wish us to reply the same week, you must send your queries earlier. May-hatched pullets should lay in November or December. Feed them on ground oats or barley meal. Keep eggs where they will be neither heated nor chilled. If you wish to keep them through the winter, you must put them up fresh, and cover them in slaked lime. If for sitting, you may keep them three weeks or a month, but recollect the fresher the eggs when put under the hen the stronger the chickens. In most cases a hen baulked from sitting lays again in from six to eight weeks if during the laying season. To prevent fowls flying the flight feathers may be tied together, or the wing fastened in a brace.

Artificial Swarming (*F. J.*).—We do not advise you to swarm your bees by putting an Italian queen into an empty hive, and placing it on the stand of the old hive with a view to gather-up outside workers, and thus form an artificial swarm. Neither queen nor bees would be disposed to remain in their new habitation if treated in this manner. If the old hive be placed near the old stand most of the bees would find the way to and remain in it. Better and safer it will be for you to drive a swarm into an empty hive, and place the mother hive and swarm some feet or yards to the right and left of the old stand, and if you wish to introduce an Italian queen into your apiary, it could be easily done by giving it to the old hive twenty-four hours after it has swarmed. By that time the bees of the old hive would be found searching for their lost queen, and willing to accept another properly introduced to them. Driving is the most easy, natural, and efficient mode of artificial swarming. In fine weather a swarm may be driven into an empty hive in four minutes.

REMARKS.

28th.—A most beautiful day throughout, very bright and warm. [wards.

29th.—Rather dull early, but soon cleared off; cloudy at noon, but fine after-

30th.—A warm fine day, rather cloudy about 6 P.M.; but fine evening, and bright starlit night.

May 1st.—Cloudy at 2 A.M.; sharp short shower at 5 A.M., and slight rain more or less all day; very thick and dark about 3 P.M.; a dull damp day.

2nd.—Fine morning, but not very bright till after noon; hazy at night.

3rd.—Beautifully fine all day and all night.

4th.—Very fine early, but cloudy by 9 A.M., rather stormlike soon after, and once or twice during the afternoon, the sun shining but little.

A very bright pleasant week, with the exception of May-day, which, for darkness and discomfort might have been November. The mean temperature at 9 A.M. about 8° higher than last week; the underground temperature also rose from 46.1° to 50.8°.—G. J. Symons.

COVENT GARDEN MARKET.—May 5.

The supplies have much improved and business rather better, good hothouse produce being more inquired after as the season advances. Very heavy consignments of Asparagus and salading from the Continent have arrived during the last few days. St. Michael Pines are getting less plentiful.

From observations taken near London during forty-three years, the average day temperature of the week is 65.7°; and its night temperature 43.2°.

CONIFERS IN EXPOSED SITUATIONS.—No. 1.

SITES of residences for the wealthy are occasionally selected having no natural shelter from the winds. Hill-side sites will naturally have shelter from the opposite point of the compass to its aspect, and it may be the prospect is south; the hill will then be a natural shelter from the cold piercing north. But shelter from the nipping east or stormy west is also required. Level or gently undulating surfaces in a flat country are easily sheltered by raising at a suitable distance hills of verdure; for trees, like hills, break the force or divert the course of currents of air. Many trees will be suitable for shelter in a flat country which in a high one are altogether unsuitable. Trees which in valleys attain their full proportions, become in exposed sites stunted in growth. I shall confine my remarks to those Conifers that I have had experience of in a high and exposed situation. Shelter is sought by plantations and belts of trees near and distant, and the first subject to claim our attention is the

Scotch Fir (Pinus sylvestris). It rears its head in stately form, and its roots grip the soil firmly, enabling it to hold its own against wind and weather in positions from which all, so far as I know, of its own order are driven. Stunted it will be if thinly planted, or at a high altitude, for trees diminish in size with altitude and cold, and increase with warmth; but though its head may be a scrub, the branches driven this way and that, the tree does not fail to maintain its equilibrium, and is unquestionably the fittest Conifer for a hill.

Austrian Pine (Pinus austriaca) is of denser growth, and considerably more branched and spreading than the Scotch Fir, the latter making an effort to produce a timber-like stem, to which the Austrian Pine has no pretensions, nor, in my opinion, will this ever be valuable in the most favourable positions as a timber tree in this country. Its growth is dense, and the grip of the soil not nearly so great as in the Scotch Fir. In sheltered positions it grows quickly, forming a spreading tree with dark foliage, and is very handsome. It is also good for planting in the vicinity of towns.

Corsican Pine (Pinus Laricio) is not nearly so dense in habit as the Austrian Pine, and is even less bushy than the Scotch Fir, but it grows twice as rapidly in an exposed situation as either of the kinds mentioned. It rises in the most exposed sites with its main stem as erect as a flagstaff, having every appearance of making a valuable timber tree. In sheltered positions it grows very rapidly, making growths of about a yard in a season. It has a still greater advantage, for though hares and rabbits are very fond of Scotch Fir, and browse on the leaves of the Austrian Pine, these animals never touch the Corsican Pine, which is the very best for any situation for shelter, and I am sanguine also as a timber tree.

We may add to these the Mountain Pine (Pinus Pumilio montana), which is dwarf, and will move any and almost every way without snapping. I do not, however, recommend it. The Sea Pine or Pinaster (Pinus maritima, *Lamarck*) may be mentioned as useful for planting near the sea and for sandy soils; it and the Austrian Pine withstanding the sea winds better than any other Conifer. There is no disputing the value of shelter, especially in exposed situations, so that no apology is needed for introducing a plan of a sheltering belt or plantation.

a.—Austrian Pine at 9 feet apart.
b.—Corsican Pine at 9 feet apart.
c.—Scotch Fir at 9 feet apart.
d.—Larch in the between rows 4½ feet apart, and where planted alternately 9 feet.

The Larches, as nurses, to be all felled by the time they are encroaching upon the evergreens. The removal of the Larches will leave the evergreens 9 feet apart every way, and when these meet, and before they crowd so as to become bare at the bottom, thin to 18 feet apart, and this will keep them feathered to the ground or nearly so, and good for shelter to the longest period. The Larch in exposed situations becomes a scrub, and would never attain to the size of a timber tree were it not for the shelter afforded by the other trees forming the plantation. The pale green of the Larch in spring adds immensely to the beauty of such a belt. The belt ought to be of such a breadth that at least six rows of trees will remain after the nurses are removed.

White American Spruce (Abies alba) has glaucous leaves, and in rather moist soil with moderate shelter grows quickly, and forms a very handsome conical tree. It does not do well without shelter, becoming stunted and sparse of branchlets, succumbing to wind in a bleak exposure.

Hemlock Spruce (Abies canadensis) in exposed situations grows very slowly, the leaves being browned and the appearance miserable. With shelter and in damp soil it thrives well and is very handsome, but it is not nearly so quick-growing nor so beautiful as Prince Albert's Spruce (Abies Albertiana); this, however, does not succeed in exposed positions.

Douglas Fir (Abies Douglasii), handsome and rapid-growing as it is in sheltered situations, does not succeed in high bleak places, its leaves in winter becoming brown and falling in most part before the new leaves are formed, and the tree ultimately perishes.

Menzies' Fir (Abies Menziesii) is quick-growing and ornamental, slightly browned on the most exposed side. The leaves are silvery beneath; it does best in rather damp soil.

Norway Spruce (Abies excelsa) is very dense in growth, and grows very slowly, having after a hard winter a sickly appearance; is not to be recommended unless shelter is present and the ground damp. With those aids it is quick-growing and beautiful.

"Monkey Puzzle" (Araucaria imbricata) does well, the tree retaining its branches near the ground, growing less freely than in sheltered positions, but is better furnished.

Deodar (Cedrus Deodara) is, in an exposed place, cut by the winds, losing its leaves in spring, especially after a severe winter. A number of young plants from seed had from Florence are growing freely, and may be more hardy.

Mount Atlas Cedar (Cedrus atlantica) becomes a spreading tree, the exposure causing it to grow laterally, and yet it is very handsome, very much quicker growing than C. Libani, which does not succeed, becoming a scrub. In moderately sheltered positions C. atlantica grows quickly, and for growth compares favourably with the Corsican and Austrian Pines.

Graceful Cryptomeria (C. elegans), very handsome; its aspect being unique from the chocolate tint of its leaves and branchlets. Winds tell adversely upon it, though in moderately sheltered positions it does fairly. It is said to do well near the coast. C. japonica, by a cold exposure, becomes browned and dwindles away.

Lawson's Cypress (Cupressus Lawsoniana) is slightly browned on the wind side, and especially seawards (east) in the most exposed positions becomes a spreading bush. With moderate shelter it grows freely and is very beautiful. Its varieties are equally hardy and desirable. C. stricta is hardier than C. Lawsoniana, and very much darker in foliage. C. Lambertiana, or macrocarpa, has disappeared.

Chinese Juniper (Juniperus chinensis) grows slowly, but is not cut by the land (west) or sea (east) breezes, and is very ornamental. The common Juniper (J. communis), Irish (J. hibernica), Swedish (J. suecica), have the young growths cut in winter, especially the latter, yet with a moderate shelter they do fairly.

Red Cedar (J. virginiana) grows moderately and forms a fine columnar head, having dark-green foliage. A very distinct and hardy form of Red Cedar is Juniperus virginiana Schottii; it is of fine pyramidal growth, with foliage of a much lighter green than the species.—G. Abbey.

THE ORCHARD HOUSE.

It seems but a few years since orchard houses were in their infancy—when those who undertook to rear these promising bantlings were invited to register facts and to chronicle experiences. I suppose that this pleasing method of fruit culture is now thoroughly understood, and that the art has already arrived at the dignity of a science. The fact has been established that a correct mode of culture commands success; the converse of which proposition is also true—the mode of culture which ends in failure must be the reverse of correct.

Now, I am often asked, Is it worth while to invest in an orchard house? and to this I reply—If you intend to take pains in the application of the rules laid down in the best manuals, and think you have the patience to bear some disappointments, the perseverance to conquer some difficulties, and the spare time to devote to your new pastime, Yes, and I can promise you much pleasure and abundant fruit; but if you are inclined to think that all is done when you have signed your cheque—if you have no intention of personally attending to your trees, but of allowing them to take their chance, as too many amateurs do, why then No. In your case I give the same advice as Mr. Punch did to those about to marry—"Don't." Your trees will be a short-lived luxury to thrips, aphides, red spider, and scale, but to yourself no good at all.

People congratulate me upon my success, but I can tell them it is the result of no small painstaking on my part. I will not say trouble, because the toil is mingled with so much pleasure.

My chief object in writing this letter is to impress upon your less-experienced readers that success in orchard-house culture depends very much upon the promptitude with which the first aphidian incursions are met. The most frequent cause of failure is an apathetic toleration of these pestilent insects in the sweet springtide. Do not helplessly look at them, but take instant measures for their extinction. You must war with them *ab ovo*, or you will never advance *usque ad mala*. Am I extreme in saying that every single tree would perish as a matter of course unless steps be taken for the repression of aphides? No. This should be the first consideration immediately the fly shows itself on the young and tender foliage.

When once the leaves are curled you may know that you are having the worst of the battle. You can then hardly reach the inrolled blighting pest. Before, you might have washed off the embryo brood from every infected leaf with an old shaving brush dipped in pure water. I prefer pure water to boiled quassia chips and soft soap and tobacco water, which if too strong will destroy the aphis, leaf, and all; and then is not the remedy co-extensive with the disease? Yes.

> "To heal disease all tortures are endured,
> A pig is killed that bacon may be cured."

Having neglected pure water (which, by-the-by, must not be applied during sunshine), then nothing will serve your turn but instant and thorough fumigation. Your former dilatoriness has entailed upon you this necessary expense. I, for my part, make up my mind for an annual outlay of one guinea in purchasing Mr. Appleby's compound tobacco paper, which I do not grudge so much as the money I am forced to pay for the terrible and increasing demands of local taxation. I must confess that I have never had such a hard battle to fight with these persistent insects as during the late cold season.

I have no antipathy to the insect as an insect. It must be, I should think, rather a pet with the entomologist. The ant, as Mr. Darwin tells us, extracts a limpid drop of sweetness from its excretions. Its reproductive powers are marvellous, but inasmuch as it is death to my fruit trees I give it no quarter. Nothing but its utter extermination satisfies my repugnance to it.

I feel I must not add to the length of this letter. I will only say that the setting of the bloom on my Peach, Nectarine, and Apricot trees has been eminently satisfactory this year. I enclose a specimen from a cordon tree which, sloping at an angle of 45° on a wall 12 feet high, has been "a thing of beauty," and on it from top to bottom literally every bloom has set; while another tree equally flourishing, grown on the same soil and tended with the same care, has hardly one set blossom on it. Does the reader ask, Why this discrepancy? I answer, For the same reason that there are anomalous nouns and verbs in every grammar.

I must not omit that the emptiness of my tanks shows that the rainfall during the last winter has been inconsiderable in this part of Herts. A second season of drought will, I fear, be very prejudicial to the crops.—A Constant Reader.

[The Peach branchlet enclosed was 5 inches long, and on it were nine well-set Peaches.—Eds.]

AURICULA SHOWING.

The Metropolitan Floral Society deserves credit for endeavouring to restore a correct system of judging, for of late years quantity rather than quality has been considered, and plants with two or three trusses of bloom have had more weight with the Judges than any adherence to properties; but on looking through those staged at the Royal Botanic Society's Show on Wednesday last I noticed that by far the larger number of plants had their flower stems supported by sticks. Now, amongst the older Auricula growers this was never tolerated. It was considered that one point in a plant was that it had a stem sufficiently stout to support the truss, and no artificial support was needed or allowed; and I think the Society would do a good work if it prohibited at its next exhibition anything of the kind.—An Old Fancier.

WINDOW GARDENING.

The management of plants is, I fear, but little understood by those who strive to cultivate a few homely flowers, and whose only garden is the window-ledge, and I am induced to offer the following suggestions in the hope that they may prove of some value to readers of humble horticultural pretensions, and assist them to preserve their plants in a healthy state.

The leaves of plants perform most important functions—viz., the exposure of the fluids to the influence of air and light, and the absorption of carbonic acid and moisture from the air by means of pores on their surface. It is most important, therefore, that they should be kept free from dust, which by closing the pores interrupts their functions and injures the health of the plant. I frequently observe the plants in window gardens encrusted with dirt and presenting a most sickly appearance, doubtlessly attributed by the owner to any cause but the right one.

The best method of cleansing plants is by syringing, or in the case of plants with smooth leaves by sponging. After syringing overhead the plant should be inverted to clean the under side of the leaves. By attending to the foregoing rule

I am enabled to preserve a healthy collection of plants in a locality where smoke and dust are plentiful.

It is a common custom to colour the pots in window gardens with red lead or other pigments in order to give them a bright and neat appearance, but this practice is especially detrimental to the health of the plants, the pores of the pots being closed and the evaporation stopped. If the pots stand in saucers care should be taken to allow no water to remain in them, as it would soon injure the roots by stopping the drainage. The best pots are those which are slightly under-burnt, and consequently soft and porous.

The soil in town gardens is generally unfit for potting purposes, having a tendency to set hard if allowed to become dry, and by contracting to crush and tear the tender rootlets of the plant growing in it. I would, therefore, strongly recommend readers to purchase their potting soil from the nearest nurserymen, who will supply them with the proper mixture at a trifling charge.

In conclusion I would warn all amateur gardeners against purchasing plants in bloom from hawkers in the streets; such plants are generally forced into bloom, are sold at a high price, and last but a very brief period, whereas strong healthy plants of Geraniums, Calceolarias, &c., can be purchased in the market, or from nurserymen, for 2*s.* 6*d.* per dozen, and after being repotted will come into bloom and last the whole season.—Edwd. Geo. Rivers.

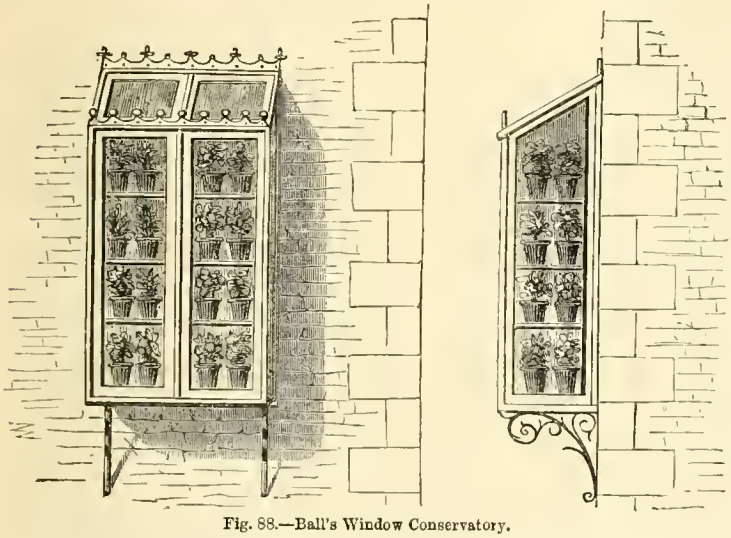

Fig. 88.—Ball's Window Conservatory.

[To avoid exposing plants to the destruction of a gas-heated room we commend to the attention of our readers "a window conservatory." This is a contrivance of Mr. F. W. Ball's, contractor, Sussex Street, Norwich. It can be made of any size, and is easily fixed to the outside of a window-frame. The comfort of the room is increased in winter by its shutting-out the cold, and is cooling in summer, a continual current of air being kept-up outside the window by the ventilation of the conservatory.—Eds.]

LATE-KEEPING GRAPES.

If twenty Grape-growers, taken at random, were asked to name the best late-keeping black Grape, it is very probable that nineteen of them would select Lady Downe's Seedling, but it is questionable if all of them could give a satisfactory reason for doing so. I have been much puzzled to account for the popularity of this Grape, and have come to the conclusion that it is simply owing to its being better known than some other kinds, one or two of which are, in my opinion, very superior to it. Let us look at its merits, and then try the effect of comparison with others. It is vigorous in growth, with stem, branches, and foliage large and of great substance. It starts into growth freely and well, is very prolific; the berries set freely, are large, colour well, continuing plump and in excellent condition till spring. So many points of excellence ought, of course, to receive the attention which they merit, and they have undoubtedly done so; but then, on the other hand, the bunches, though so numerous, are neither large nor handsome; they are long and slender, with very slight shoulders. I ought not, perhaps, to say this is invariably the case, for I once had a bunch with really fine shoulders, but I have never had or seen another, and slender bunches are certainly the correct type. It is not, however, from the size of the bunches that I would condemn this Grape, but for its tendency to suffer from the scalding of the green berries, and which is only to be cured, or rather checked, by letting in fresh air freely and constantly for a week or more, and consequently reducing the temperature. This treatment is all very well if there are no other sorts of Grapes in the same house, but in mixed vineries it is very objectionable, especially if there are any Gros Guillaume or Muscats, all of which are so liable to suffer serious harm by being thus suddenly subjected to a sustained low temperature when the fruit is swelling.

In a late vinery I have Lady Downe's Seedling, Black Alicante, or Black Tokay as it is sometimes called; Gros Guillaume, Mrs. Pince's Muscat, Madresfield Court Muscat, and Frankenthal, all planted inside, but with the roots passing under arches in the front wall into an outer border. The Vines are in excellent condition, and have been in full bearing for two years, so that the estimate which I have made of their relative merits will prove a safe guide for future measures.

The sort which, in my opinion, bears the palm as the best late-keeping Grape for the general practitioner is Black Alicante; it is equal to Lady Downe's Seedling in the vigour of its growth, while the size of its fruit is altogether superior to that variety in its large heavily-shouldered bunches, and its perfect immunity from scald or shanking. The bunches are invariably too numerous, a considerable number always having to be taken off, and every berry appears to set and swell. I am inclined to think that this fine Grape would long ago have taken the place of Lady Downe's if its value was better known. That is the point. The true kind is not well known, and there is no doubt that Black Morocco or Kempsey Alicante has crept into many vineries under the title of Black Alicante, only to disappoint those who, supposing it to be the real Simon Pure, conclude that they have been misled by a fanciful and untruthful description, and discard it in disgust; for although Black Morocco is a fine-looking Grape and hangs well, there can be no greater contrast than in the setting properties of the two kinds, the true Black Alicante setting its fruit most freely, while it is a very difficult matter to induce the other variety to set at all. The whole of the Vines under my care were had from Mr. Pearson of the Chilwell Nurseries, near Nottingham, and being certain that I have the true Black Alicante, I append Mr. Pearson's description of it in his valuable little book on Vine culture:—"Black Alicante. A noble variety when well grown. As several inferior Grapes are grown under this name, I will describe the true sort: A vigorous grower, with large downy foliage. Bunches large, heavily shouldered like the Black Hamburgh. The footstalks of the berries very strong and thick. Berries very large and black, covered with a fine bloom. Skin thick. Requires almost as much heat as a Muscat of Alexandria, and is then a first-rate Grape and one of the best keepers."

I would call especial attention to what Mr. Pearson says about heat, because it is owing to a deficiency in this respect that late Grapes so often lack flavour and keep so badly. Take for example that noble Grape Gros Guillaume. In the temperature of a Muscat house its large handsome foliage borne on wonderfully vigorous wood that is laden with magnificent bunches, often measuring 18 inches in length and 15 inches across the shoulders, the berries very large, of a deep black colour, and of a singularly piquant rich flavour, mark it for a king among the late Grapes. Without the advantage of the high temperature its fruit is comparatively worthless—nay more, there is often no fruit at all. A comparison of the two methods of treatment will serve to explain this.

By the first the application of artificial heat follows the first signs of growths, but does not precede it, and a steadily increasing temperature is maintained till the bunches are in

bloom, by which time the maximum of 75° by night and 85° by day is reached. After the fruit is set it is reduced to 70°, and kept there till the fruit is well coloured and the bark of the wood of a bright reddish brown hue, after which the valve is only turned on to dispel damp or keep out frost. Thus a double purpose is accomplished: the crop is in a finished condition, and will continue fit for table till spring, and well-ripened fertile wood is secured for the ensuing season.

By the second method there is no systematic application of artificial heat, or rather the heating apparatus is not used at all till late in autumn, from an erroneous impression that the growth of late Grapes should be retarded as much as possible. The result is badly-coloured fruit of a poor insipid flavour, discreditable to the grower, and certainly distasteful and unsatisfactory to the consumer; soft, pithy, unripened wood, pointing to barrenness and failure in the next season.

This is not a fanciful picture. How frequently have we been told that Gros Guillaume is worthless—a shy-fruiting sort, occasionally bearing large bunches of unsightly flavourless fruit. And how pleasant is the feeling—nay, it is a veritable triumph, when the excellence of really well-grown fruit becomes fully realised. Certainly erroneous impressions are very prevalent concerning this Grape; one of them is that it must be grafted in order to induce fruitfulness. Even Mr. Pearson asserts that it "is improved by grafting on the Hamburgh," and I have been gravely informed by others that it is impossible to obtain full crops from ungrafted Vines.

Now, a mere glance at it when in full growth ought to convince anyone that grafting would be an evil even if it were necessary. The large bulk of the stem and canes, the stout, vigorous, long-jointed branches, with foliage and fruit bunches of an unusual size, are all admirably proportioned, and yet we are told that it is necessary to check this vigour, to upset this balance of Nature, by grafting it upon a sort that is not naturally so vigorous. One would think that the fallacy of such reasoning would strike the dullest intellect. Oh for an entire house of Gros Guillaume upon its own roots, which could ramble unchecked and free in a wide border of sound rich soil. What a sight would it present when in full bearing! The wide-spreading branches clothed with broad foliage, and bearing huge bunches of deep purple-skinned fruit. What breadth of shoulder, and yet how symmetrical! But I must not go farther, the picture would be too tantalising; it is, however, none the less certain that it could be fully realised, for if one or two Vines can be made to produce full crops of fine fruit year after year in a mixed vinery, it follows that the culture of an entire house of it would be still easier.

One other matter must not be forgotten, and that is not only to ripen the wood thoroughly, but to retain two or three joints of it on every lateral spur, pruning to a full plump bud. Here Nature again clearly points the way. She gives us a plant of extraordinary vigour, and if we try to confine its growth or to reduce it within the bounds wisely assigned to others of weaker growth, we ought not to feel surprised if such faulty treatment leads to failure.—Edward Luckhurst.

THE COLOGNE INTERNATIONAL EXHIBITION.

The General Committee of this Exhibition wrote as follows:

"To the Royal Horticultural Society of England.

"Gentlemen,—A letter from Lord Odo Russell, the British Ambassador at Berlin, informs us of your having courteously intimated that the Council of your esteemed Society would be ready to act as a Committee on behalf of British exhibitors at our forthcoming International Exhibition, and that it would also send a representative to the same.

"We now take the liberty to address you direct on this subject, and before all we beg to state that we shall be very happy to accept your kind offer, by which you will be putting us under great obligations, and that we shall thank you to inform us of the names of those gentlemen who will kindly take the matter in hand, so that we may insert them in the catalogue to be issued, as forming the English Special Committee, in the same manner as we shall publish the committees formed in other foreign countries.

"We are sending you by book-post general programmes as well as the special regulations of our Exhibition. If you should require any more of these they will with pleasure be at your service.

"We do not at the same time send you application-forms for entries, because we should first like to hear from you whether you will undertake to attend to this matter, or direct to us any exhibitors applying for the same, which we suppose would be more convenient to you.

"In our opinion it is especially desirable to see the English manufacturers of objects relating to garden architecture, machinery, &c. (divisions III., IV., and V. of our programme) entering competition, and we beg you will kindly draw also their attention to our undertaking. Further there are fossil plants and their fruit stands (see special programme VI. *c*), of which we should be highly pleased to get a collection sent from your country. These latter are no doubt abundantly found in the coal and turf pits of Wales, &c., and perhaps there are collections of this kind in the royal museums, which Government might be induced to send to our Exhibition.

"Our undertaking which already thus far promises to take very large dimensions, has found ready subvention on the part of the different Governments as well as from the public in general. Most of the railway and steam navigation companies have reduced the freight on goods to be sent to the Exhibition by 50 per cent., and there is no duty to be charged on such objects unless they should be sold here and remain in the country.

"For English exhibitors it will be of special interest that the Netherlands Steam Navigation Company and the Belgian Company whose steamers ply respectively between London and Rotterdam, and Dover and Ostend, as well as the Rhenish Railway Company are of those who have granted the before-mentioned reduction.—B. Edward Oppenheim, *Sec.*"

Responding to this application, the Royal Horticultural Society have appointed a Committee, consisting of W. Burnley Hume, Esq., W. B. Kellock, Esq., Robert Warner, Esq., and Dr. Hogg.

ROYAL HORTICULTURAL SOCIETY.

May 12th.

The third Exhibition of the season was favoured with a brilliant day. It is designated the Pot Rose Show, and as such we dispose of it by saying that Mr. J. Herrington, gardener, Larkbere, Thornton Road, Clapham Park, staged six plants and a box of twelve cut blooms, for which he had first prizes. That completes the Roses for five classes; but, as an extra, Mr. W. Paul sent a collection of cut blooms, which were much admired. But still there was a flower show, for the collections of hardy plants were a show in themselves—small it may be, but yet not only interesting, but intrinsically beautiful.

For eighteen hardy perennials in pots were staged three good collections. Than these fine plants nothing in the Exhibition was more effective. Even a conservatory half filled with such plants would be a grand sight; but their chief merit is that they are adaptable to any garden, and their extended cultivation cannot be too strongly recommended.

The most telling pots in the collection of Messrs. W. Rollisson and Sons, Tooting, who were placed first, were Trillium grandiflorum, paper white, very fine; Phlox Nelsonii, a dense low mass of scented pinkish white flowers; Gentiana acaulis, exceedingly rich violet purple; Primula cortusoides amœna, splendid, and A. lilacina; Gentiana verna, dwarf, rich blue; Iberis corifolia, Polygonatum multiflorum (Solomon's Seal), with Iberises Iberica, most beautiful, and Lady Jane, a large plant of Dielytra spectabilis, and Saxifraga siberica. Second honours were awarded to Mr. R. Parker, Tooting, who had a charming group; the best were Phlox setacea violacea, P. frondosa, and P. divaricata, Gentiana acaulis, Anemone nemorosa flore-pleno, Euphorbia pilosum with golden green bracts, Iris nudicaulis, Orobus vernus and O. albus plenus, Adysetum (Alyssum) orientale, Saxifraga palmata, Primula elatior Golden Plover, Caltha palustris flore-pleno, deep yellow; Scillas, and Dielytra. Mr. R. Dean, Ealing, secured the third prize with, amongst others, Aubrietia Eyreii, an exceedingly fine variety, invaluable for spring bedding; Lithospermum prostratum, Pansy Sulphur Queen, crimson and white Daisies, Cheiranthus hybridus, and C. alpinus; also Pinguicula grandiflora, an insectivorous plant, the flat Auricula-like leaves being covered with dead insects. It has beautiful spurred flowers surmounting a stem 4 inches long; it is purple in colour, and in form not unlike a Mimulus. For nine bunches of hardy perennials, cut blooms, Mr. R. Parker, Tooting, was first with pots of Aponogetum distachyon, Iris germanica, Trollius napellifolius, Spiræas, Alysaum, Tulips, Scillas, &c. The flowers were inserted in sand in 32-sized pots. Second went to Mr. Dear, who had a collection in smaller pots. We have now noticed the most attractive portion of the Exhibition, for these simple hardy flowers have fairly won the place of honour.

In the Azalea classes there was scarcely any competition. The best plants were staged by Mr. J. Herrington, gardener, Larkbere, Thornton Road, Clapham Park, who secured the first prize with well-bloomed medium-sized plants of Sir C. Napier, Criterion, Iveryana, Stella, Duc de Nassau, and Flag of Truce, and had the first prize, second honours going to Mr. Colea, gardener to W. K. Wigram, Esq., St. Margarets, Twickenham. Messrs. Dobson & Sons also exhibited a miscellaneous collection of very good plants, in which Reine des Doubles was the most effective.

For nine Calceolarias (open), Messrs. Dobson & Sons were

first with dwarf massive plants with large well-coloured flowers of good form and of great merit, the varieties were Crown Prince, Unique, Magnificent, Achievement, Hamlet, Canary, Admiration, Enchantress, and Sir R. Napier; Mr. Clark, gardener to W. Shuter, Esq., Hampstead, being second with larger plants and very good; the third prize going to Mr. Herrington, gardener, Thornton Rise, Clapham Park. The class for show Auriculas was empty; for Alpines, Mr. Dean and Messrs. Dobsou & Sons staged small plants, and had first and second prizes respectively.

Mr. S. Coulter, gardener to L. J. Baker, Esq., Haydon Hall, Middlesex, exhibited splendid pyramids of Mignonette 4 feet high and 2½ feet in diameter at the base. The plants were trained on wire trellises, and covered with medium-sized trusses from base to apex. Mr. F. Barnes, gardener to A. Chancellor, Esq., The Retreat, Richmond, staged smaller plants extremely good in foliage, and covered with splendid spikes. These collections were excellent examples of culture, and merited official recognition.

Messrs. James Carter & Co. exhibited fine pyramids of bouquet Mignonette, excellent alike in culture and quality; a basket of the distinct and brightly painted Coleus Duchess of Edinburgh, and variegated Musk. A gay miscellaneous group of decorative plants were also brought from the Society's Gardens.

Fruit Committee.—Henry Webb, Esq., in the chair. Mr. James Batters, gardener to Mrs. Willis Fleming, Chilworth Manor, Romsey, Hants, sent a collection of forced vegetables, which were much discussed, as they were grown in 8-inch pots, and therefore were considered by the Committee to possess great interest to those having small gardens. A cultural commendation was unanimously awarded them. Excellent bundles of Connover's Colossal Asparagus came from Mr. Dancer of Chiswick, and Mr. Allen, gardener to Lord Suffield, Gunton Hall, Norwich.

From Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., came a collection of well-kept Apples, to which a letter of thanks was directed to be sent. A fruit of Sephanotis floribunda came from Mr. Welsh, gardener to B. T. Coombe, Esq., Taunton. A dish of Beurré Rance Pears was sent by Mr. Coles, gardener to W. K. Wigram, Esq., Twickenham. A letter of thanks was awarded on account of their being so well kept. They were also of very good flavour.

A basket of Morels was sent by Mr. Barclay, gardener to the Earl of Rosebery, The Durdous, Epsom. These arrived too late to be placed before the Committee, which is to be regretted, for they were very fine indeed.

Floral Committee.—Dr. Denny in the chair. A first-class certificate was awarded to Mr. Louis Van Houtte, Ghent, Belgium, for Bertolonia Van Houttei; the colour of the leaves is browniah green, the venation being relieved by pinkish steel-blue glossy streaks of metallic lustre. It is a charming plant. A first-class certificate was also awarded to Mr. Wm. Paul for his fine Rose Star of Waltham; it is a noble Rose with great substance of petal, good colour, splendid foliage, and, what is more, delicious perfume. Mr. B. S. Williams sent Azalea Flambeau, a rich crimson scarlet and fine for decorative effect, to which was given a second-class certificate. A botanical certificate was awarded to Mr. Green for Senecio macroglossa, an Ivy-leaved-trailing plant, with large straw-coloured, Daisy-like flowers. Cultural certificates were awarded to Mr. Braid for Pelargonium Duchess of Edinburgh, very dwarf and free; and to Mr. Miles for hybrid dwarf Mignonette, of extraordinary vigour and high perfume. A vote of thanks was given to Messrs. Veitch & Sons for Pinguicula grandiflora, an interesting and also pretty insectivorous plant. Messrs. James Carter & Co. sent Gloxinia Duke of Connaught, a fine seedling, rich and good. Mr. Laing sent Caladium Madame de la Derausage, and Mr. Pounce Lomaria Pounceii.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Crocus chrysanthus. *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia.—"Mr. Elwes, F.L.S., gathered it in Asia Minor, probably (he tells me) near Smyrna, in March, 1874. Here it was originally discovered by Friwaldsky, and collected later by Balansa, who observes that it is abundant on hills about 3000 feet high, flowering in March. It has also been found in Macedonia and Thrace by Grisebach. Besides its delicate lemon colour, C. chrysanthus has its sweet odour to recommend it; and it appears to be a very free bloomer."—(*Bot. Mag.*, *t.* 6162.)

Odontoglossum Warscewiczii. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Flowers white, with light purple blotch at the base.—"O. Warscewiczii was discovered by Joseph von Warscewicz, the Polish nobleman who has added so many fine plants to our stoves, in Costa Rica; it was first flowered by Messrs. Veitch in February of this year. It is a very free bloomer, and may, as Dr. Reichenbach suggests, rival O. vexillarium itself in the estimation of florists. Its discoverer describes it as growing at a considerable elevation, and being very scarce."—(*Ibid.*, *t.* 6163.)

Hemichæna fruticosa. *Nat. ord.*, Scrophulariaceæ. *Linn.*, Didynamia Angiospermia. Flowers yellow, with crimson anthers.—"A very handsome rock plant, but not likely to be hardy; found originally by Hartweg in Guatemala, and described by Bentham in 1839 as a new genus, which, however, he immediately after, but on insufficient grounds, merged into Leucocarpus.

"Nothing further was known of Hemichæna till it was sent from Costa Rica by Endress, plants from whom flowered at Messrs. Veitch's establishment, July, 1873. Osbert Salvin, F.R.S., an able ornithologist and assiduous collector of plants, next found it growing on the Volcan de Alitan in Guatemala, at an elevation of 10,000 feet above the sea."—(*Ibid.*, *t.* 6164.)

Galanthus Elwesii. *Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. Flowers white.—"A native of the summits of the Yamanlardagh mountains, north of the Gulf of Smyrna, where it was discovered by M. Balansa in 1854, and whence dried specimens were distributed under the name of G. plicatus, being so named by M. J. Gay of Paris. I am indebted to Mr. Elwes, of Miserdine House, Cirencester, a gentleman who to an ardent love of scientific horticulture unites the powers of a traveller, collector, and observing naturalist, for pointing out its distinctive character from G. plicatus, and which Mr. Baker has confirmed. Mr. Elwes collected specimens on the mountains near Smyrna in 1874, and cultivated them in his garden at Miserdine, which bids fair soon to contain perhaps the largest and best private collection of well-named bulbous plants in the kingdom. It flowered in February, and is quite hardy."—(*Ibid.*, *t.* 6166.)

E. G. HENDERSON & SON'S, WELLINGTON NURSERY, ST. JOHN'S WOOD.

Amongst English nurseries this establishment holds high rank and a familiar name. It is not a great nursery in the way of external grandeur, or by a limited number of perfected specimen plants of immense size and great individual value. It is not a nursery that confines its resources to the multiplication of plants to meet the popular demand of the hour. In a word, it is not great for what some other nurseries are justly held in high repute, but it has a greatness of its own of a sober kind, and occupies a distinct niche in the world of commercial horticulture. A glance is only needed to find that the characteristic of the establishment savours of a botanical collection. For variety especially, also for number of plants, the nursery holds the highest position. Not in one, but in every department is it replete with portable plants of sturdy vigour and clean, ready at all times to be distributed by thousands at home and abroad. Orchids, Ferns, Palms, hard and softwooded plants, bulbs, alpines, and herbaceous plants, are all represented in great numbers. It is, in fact, a plant manufactory on a large scale, and reminds the visitor of the Belgian emporiums, where plants are grown for sale rather than for show. The immediate object of our visit was to inspect the grand display of Tulips now flowering in the nursery, but we will first briefly glance through the houses.

The most striking feature is the cool temperature under which Orchids and other stove plants are grown. There is no tender nursing, but the plants are grown in as low a temperature as is consistent with their health, so that at all times they are prepared to endure even long voyages with a minimum amount of injury in transit. Palms, especially the cheaper varieties, are grown by thousands with little or no artificial heat, while large stocks of the choice sorts, such as Cocos Weddelliana and Geonoma gracilis, are flourishing in an intermediate temperature. Orchids are exceedingly numerous in small plants. They are also slowly grown under all the sun and air they will bear, and are in a healthy hardy state. Importations are continually arriving, thousands of plants still unpotted being laid under the stages and on the paths to become freshened after their long journey. A heavy consignment of Odontoglossums, O. Alexandræ, O. Pescatorei, and O. Wallisii were just potted and placed on latticework, over water, with a current of air night and day passing over the plants. Dendrobium Wardianum and Masdevallia Lindeni have also just arrived in large numbers.

In one of the houses is a large flowering plant of Hæmanthus Roperi (syn. Cooperi), its fiery globular heads being very effective. It is very similar to H. insignis. Crinum ornatum

africanum, a variety with several synonymes, is in flower, and surrounded with a large stock of young plants. Cupania filiciforme is freely growing in immense quantities. Ipomœa Horsfalliæ is blooming freely, and is very rich. As an example in the way of Ferns are 1400 Adiantum Farleyense growing without shade or artificial heat. Tabernæmontana camassia is extensively grown. It is a Gardenia-like plant, flowering freely even in thumb pots. For table decoration Dracæna gracilis, an elegant Grass-like variety, is in great repute.

Amongst new plants of notice are a trio of Sonerilas—S. Hendersonii, S. marmorea, and S. argentea. These have large leaves, silvery, and are a great improvement in this class. Bertoloniss are also in the glowing colour indicative of good health. A new plant of great elegance for table decoration is Sonchus elegantissimus. It should be called the Grass Fountain Plant by its delicate arched sprays of bright green exactly resembling a fountain. It is not yet in commerce.

In the herbaceous garden Euphorbia pilosa is a mass of yellow by its golden terminal bracts. It grows about a foot high. The varieties of Primula cortusoides are also in beauty; also Violas, the earliest for bedding being V. pallida, a primrose-coloured variety.

The Tulips, though on the wane, are still a gorgeous sight, as 20,000 bulbs bedded-out must be. The best are Couleur de Cardinal, dwarf, massive, and brilliant; Proserpine, carmine; Rose Luisante, beautiful rose and fine; Brutus, fiery scarlet; Vurbask, ruby crimson; Yellow Prince; Duchess de Parma, crimson and gold; Eleonore and Wouverman, violet purple; Queen Victoria, white; Bride of Haarlem, scarlet flake, dwarf; Crown of Roses, a fine double; Extremite d'Or, like the double Tournesol, and Rex Rubrorum. These are only a few of this splendid collection, and the above is only a mere cursory glance of this well-furnished nursery.

NOVELTIES IN THE ROYAL GARDENS, KEW.

Saxifraga peltata, one of the largest as well as one of the most distinct and interesting of this favourite genus, is now in flower in the herbaceous ground. It is the only species known as having truly peltate leaves, and from this character Engler, in his Monograph, formed for it a distinct section, which he called Peltophyllum. The rhizome is creeping, by the division of which propagation is effected. The leaves are deciduous, and appear soon after the flowers; the petioles are erect, 1 to 2 feet high, supporting an orbicular blade 6 inches or more in diameter, depressed in the centre, six to ten-lobed, toothed and laciniated. The pretty pale pink flowers are produced in capitate cymes 3 to 5 inches in diameter, on scapes which about equal the leaves. Though little can be said in its favour from a purely decorative point of view, it must yet be considered as decidedly essential to the alpine or herbaceous collection. It is a native of California, and was figured in the "Botanical Magazine" of January last year. So far it has proved quite hardy, and is best treated as a sub-aquatic.

Iris olbiensis, also figured in the same volume, is in flower. It is a good ornamental species of dwarf habit, being not more than 6 to 8 inches in height, and with very large flowers in proportion to the plant. They are dark purple, and when extended measure about 4 inches across. It is a native of northern Italy and southern France, and in cultivation is rare.

The Rockwork commences to exhibit in flower many of its choice occupants. Among the foremost in brilliant colour is the rare liliputian Wallflower Erysimum pumilum. It is scarcely 2 inches in height, and is covered with beautiful yellow flowers, much like those of Cheiranthus alpinus. It is fit for the choicest company, and should have a raised position on rockwork. From seed it is easily grown. A native of the Alps and Pyrenees. Near this the choice Omphalodes Luciliæ is commencing to grow. In a suitable position it is not so delicate as usually imagined. Like many others of similar nature it is almost sure to die if planted on the ground level, but when raised a few feet it is comparatively safe.

Dwarf and pretty Alpines are always in demand; of this character are Romanzovia sitchensis and R. unalaschkensis, both of which are in flower, and much resemble Saxifrages. They have white flowers, the former with pale green orbicular-reniform leaves and succulent stems, reaching a height of 6 inches. It is a native of north-west America. R. unalaschkensis is less robust and dwarfer, with reddish stems and leaves of darker green. It is a native of Russian America. They have been but recently introduced, and are little known, but may, however, be recommended with confidence.

The next demanding attention is a new Lewisia, L. brachycalyx. From all that is known of L. rediviva (see page 485 of June 18th last year), another species can but be received with interest and pleasure. It has a similar habit, though apparently more robust, and producing a greater number of flowers. They have a fewer number of petals, are somewhat smaller and paler in colour. The leaves at once distinguish the two, being in this narrowly spathulate instead of terete or compressed. It is a native of the same region as L. rediviva.

A very good tuft of Androsace imbricata is beautifully in flower. The pure white flowers, from the shortness of the petioles, seem to be seated on the silvery cushion of leaves. This and other perennial members of the genus delight in having their rosettes supported by pieces of stone, so as not to be in contact with the soil. Arabis blepharophylla is just coming into beauty. It is scarcely new, having been introduced in 1865, though it was only figured in the "Botanical Magazine" last year. Its splendid rose-coloured flowers render it a worthy subject of cultivation. It is best raised from seeds, when good plants are soon obtained with little trouble. In passing we observe Chlorogalum Leichtlini, long erroneously known as Camassia alba.

In the Economic house Meninia turgida represents a new plant, and also a new genus of Acanthaceæ. It is somewhat ornamental, and flowers very freely. In habit it is much like Eranthemum, but is better furnished with branches. The flowers are produced in dense terminal spikes or in panicles; they are short and stout, peculiarly reticulated on the inside, with pinkish brown nerves. Its place in this house is due to its being a celebrated febrifuge in its native country, Cochin-China, where it is called Thuong-sou by the natives. It was sent to Kew by Professor Décaisne, flowered in April of 1873, and was figured in July of the same year. The temperature of an intermediate house or stove is necessary for its cultivation. In the Succulent house Sedum Alfredii is extremely pretty in flower. It makes a good basket plant from its free growth and bright green colour, with brilliant yellow flowers, about this time of the year. It is a native of China, and was introduced to Kew some time ago, but has not yet been widely distributed.

Brownea grandiceps is flowering in the Palm house. In colour it does not vie with B. coccinea, but far surpasses that species in its immense trusses of bloom, sometimes 8 inches in diameter. Dr. Lindley mentions an interesting peculiarity concerning the leaves, but which this plant does not seem clearly to show: "Every evening they rose up and lifted themselves from the blossoms to expose them to the dew, so that each morning these beautiful objects were uncovered; but as day advanced the leaves gradually drooped and bent down over the flowers to guard them from the rays of the sun."

LITHOSPERMUM FRUTICOSUM.

A correspondent, "W.," has on page 331 directed attention to the hardy evergreen trailer Lithospermum prostratum, which is really a rich and elegant plant for the spring garden. I beg to name L. fruticosum as still richer in colour, and in all other respects equal to the species to which "W." has referred. L. fruticosum is of more shrubby and erect habit, is a deep, rich, full blue—unequalled in its way by any other flower of the period. It is most profuse in blooming, and its bright sprigs are eminently adapted for bouquets—indeed I believe it is used by some bouquetists rather extensively. Grown as a pot plant for indoor decoration it has a distinct and telling effect amongst the usual occupants of the conservatory, and will contribute a feature to a collection quite worthy of recognition. It is of very easy culture and ought to become popular, which it will do when better known and properly grown. If "W." had seen the miniature staudard plants exhibited by Messrs. E. G. Henderson at the Regent's Park Show on the 28th ult. he would, I think, have awarded them at the least equal praise to that he justly bestowed on L. prostratum. This is a genus of hardy spring-flowering plants of great merit, and only requires to be known to be universally cultivated.—J., *Clapham.*

A Monœcious Aucuba.—A friend lately directed my attention to an Aucuba japonica covered with berries, the blossoms of which had not, he said, been artificially fertilised, nor was he aware of any male plant in the neighbourhood. On examination I found one branch on the lower part of the tree had male flowers, while all the other blossoms were the ordinary female

blossoms of the common Aucuba. Is not this a very unusual circumstance?—John B. Boyd.

[We never heard of a similar instance.—Eds.]

FLOWERS FOR OUR BORDERS.—No. 49.

BRAVOA GEMINIFLORA.—Twin-flowered Bravoa.

The Bravoa geminiflora is a half-hardy plant, producing a tunicated bulb, about the size of a moderately large Hyacinth root, but more elongated. From this bulb proceed three to four pointed leaves, 18 to 20 inches or more long, and from 1½ to 2 inches broad; they are keeled at the back, and usually quite erect. The scape or flower-stem springs directly from the bulb, and is not uncommonly from 3 to 4 feet high, of a round tapering form, and bearing several pointed half-sheathing bracts arranged alternately at distances of 5 or 6 inches from each other.

Fig. 89.—Bravoa geminiflora.

The raceme of flowers terminates the stem, and consists of about sixteen pairs of blossoms, at the base of each of which is a small trifid bract; in the early stages of their growth they are quite erect, and pressed close to the scape, but as they expand the tube of the flower becomes gradually curved outwards, until at length its mouth points downwards. Each flower is about 1 inch or 1¼ inch long, of a cylindrical form, and divided at its mouth into six short, rounded lobes, which, when the flower is fully developed, are slightly spreading; at this period their tint is a delicate salmon or flesh-colour, tinged with green at the base, where the perianth coheres with the seed-vessel.

The Bravoa may be cultivated either as a window bulb or in the open border, where it succeeds perfectly in a warm aspect and suitable soil. The only objection to its cultivation in the window is its liability to become "drawn" from deficiency of light and air; but, in all other points, no plant can be more manageable. It should be potted in a good friable loam, with which a little silver sand should be mingled, unless the soil contains naturally a fair proportion of silicious matter. This is necessary to ensure the requisite porosity; but, unless a considerable proportion of good loam is also present, the growth of the plant will be weak. The bulb should be planted with its neck level with the surface of the soil, in a 4 or 5-inch pot, which will be found amply sufficient, except for the largest bulbs. During the winter months, when the plant is dormant, the soil may be kept nearly dry, but when in activity it requires to be freely watered. It usually commences its growth about the end of April or beginning of May; and, in a warm window, will make rapid progress, producing its flowers about the end of July. After the blossoms have faded the pot should be placed out of doors in a sunny situation to ripen the bulb, and when the foliage has decayed it may be returned to its winter quarters, which may be any airy place inaccessible to frost.

In the open ground its treatment may be inferred from what we have just stated. If planted out in April, while dormant, it should be covered with a hand-glass to protect it from spring frosts; if kept on the window or in a cold frame until the middle of May it may then be plunged into the borders without this precaution. In this situation its height will be less than under glass, and the colour of the flowers deepen to red. It is easily increased by offsets, which may be separated every second or third year, and also by seeds, which may be ripened in the greenhouse or window if the plant is grown on after flowering.

The Bravoa geminiflora is a native of Mexico. Its name was conferred in honour of the Mexican botanist, Bravo.—(*W. Thompson's English Flower Garden.*)

THE THAMES EMBANKMENT.

Without further ceremony than a walk round by the members of the Board of Works another portion of garden enclosure was on Saturday last declared by Mr. W. H. Smith, M.P., to be open to the public. The new garden is immediately west of the Charing Cross railway station, and is a little over two acres in extent. It is laid out artistically, yet with special regard to the purpose of free and easy promenade. The walks are ample, soundly made of asphalte loosely surfaced with light gravel, and are edged with Ivy. A main walk is taken round the enclosure in a serpentine manner, with curved cross walks enclosing shrubberies, lawns, and flower beds, the parts being agreeably proportioned. There are forty-eight flower beds, which will require about fourteen thousand plants. The trees comprise Lombardy Poplars, Planes, and weeping trees, with shrubs which experience has proved suited to the site. The borders at the entrance are brightened by Intermediate Stocks. The garden is from the design of Mr. Vulliamy, and executed by Mr. Meston. It is well conceived and carried out, and likely to be the most artistic portion of the Embankment. The lawns and shrubs on the established portions are in excellent order; the beds are gay with Tulips, the whole reflecting credit on Mr. Sinclair's superintendence.

IN SEARCH OF SPRING.

I do not know what sort of weather you are having in London, but here we have had nothing but a succession of cold easterly winds. I never saw vegetation so backward: no trees are in leaf, the grass is green but does not grow at all, and my Roses have hardly began to move. We are within two months of the Palace Show, and the greater portion of my maiden Briars have not started. The farmers round here are driven frantic; they have no hay left, and they cannot afford to buy any at £8 a ton, so the stock are grazing on the fields which should be laid up for mowing. In fact, I never saw things look more serious than they do now, for if we have another dry summer, we, who live in this wretchedly poor dry soil in Dorset, will have no hay for next winter.

This being our state here, I thought I should like to go into Cornwall, to the most southern and western points of England, and see if I could find signs of spring there, and so, having arranged my duty for one Sunday, I set off the first day for Plymouth. Here I found it colder than at Monkton Wyld, and the country equally backward. Mount Edgecumbe looked as if we were in midwinter, the Hoe was as desolate as Salisbury Plain—the very water of the Sound was of a cold grey colour instead of the lovely silvery-green which one is accustomed to see. I went from Plymouth to Falmouth by the Irish steamer, thinking I should find the warmest town in England an exception to the general rule. But never was I more mistaken, and never was I colder than at Falmouth. I went to look for the Lemon trees which grow out of doors, and I found one which was just beginning to start into life. The gardener said they had never known such a winter, and it was a perfect marvel that the plant had survived. I sailed up the lovely Truro river, past Lord Falmouth's seat, through

woods where the trees except a few Larches were as bare of leaves as a barber's pole.

No spring here, then let me go further south yet; so I posted to the Lizard and stopped a couple of nights at the most southernly inn in England. But it was colder here than at Falmouth; the east wind followed one like an evil spirit, determined to rob you of all pleasure. But it could not do this quite here; the rock scenery of the Lizard coast was too grand and far too interesting for any amount of east wind to make that visit anything but a joy and delight. I suppose most of the readers of our Journal have seen the Lizard, but if perchance any who have not seen it are in doubt where to spend their holiday this autumn let me recommend them to go to the Lizard. There is capital accommodation at Miss Mundy's, the "Old Inn," at Mullion, and also at the Lizard Town or at Cadgwith, and a month might well be spent exploring the wonders of the coast. I shall never forget Kinance Cove and Asparagus Island. It is impossible to describe it, but the artist, the geologist, the botanist will alike find it a rich field for the pursuit of their favourite studies. The varied hues of the serpentine rocks of nearly every colour from white to the deepest red, dripping with water as the sea leaves them, and lighted up by the sun rays, appear like bright jewels that have been laved by the sea and kissed by the sun. It is indeed enchanted ground, and I wished I could have remained longer there; but my time was so limited that I had to push on to Penzance so as to see the Land's End, and stand on the most western point of Old England. I stayed the remainder of my time at Penzance, as there is so much to see there and such charming excursions can be made from it. The "Queen's Hotel," too, is such a capital place to stay at that one feels disinclined to leave it.

I think Mount's Bay the most lovely one in England. St. Michael's Mount from a distance appears to be much further out in the Bay than it really is, and with a dim haze over it, or a setting sun, the grand old rock which has over and over again been stormed, stands out like a gigantic sentinel keeping watch over the Bay that bears its name. Close to Penzance is the picturesque fishing town of Newlyn St. Peters; picturesque indeed it is with its narrow streets and its exterior staircases, but, oh! so dirty, and the odours! I cannot really understand how it is that a plague does not break out, for there literally is no drainage, the filth of each house is thrown outside the door, and you are literally poisoned as you walk through the streets.

There is also a remarkable man at Newlyn in the shape of a policeman. It is told of him that when the snow fell this winter the men of the place, delighted with the rare and unexpected visitor they had not seen for seven years, commenced snowballing, upon which the policeman, thinking it was a shame that he should be left out of the fun, set to work and joined in the fray. On another occasion a man was engaged in the favourite pursuit of chastising his wife. The latter naturally bellowed, and her female neighbours in sympathy went to bring the policeman. He came, he saw, but by no means did he conquer the brute—far from it: he turned round to the indignant spectators saying, "He did not like to be unneighbourly," and marched off declining to interfere. A friend told me this as an illustration of his dictum, "The laws of England cease to have effect when you cross the Tamar. We are here governed by public opinion."

The distance from Penzance to the Land's End is about ten miles, and a one-horse coach goes from the post office every morning. This is driven by a most amusing man, who tells you no end of anecdotes. The age that people attain to in that district is something wonderful. When the gentleman who built my place here asked the late Lord Bridport to sell some land for a churchyard, he replied, "What do you want a churchyard for? No one ever dies at Monkton Wyld." I wonder what he would have said if he had such lives on his copyholds as some of those in the Land's End district. You see that man mending the road; what age do you think he is now? Why he is eighty-six, and he does a hard day's work winter and summer. There are four generations of his family living together; but that's nothing round about here. We have five generations living together, and the best of it is they are all called Matthew. You'd think there would be some difficulty in distinguishing them, but there's not. The great grandfather, who is ninety-six years old, him they call old Matthew (and well they may), the next they call grandfather Matthew, his son is Matthew, the next young Matthew, and the last young Matthew's son Mattie.

On arriving near the Logan Rock the driver introduced me to an old guide, who turned out to be a most entertaining old fellow. "You see this little mead, sir, that reminds me of what occurred here when I was a buoy. Oh, sir! the depravity, the terrible wickedness of buoys. It's in their nature, it seems engrained in them like bee's wax. Well, sir, when I was a buoy about nine years old I was tending some geese, and an otter came out of a hole determined to have one of them geese, but I was determined, too, he should not. Now, I had no terrible amount of courage—I was not over bold—but I could swear, aye, swear terribly, and so I kept swearing at it and throwing stones. The otter kept following me, and I kept running across the meadow, swearing and picking up a stone and hitting him, and then bolting, till I made such a row that a man came up to see what it was about, and then shot the otter. But how I did swear; oh! the depravity of buoys."

Tol Prid Penwith is certainly the boldest headland I ever saw; but in my humble opinion the Land's End district will not compare with the Lizard. But here it was as cold as any other place, so I came home, having failed to find spring; but having enjoyed my visit to Cornwall more than I could have believed possible, seeing that the east wind never left me for an hour.—JOHN B. M. CAMM.

REGENT'S PARK.

THE beds continue to be exceedingly gay with Tulips. Being somewhat later than usual, these gay flowers pertain more to early summer than to spring, and, as Mr. Robson remarks, are apt to interfere with the summer-bedding plants; still there is no gainsaying their enlivening effect. Most of the beds are well filled. Several varieties are planted, but those which are the most effective may be limited to four distinct kinds—viz., Double Tournesol, very gay; Vermillion Brilliant, dazzling scarlet; Cottage Maid, lively rose; and Yellow Prince, bright and sweet. These varieties are clear, distinct, and free for bedding purposes, and, moreover, are inexpensive. Bedding-out is being carried out in full force—in fact, hundreds of Pelargoniums have been planted more than a week ago. The Chestnut Avenue will in a few days be very beautiful. The trees are richly laden with flowers just expanding, and the brightness and freshness of the foliage has not suffered from spring frosts.

EARLY WRITERS ON ENGLISH GARDENING.

No. 4.

GERVASE MARKHAM.

THE Markham family trace their pedigree to a period before the Norman Conquest.* Their Cotham estate, which is near Newark in Nottinghamshire, they acquired by marriage, and there Gervase Markham was born the third son of Robert, about the year 1568.

His ancestors had been too recklessly extravagant for his father to provide him an income, but he gave that best substitute—a good education, but he does not appear to have been to either University. Gervase was an excellent classical scholar, and well conversant with the French, Italian, and Spanish languages; moreover, he was wise as well as knowing, so having the best aids to success, "parts and poverty," he prospered in the world, and is one of the chief worthies of a family rich in clever men.

He was able to write marketably well in verse as well as prose, and I will first and at once notice his rhymed productions. In 1595 he published "The most honorable Tragedie of Sir Richard Grenville," an heroic poem. It is now so rare that, though of only ninety pages, Mr. Grenville a few years since gave nearly £41 for a copy. It has been reprinted recently. In the same year Markham published "The Poem of Poems," which is the Song of Solomon versified. In 1597 "Devereux," a lament translated from the French, the personages mourned for being Henry III. of France and Walter Devereux who fell at the siege of Roan. One of the rarest of booke is "Rhodomanths Infernall, or the Divell conquered; Ariosto's Conclusions, &c." Its author was Philip Des Portes, and this translation, published in 1598, is dedicated by G. M. to Lord Mounteagle.

He says the translation was "first intended for one privat

* Mr. Clements R. Markham, so favourably known as the Secretary of the Geographical Society, and as the author of several very useful literary works, had privately printed in 1854 "A History of the Markham Family." This had been written by his father, the Rev. D. F. Markham. To it and to the courtesy of Mr. C. R. Markham I am much indebted.

man's repast, and the translation was finisht and foorth of my hands above a dozen years agone, a time wherein bumbasted breeches and straight whalebon'd doublets had neither use nor estimation," fashions of France and Spain of which he was not the only satirist.

In 1600 he produced "Tears of the Beloved," and the year following "Marie Magdalene's Tears," two religious poems, recently republished with a memoir by the Rev. A. R. Grosart. In 1608 he translated "Ariosto's Satyres," and in the same year produced, in co-operation with Lewis Machin, "The Dumb Knight." It is a comedy, the plot taken chiefly from Baudello's novels, and the scene assumed to be the Isle of Cyprus. In 1609 he translated in verse from the Italian "The noble courtezan, Paulina;" and lastly, in 1622, the tragedy of "Herod and Antipas," founded on the narrative in Josephus's "Antiquities of the Jews."

In 1599 he published his first prose work that I have seen, "How to chuse, ride, traine, and diet both hunting horses and running horses, &c." It is dedicated to "his singular good father Ma. Robert Markham, of Cotham, in the countie of Nottingham, Esquire." In it he states he has here "gathered together my lives experience," and that "no man's aplaus can better please me," for his father was as fond of horses as himself, and it so fell out that Cotham, his chief manor, became the property of the Duke of Newcastle, who loved horses as well. The manor still belongs to the duke's descendants.

In 1595 was published "The Gentleman's Academie; or the Booke of St. Albans, containing three most exact and excellent Books—Hawking, Hunting, and Armorie, compiled by Juliana Barnes in 1486, now reduced into a better methode by G. M., and dedicated to the gentlemen of England, and all the good fellowship of Huntsmen and Falconers." Another edition was published in 1801. This, I have no doubt, was prepared by Gervase Markham.

I must do little more than record the names and dates of Markham's many books on the same subject. In 1616 appeared his "Methode or Epitome," detailing remedies for the diseases of all "animals and birds kept for profit." In the same year was published his "Cavalarice, or the English Horseman," in eight books, each dedicated to a different patron. Next came forth his "Master-Piece," of which I have only seen the fifth edition, dated 1636. In 1639 appeared his "Complete Farrier," which in the preface he announces as "the last of all my labours," and well it might, for his "Faithfull Farrier" had been published the year previously, yet he had signed its preface "Gervas Markham's last and best labours!" These had been withheld from the press by the publishers to whom he had sold them, and were not published until after his decease. They related to subjects on which he wrote with the authority of a master. So much were his writings on the subject in request, and so many books relative to the subject did he compose, that at last he agreed with their publishers to write no more! In consequence, probably, a work he wrote remained unpublished, and of which Mr. Clements R. Markham informs me he has the MS. It is entitled "Le Marescale, or the Horse Marshall, allso those secrets weh I practise but never imparted to any man." The agreement *not* to publish is as follows:—"Mem. That I Gervase Markham of London, gent., do promise hereafter never to write any more book or books to be printed of the diseases or cures of any cattle, horse, ox or cow, sheepe, swine, or goates. In witness whereof I have hereunto set my hand the 24th daie of July, 1617.—Gervase Markham."

This memorandum has been said to be in the archives of the Stationers' Company, but after repeated searches the courteous officials of the Company have not found it. They have found and copied for me the following entry, which shows that the publishers of those days had contentions about his published works:—"August, 1617. The Court issued an Order to settle the controversie between Roger Jackson and John Mariot for the printinge of the booke called Markham's 'Farewell to Horsemanshippe and Husbaudry.'"

"The perfect Horseman, or the experienced secrets of Mr. Markham's fifty years practice, now published by Lancelot Thetford, practitioner in the same art for the space of forty years," was published in 1655. The preface states that "Notwithstanding all Mr. Markham's promises in his former books to lay open his cabinet councels you shall here find many most rare secrets bequeathed as a legacy to his most intimate friend the publisher hereof." Prefixed to this volume is the portrait of Markham, of which an enlarged copy accompanies these notes.

During the years he was publishing those works he employed his pen and other publishers upon the recreations of rural life. "Country Contentments," relative to hunting, hawking, and housekeeping issued from the press in 1615. "Conceytted letters newly layde open," in 1618, which in modern phrase is "a polite letter writer." "Hungers prevention or the whole arte of fowling" in 1621; and "The Art of Archerie" in 1634.

I now come to the few works which entitle Markham to a place in these notes. The first was "Cheape and Good Husbandry." The fifth edition, the only one I have seen, appeared in 1631, and though including much that he had before published relative to animals, yet it includes new information relative to poultry and bees.

The next was much more original, but I do not know the date of its first publication. The copy before me is entitled, "The English Husbandman—1st part husbandly duties. 2nd, Planting, grafting, gardening, &c. Newly corrected, &c., by the first author, G. M. 1635." In the dedication to the Duke of Lenox he says, "When I was a servant to your noble ancestor, and had houres to bestow on my own studies, then at Layton, I first thought of this work." He ridicules those who translated from Virgil, Xenophon, Libault, and others, justly observing that their directions were for other climates. It is a really practical work, and shows that many of our varieties of fruits are more than two centuries old. For example, among early Apples are Jenitings—Wibourns—Pomederoys—Queene Apples. He details directions for raising stocks from kernels and stones, and those for grafting are good, and so are those for managing the fruit-room. He denounces the undervaluing of our English gardeners, and says, "I call into my remembrance that in all the forraine places I have seene there is none more worthy then our owne." The engravings of knots for the flower garden are many and original.

In 1620 he published "Farewell to Husbandry, or enrichment of barren grounds." In 1631 "Enrichment of the Weald of Kent," which especially recommends the employment of marl as a manure, and seems from the dedication to a Kentish land-proprietor to have been written especially at his instigation. In 1623 Markham had published an edition of "The Country Housewife's Garden," but I am not aware of the date of its first appearance. Of its contents it will suffice to quote, "In the month of Aprill the moone being new sow Marjoram; in the full of the moone Apples of Love."

Just after his death in 1638 a publisher combined the various cultural works of Markham, and published them under the title of "A way to get wealth, containing sixe principall vocations or callings, in which every good husband or housewife may lawfully imploy themselves." The sixth, however, "The making of Orchards," was by William Lawson.

The course of Markham's life was uneventful, being such as is the usual career of a man whose breadwinner is his pen. His knowledge of horses led to his being employed by James I. to obtain him an Arabian horse. Markham imported it from Constantinople, and obtained for it £500 from the King. It is not improbable that he owed his introduction to that monarch to his kinsman, and I believe elder brother, whose memorial stone in the south aisle of St. Mary's Church, Islington, has this inscription—"Here lyeth the body of John Markham, Esq., one of the Serjeants-at-Arms to our most gracious Sovereign King James, &c., who dyed the 26th of August, 1610.

> "He was both gentilke born and gentilke bred,
> And ere he dyed was well marryed
> Unto a vertuous and a loving wife,
> Who losing him loathed her life;
> Whose love hath built this for eternity,
> That he may still be had in memory."

Like his kinsman Gervas was also "well marryed." His wife was Anne, daughter of J. Gelsthorpe, Esq. They had no children.

On referring to the registers of burials at St. Giles's, Cripplegate, I found this entry—"1636. Jarvis Markham, gentleman, February 3." As the year then commenced in March, he was buried in the February of 1637 according to our present calendar. My reference to the registers was a consequence of a statement made in the Rev. Alexander Grosart's memorial that Colonel Chester had made a note that such a record was there. He rests among many more celebrated men, for Milton the poet, Fox the martyrologist, Frobisher the arctic navigator, Speed the topographer, and Dr. William Bulleyn, one of our earliest herbalists, are there interred.

That Markham died poor there can be no reasonable doubt.

He tells us, "Patience I have long since made mine owne and only companion," and there is no will of his or letters of administration to his estate recorded in the indexes at Somerset House.

The prefaces and dedications of his works afford satisfactory testimouy that he was an honest christian man, and this leads me to details of the doings of his namesake—doings that have wrongly been attributed to the snbject of these notes.

Gervase was a name adopted in each branch of the Markham family, and I have now before me records showing that besides Gervase Markham of Cotham, there were as his contemporaries Gervase Markham of Ketlesby in Lincolnshire, and Gervase Markham of Dunham in Nottinghamshire. This last-named was our author's cousin, and the earliest of whose turbulent actions of which I have seen a record was his challenging Lord Darcy of the North. This was in 1616. They had hunted together, and Markham struck a servant of his lordship, who threw him down. was upon him and striking him when Lord Darcy took off his man and reproved him, yet Markham chid Lord Darcy, who replied that if he had not taken his man away he would have beaten Markham to rags. Markham wrote five or six letters to Lord Darcy, subscribed them, but hoping to evade the law did not send them, but dispersed them unsealed in the fields, and they charged Lord Darcy with lying, concluding with the hint that if Lord Darcy wished to speak with Markham and send his boy, he would be well used. Lord Darcy sued Markham in the Star Chamber, where he was censured, and fined £500. Chief Justice Hobart said the letters were libellous, and though no direct challenge there were plain provocations to it, and though the offence was aggravated by the plaintiff being a peer of the realm, yet the sentence arose out of the nature of the offence, not out of the circumstances of the person, for causing death in a duel is murther. The Chief Justice records the sentence in his "Reports," adding he was resolved to punish all such as were guilty of "this damnable presumption." "This sentence of mine," he concludes, "it pleased the King (James I.) much to approve, and it pleased him to say that I did hit his own mind in it. This was the last day in December, 1616, when it pleased him to confer with his poor servant of divers things."

Fig. 90.—Gervase Markham.

In 1627 an information was laid that arms and horse accoutrements were concealed in the house of Gervase Markham, and Secretary Coke issued a warrant to search his house. The arms and accoutrements were found and seized; but Mr. Markham demanded that they should be either restored, or that he might have payment for the same, "considering that he justifieth himself comformable in religion." The Earl of Newcastle applied to the Council in 1629 that the arms, &c., should be restored; and to sustain the application it was certified that Gervase Markham was then bed-ridden, and had from his youth been a Protestant. A certificate also was enclosed from the Rev. Walter Carey, Vicar of Dunham, that Gervase Markham had for eleven years attended the Church, and had no imputation of papistry. Whether he inclined to the Roman Catholic adherents of the Queen's friends may be doubted; but there is no doubt that he favoured the high prerogative measures of the King.

In 1635 a conversation took place at Eagle Hall, Lincolnshire, relative to mustering forces for Charles the 1st, and it was casually observed that Gervase Markham, a kinsman of Thomas Markham, had one of the best horses shown at the Newark mustering.

Sir John Byron, Sheriff of Nottingham, reported in January, 1635–6, that Gervase Markham complained that he was charged excessively for stup money; but the Sheriff thought to the contrary. He was assessed at £50, in regard he was a single man, and had in land £800 a-year, and £40,000, reputed, out at use. He wrote very discourteonsly to the Sheriff, and it resulted in the Serjeant-at-Arms arresting him. Gervase was so infirm, and all his members so useless, that he could not be conveyed to London. It was proved that he had not been out of his chamber for five years, nor out of his bed for two years. Mr. Cary, Vicar of Dunham, again certified to the truth of this statement, and that he had received the Communion in bed many years. He was on his petition set at liberty in March of the same year. He died in January, 1636–7, just twelve months after his arrest, and was buried in the same vault with his father in Laneham Church.

There is a monument to their memory, with a figure of the father in his magisterial robes, and the son in armour with a love-lock descending from his head and fastened to his belt. The armour and the love-lock are symbolical, for he was courageous and amatory. He was an intimate friend of the Earl of Shrewsbury, and the gallant and champion of the Countess, in which chivalric capacity he tourneyed, and was seriously wounded; but he was nearly killed in a duel with Sir John Holles, relative to the killing of one of the Shrewsbury dependants, and probably these wouudings caused the decrepitude which I have noted afflicted him during the concluding years of his life.

During all the years of turbulent and decrepid life I have detailed, Gervase Markham the anthor was actively employed in writing and publishing a series of works on rural affairs, and the mere dates of their appearance are sufficient evidences that he could not be the offender.

CATASETUM MACULATUM.

This belongs to a genus of Orchids more remarkable for the characteristic formation of the flowers than for their ornamental appearance. Nearly all the species have dull purple

and greenish-yellow flowers. C. maculatum is green with purple spots; it succeeds well in an ordinary stove temperature, but requires a decided season of rest by being kept dry at the roots, and in a minimum temperature of 55°. The roots may require water occasionally during the resting period, but no more must be applied than will keep the pseudobulbs from shrivelling. C. maculatum is a very strong-growing species, and of easy culture, and requires rather more depth

Fig. 91.—Catasetum maculatum.

of compost than some Orchids that succeed best in pots. The pot should be filled to one-third of its depth with drainage. The best compost is equal parts of turfy peat and sphagnum; a few bits of charcoal may be added to sweeten the material when it begins to decay. A goodly supply of water is necessary during the growing season, with plenty of atmospheric moisture. When water is applied to the roots it is as well not to wet the pseudobulbs. Should it be hot and dry when the plant is in full growth, it will be benefited by being occasionally syringed overhead.

ROSES.

Roses portraited in Mr. Van Houtte's "Flore" are—1, Bernard Palissy; 2, Charles Lefebvre; 3, Madame Campbell d'Islay, or Triomphe de Valenciennes; 4, Empereur de Maroc;

5, Tricolore de Flandre; 6, General Washington; 7, John Hopper; 8, Gloire de Dijon. Nos. 2, 4, 5, 7, 8 need no appraiser or commentator. (*Vide* note, to which I especially call Mr. Van Houtte's attention, as he once said I was the most picturesque writer of the age!) No. 1 is one of the best of Julea Margottin's children: it is quite distinct; it is an expanded Rose, bombed and frilled like a shirt. I wonder why it went out? It is one of Margottin's masterpieces. I still retain it, but do not recommend it because it has gone out of the catalogues. No. 3 is, when it comes like a zebra, very fine, but usually it is a reluctant opener, like La Reine its parent. I still retain it. I have seen on the same twig a perfect La Reine and a perfect zebra. It is a sporting sport. No. 6 when it opens successfully is a grand Rose. It usually—almost universally—splits its petal band, and looks like a horseshoe. It is a hardy, fine-growing, bud-producing Rose. I gave away thirty fine plants of it for the above reason; still exhibitors should retain it.

Synonymes (Teas), 1, Belle de Bordeaux, or Gloire de Bordeaux; 2, Bougère, or Clotilde; 3, Clara Sylvain, or Lady Warrender, or Madame Bureau; 4, Madame Maurin, or Adèle Pradel, or Madame Denis; 5, Madame Bravy, or Alba rosea; 6, Souvenir d'un Ami, or Queen Victoria; 7, Céline Forestier, or Liesis; 8, Le Pactole, or Madame de Challonge; 9, Madame Desloregchamps, or Adelaide Pavie; 10, Narcisse, or Enfant de Lyon; 11, Catherine Guillot, or Michel Bonnet; 12, Louise Odier, or Madame de Stella; 13, Modèle de Perfection, or Céline Gonod; 14, Auguste Mie, or Madame Rival; 15, Le Lion des Combats, or Beauté Francaise; 16, Louise Peyronny, or Lælia; 17, Madame Masson, or Gloire de Chatillon. These, in my opinion, should not have gone out; I will buy either on their own roots—say twenty plants. 18, Maurice Bernardin, or Exposition de Brie, or Ferdinand de Lesseps, or Auguste Neumann (I see no difference here); 19, Sénateur Favre, or Puebla, or François Fontsine; 20, Sophie Coquerelle, or Julie de St. Aignant; 21, Virginal, or Madame Liaband; 22, Madame Campbell d'Islay, or Triomphe de Valenciennes. —W. F. Radclyffe.

[Mr. Radclyffe sent some specimens of his Roses to a brother rosarian, and the following are a part of his comments—"When I opened the box and spread the contents before me tears of envy almost came to my eyes—such clean, bright, handsome foliage, Felix Genero especially, and so healthy and vigorous too! Having seen leaves from your Rose trees I should like to have a leaf or two out of your book of successful Rose culture."—Eds.]

NORTHERN GARDEN PROSPECTS.

The season of 1874–5 has been as trying a one as many young gardeners will remember; and for the matter of that the veterans will have difficulty in recalling many seasons which have more sorely exercised their judgment and puzzled their skill. I speak of the north of England.

Commencing in October, we had high winds, sleet, rain, and frost, which continued until the beginning of December, when for nearly a month thick snow lay continuously on the ground, accompanied by frost of unusual intensity. Water pipes and gas pipes were frozen up, and both indoors and out the most unremitting and judicious care and attention was necessary to continue vitality in plant life; and despite the most vigilant care great numbers of plants fell victims to King Frost. On the evening of the first day of the new year rain fell copiously, rendering the hard-crusted snow like a sheet of glass. By-and-by the intensely cold atmosphere yielded to the successive days' rains, and was followed by as great a transition of warmth. Water pipes were burst in all directions, and much loss from this cause resulted. January continued mild throughout, and the hitherto torpid vegetation took precocious spring-like life. Fears were now entertained that this precocity would soon receive a withering rebuff; and so it happened, but not to the extent anticipated. During February and March a seasonable coldness prevailed, and the wind continued almost daily in the east. Thus was the immature growth of January checked, and we began to breathe more hopefully in anticipation of the spring months.

April was simply a glorious month. The earth, irrigated by the heavy falls of snow of December, heightened by the copious showers of January, and which was held *in statu quo* by the neutral months of February and March, yet retained great moisture, and consequently, although only about 1¾ inch of rain fell in April, vegetation made rapid progress, heavy nourishing dews falling nightly, a slight frost being perceptible on but one night, from the effects of which we soon recovered. Since the advent of May we have had slight showers, bright sunshiny days, and a daily temperature of 60° and upwards in the shade. But the call was that more rain was wanted, and it came. On Wednesday, the 5th a thunderstorm passed over, and on the evening of the 6th the earth was saturated with gently-falling rain, which continued through the night and up to noon of the 7th. At the present time we have ample reward for past anxiety.

Never do I remember such a wealth of blossom—not on one species of plant, but on all. The severe winter seems to have almost annihilated the living enemies of plant life, and the orchards and gardens, the conservatories and the fields are simply gorgeous in their wealth of bloom, whilst the change from blossom to fruit is being carried on under the most favourable auspices.

For several years past we have experienced severe frosts in the middle of May, and the recurrence of these is now our only fear. As an evidence of the early and favourable season we have an old couplet applicable to the north that

> "A swarm of bees in May
> Is worth a load of hay."

Swarms in the early part of May are held to be *raræ aves*, yet a local paper of the 6th inst. recorded no less than three as having taken wing on the 5th of May, one of which occurring in High Furness, Lonsdale North, is said to be the earliest ever known there in living man's recollection.—Beta.

THE TEMPLE GARDENS.

It is common to regard the great metropolis as composed of bricks, business, and smoke, from which vegetation is banished, and where the budding leaves of spring are not to be seen, yet within two minutes' walk of the busy thoroughfare of Fleet Street are forest trees of full size and healthy, and a few yards further is a smooth expanse of turf of refreshing verdure, and a display of flowers of enlivening aspect. This is in the gardens of the Inner Temple.

These gardens are renowned in the autumn for their displays of the Chrysanthemum, and are also gay in summer, and perhaps especially in spring by a glowing array of Tulips. The beds of Tulips have this season been especially fine, but the recent rains have accelerated the decay of the still bright petals. A border about 70 yards long of Rex Rubrorum is exceedingly rich, while large beds of the double Tournesol are massive and glowing. Beds of Keyzers-Kroon edged with white Pottebakker are very effective, but their beauty is on the wane. These are the only varieties which are grown in any quantity. Scarcely a blank is to be seen in the beds.

It is gratifying to see the encouragement given by the authorities to the cultivation of flowers in the heart of London, and the success which has attended Mr. Newton's efforts in creating a brilliant spring display on the north terrace is suggestive that the south terrace is equally adaptable to the same purpose, and would add a fine feature to the view from the Thames Embankment.

SNAILS AND FRUIT TREES.

How much damage is done to young fruit trees by snails is not easy to determine, but there is little doubt that it is more extensive than is generally appreciated. The power of injury to young trees by snails is immense, and I do not hesitate to say that more damage is done by the midnight feastings of these molluscs than by any other cause or means whatever. Young fruit trees are planted with every care that the work is well done. As spring approaches their bursting buds are watched for with interest; but the trees break stubbornly, and many buds seem to make no progress whatever. In nine cases out of ten the cause of this is the slugs and snails, and yet they are never suspected. The moment the buds swell are they seized by the snails, and damage is done before it is visible to the human eye, except by very close watching. But surely a gardener will watch? Well, he may; but how many amateurs are there who have planted trees to cover their walls, and who never suspect danger from this source? It is to these that the reminder is given—watch for the snails on your young trees. They will, if unmolested, ruin a tree in a single night by eating off the buds that were indispensable to form the future branches. Spread soot and lime along the wall, and, above all, examine the trees by candlelight. This is

one of the little matters of great importance pertaining to gardening pursuits, and is worthy of special attention at this period of the year.—W.

CALCEOLARIA FAILURES.

We have received from several correspondents complaints of the decay of their plants, both herbaceous varieties in pots and bedding plants intended for garden decoration. That failures in Calceolaria culture are extensive we have abundant evidence, and that the causes of these failures are to a certain extent enveloped in mystery we are ready to acknowledge. It must necessarily be so. It is not always easy for a gardener even who has devoted his life to the cultivation of plants, to describe their real state and to intelligibly convey to another precise data leading to a correct appreciation of the circumstances which exert an influence on the plant's condition. That being the case with the gardener, is in a still greater degree so with the amateur; and it is, therefore, less from the statements of others than by incidents of our own experience, that we seek to investigate common causes of failure, and if not to point out a remedy, at the least hope to aid in preventing a recurrence of the evils complained of.

In the case of herbaceous Calceolarias which decay round the collar just as the plants are coming into bloom we cannot prescribe a cure. For the origin of the evil or disease we should be inclined to look back for some months, and such a remedy as can be offered is only in time for future plants by advising a means to prevent the decay being originated in the plant's infancy. There is always a hope of an evil being preventible when it is, at will, producible. That the decay of herbaceous Calceolarias can be produced we have no doubt, and perhaps we cannot do better than give a familiar recipe for its production.

Sow the seed in any light soil, peat predominating. Do not pot-off the plants too soon, but allow them to become drawn in the seed-pan. Let them become dry occasionally until the leaves flag, so that the stem becomes somewhat hardened. Eventually pot them singly into small pots in sandy soil. Let the soil be put lightly into the pots, but press it firmly and neatly round the necks of the plants. As soon as the pots are filled with roots do not shift them, or, perhaps, they may not decay, but suffer them to become thoroughly pot-bound, to flag at times, and carry a few insects. If standing on ashes let them remain to root well through the bottom of the pots. When the foliage has turned yellow and the stems are woody, then proceed to put them in their blooming pots. The pots will lift with a large cake of roots at the bottom. As this cannot be drawn through the pot it must be torn off. In potting, as the plants are rather leggy, they must be put deep into the pots to make them look dwarf. They must have rich soil to make up for lost time, and to further encourage them they must be regularly sprinkled and be kept rather close. By regularly sprinkling the soil must be wet on the surface but dry beneath. Plants so treated may be depended on to decay at the collar just as they commence to bloom. To that practice, or some modification of it, is to be traced the decay of nine-tenths of dying Calceolarias, the remaining tenth succumbing to some injurious and untraceable matter in the soil.

The remedy or prevention is clear. The practice must be reversed. The plants must not be drawn in the seed-pan, they must have no check by want of water, must never be pot-bound, or be infested by insects. They must not root through the pots and have the feeders torn off, and must not be hurried in any part of their life to make-up for lost time. The effect is the same whether the rootlets are torn off or dried-off. The main roots may still look healthy, but their feeders are gone, and, unlike Geraniums or Fuchsias, Calceolarias will not emit fresh feeders at the summons of fresh soil and plenty of water. Instead of that the plants decay. A steady, regular, unchecked growth throughout; the soil richest at the bottom of the pots and never dry; a cool bottom on which to stand the plants, no matted roots through the pots, no fingering round the stems in potting, and healthy plants will follow. If, however, there is a suspicion that some fell agency is lurking in the soil, place crushed charcoal round the necks of the plants and have no fear of its effects.

As a general rule it is not insects or a poisoned atmosphere, nor yet a (normalty) poisoned soil that causes decay, but some little mistake at a critical time in a point of culture that is the real source of the evil. To meet the inquiries of several correspondents we have stated fully the results of our own practice in endeavouring to produce as well as to prevent this troublesome disease. We will notice the failures in the shrubby section on a future occasion.

AURICULAS.

As Auriculas are once more occupying a prominent place in the affections of florists, your readers may care to have some notes of the Show of the National Auricula Association held in Manchester on the 27th of April. I went over from Ireland, expecting to see great things in that, the classic ground of Auricula culture, and certainly I saw a fine display of plants. The entries seemed to me to be very numerous; and the effect of so large a number *en masse* was very cheering to a lover of this delightful flower. The Rev. F. D. Horner, the indefatigable Secretary of the Association, showed a very beautiful grey edge, called Alexander Meiklejohn, which took the premier prize in its class, beating George Lightbody. I, however, do not think it excels that perfect variety. I am apprehensive that it may have a weak stem, but I cannot be certain, as the plant was small and young. Mr. Horner also exhibited an extraordinarily large-flowered plant of Robert Traill, one of the best Auriculas ever raised, but generally rather small in the pip. Mr. Charles Turner showed some very beautiful and well-grown flowers. I much admired his C. J. Perry. It is a blue self, possessing that estimable quality, a satin-like surface, like a Pansy.

But I am not intending to laud exhibitors who are too well known to require it. I will just mention one or two points which struck me, and which may be worth thinking over against the next show. In the first place the exhibition should never have been held where it was. The Town Hall, though a splendid room, was altogether too dark. Plants on the side of the room away from the windows had no justice at all. Surely the Botanical Society of such a city as Manchester, in connection with whose Show the Auricula Association held theirs, could afford a large marquee, the only place in which flowers look to most advantage. In the next place, the space allotted to the Auriculas was too limited. They looked huddled up, and it was nearly impossible to make out what plants belonged to any one exhibitor.

I think also that the minimum number of pips might well be increased from three to five. Three pips may satisfy a judge as regards correctness of marking; but I submit with all deference that a good truss which is able to balance well luxuriant foliage is a very important point. The large number of three-pipped plants necessarily produced a lean and hungry look; and in many instances you could see that the pips had been purposely reduced to three.

I venture also to suggest a relaxation of that rigid rule which some of the old growers observed, and which seems to have considerably swayed the exhibitors, which demands as black a ground as possible in the edged varieties. Almost all the entries for the premium in the three classes of edged flowers had black grounds, and that produced tameness and monotony. We should strive to obtain every shade of colour that is possible into the edged varieties, and I am sure the Auricula would be much more popular. One of the most striking flowers in the Show was a Colonel Champneys, with rich violet ground and grey edge, and yet I am sure it would not have been able to compete for the premium with a black ground variety. I am glad I saw the Show; and all lovers of the Auricula are indebted to the National Auricula Association for what they are doing for our favourites. I hope the Association may prosper and improve in every respect each succeeding year.—Frederick Tymons, *Clk., Co. Dublin.*

CUTTINGS OF PLANTS SENT BY POST.

I observe in your advertisement pages that cuttings of plants of various kinds are forwarded to every part of the United Kingdom continuously by post. Accordingly I sent lately a few cuttings of Geraniums, securely placed in a small pasteboard box, postage duly paid, to a relation. To my surprise I received from the General Post Office, London, a printed notice to the effect that the box was detained by the authorities, "cuttings of plants" not being allowed to pass through the post, being amongst the "prohibited articles."

I replied to the notice, which was signed by G. Tilley, Esq., the Secretary of the General Post Office, requesting him either to forward my box to its destination or return it to me, with the postage paid thereon, as I did not consider "cuttings of plants" to come under the head of "prohibited articles;"

for not only these but vegetables were sent daily through the post. I received in answer to my remonstrance a second printed circular from the Secretary, which I will now quote verbatim:—

"If, as you allege, packets containing plants and vegetables do pass safely through the post, it can only be when they are accidentally overlooked; for if the nature of their contents were discovered they would at once be stopped. Your packet is still detained in the returned letter office; but it will be given up to anyone you may instruct to apply there personally for it." Query, Are Geraniums vegetables—or any kind of flowers?—WILLIAM MORGAN, *The Brewery, High Street, Pembroke Dock, South Wales.*

[Geraniums and flowers certainly are included in the comprehensive term "vegetables." The reason for prohibiting them must be that if succulent and crushed by the official punches the sap exuded might injure other letters. If enclosed in a box and sent by parcel post we think there would be no objection made by the post-office officials.—EDS.]

NOTES AND GLEANINGS.

OWING to the backwardness of the flowers this season the CRYSTAL PALACE ROSE SHOW will be held on the 26th of June instead of the 19th.

—— THE NOTTINGHAM AND MIDLAND COUNTIES ROSE SHOW AND HORTICULTURAL EXHIBITION will be held from the 8th to the 10th of July, both days inclusive. The prizes offered are liberal, and the Nottingham Arboretum in which the Show is to be held is of itself worthy of a visit.

—— THE NEW WINTER GARDENS AND NURSERIES in the Great Western Road, Glasgow, laid-out by Messrs. J. & R. Thyne, were opened on the 1st inst., when a floral and musical gala was held in the new grounds, which were crowded with several thousands of ladies and gentlemen. Refreshments were provided by Messrs. Thyne for their visitors, and the band of the 1st Royal Dragoons were present. An address was delivered by Sheriff Clark in the absence of the Lord Provost. The Gardens and Nurseries are on the Kelvinside estate, and from the commanding terrace on which the principal houses are situated a magnificent view is had of the Campsie and Dumbartonshire hills, while in the immediate foreground is a beautiful artificial loch, which, by-and-by, will be planted. The general plan of the Gardens is similar to that of Messrs. Veitch's establishment in Chelsea. The frontage is to a new road leading from the Great Western to the Patrick Road, and extends for 300 feet, while the space on which various glass houses are erected covers also nearly 300 feet. From the roadway backwards 25 feet is a terrace with a rise of 25 feet, planted effectively with Limes, Elms, Poplars, and the choicer Coniferæ. A broad avenue of Coniferous trees divides the Gardens into equal portions. Facing the west and parallel with the roadway are two conservatories, each 60 feet in length, one for stove and the other for greenhouse plants. At right angles to the conservatories are the Heath and show houses, each 60 feet long, with glass pits of a corresponding length with the houses, and forming as it were aisles to the main buildings. Parallel with the conservatories are six ranges of houses for propagating and forcing purposes, while the right and left of the whole establishment are occupied by a large Azalea house and a cool fernery, the latter especially being charmingly laid out.

—— IT is reported that an Italian professor has discovered that PERFUMES FROM FLOWERS have a chemical effect on the atmosphere, converting its oxygen into ozone, and thus increasing its health-imparting power. As the result of his researches, he states that the essences of Cherry, Laurel, Lavender, Mint, Juniper, Melons, Fennel, and Bergamot are among those which develope the largest quantities of ozone, while Anise and Thyme develope it in a less degree. Flowers destitute of perfume have no such effect. He recommends that dwellers in marshy localities and near places infected with animal emanations should surround their homes with a profusion of the most odoriferous flowers.

—— THE death of the well-known head of the great Ipswich implement manufacturers took place at Ipswich on April 29th. JAMES ALLEN RANSOME was born at Yarmouth in July, 1806, but the county of Norfolk has little claim on him beyond that of mere birthright. So early as 1809 he removed with his father's family to Ipswich. He was buried on the 3rd inst., and not only did the civic authorities but full 15,000 of his fellow townsmen attended the interment.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

THIS ought to be a busy time in this department, because from the genial nature of the weather everything grows very fast. It ought to be the aim of everyone to look well after all crops by hoeing and earthing them frequently. This not only benefits the crops, but it destroys the progress of weeds, which come up by thousands, and if not checked would impoverish the soil to the detriment of any crop for the whole season. An excellent Scotch gardener from whom I received my first lessons in gardening always said, "Hoe every inch of ground whether you see a weed or not, for depend upon it there are generally hundreds ready to spring up at the first shower, though they may not be visible at the time of hoeing." Unless it is done in this way we may be constantly at the work, therefore it is easy to see that in a simple matter like hoeing it is necessary to do it well.

Thinning Crops.—This is also an important matter in gardening, and should be attended to opportunely and with judgment. Everything needs sufficient space to develope itself or the crop is not satisfactory, therefore do not delay thinning. Onions, for instance, which make an abundance of roots though the top is small, should be thinned early, though it may be done at two or three different times, otherwise those that are left are much interfered with and checked by the operation. Carrots, Turnips, Spinach, Parsnips, and many other vegetables come under this rule. If time can be afforded it will pay to prick out plants of the Cabbage tribe on a border of good workable soil. Such plants generally become stouter and better developed by the operation, though in large gardens they are frequently planted out from the seed bed simply because other work presses so much.

Sow the main crop of Scarlet Runners. This vegetable is the most profitable of any for a town garden, provided it is allowed a rich soil and plenty of water while growing. It will thrive almost anywhere. A courtyard, even if all walled-in, will afford a place for this vegetable; and even though it requires tall sticks for its support when grown out in the open ground, yet as these are not easy to obtain in many towns, and moreover are expensive, the Scarlet Runner will thrive against a wall and look also ornamental. The plan sometimes adopted is to drive nails at equal distances, say 8 inches apart, both along the top and bottom of the wall, and then connect them together with twine; this affords sufficient support to the plants which grow rapidly.

Keep up successional sowings of Peas, Broad Beans, and Turnips as well as Cauliflowers for a late crop. Another small sowing of White and Purple Cape Broccoli and the main crop of Purple Sprouting should now be sown. Most of the spring Greens must be sown at once, such as Tall and Dwarf Green Curled Kale. Scotch Cabbaging, Buda and Ragged Jack Kales must also be sown, and a successional sowing of Drumhead and Green Curled Savoy. Lettuces, too, must not be forgotten; it is as well to sow these thinly in rows where they are to stand, as they do not transplant well in dry hot weather. Earth-up Cauliflowers, and if the weather should set in dry they will need mulching and also an abundance of water. Those who grow Tomatoes may safely trust them out now if the plants are strong and have been well hardened off. They, too, like a rich and deep soil to grow them well. Places should be specially prepared for them, and during growth they should be as systematically trained and stopped as a Grape Vine.

Prepare places for Vegetable Marrows. The plants will need a temporary protection at night for a short time after being put out. This is a useful vegetable and generally does well in town gardens, and will accommodate itself to any half-rotten heap of rubbish to grow in, but they must never be allowed to suffer from want of water.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

APRIL, which is proverbially showery, was one of the driest months we have experienced. May has also brought bright weather, yet with some refreshing rains. On the first day of the month, the opening day of the Alexandra Palace, about half an inch fell, and Saturday last was almost a rainy day in the metropolitan district; no growing crops, therefore, suffer for lack of moisture at the roots. In a few days the earliest-sown Peas will be in full blossom, and they look strong and healthy. A second sowing is coming on rapidly; and the third, which comprises G. F. Wilson, Fillbasket, and Veitch's Perfection for succession, has had the wire guards removed, the ground between the rows hoed, the rows earthed-up, and sticks placed to them. Another sowing has been made; this time Round or

summer Spinach has been sown between the rows. A second sowing of Windsor Beans has been hoed and the rows earthed-up. We have watered the earliest Cauliflower plants and hoed later crops; indeed, we keep the hoe at work as much as possible, as, if the weeds are well kept down now, there is little trouble with them afterwards. We are now cutting Asparagus. This work must not be done in a careless manner; the heads must be cut before they begin to open, and the knife should be thrust down close to the head to be cut, so that those heads coming up may not be injured; it is usually cut about 3 or 4 inches under ground. Weeds came up numerously on the beds, and it has been necessary to hoe them.

A sowing of Cauliflower may now be made for the autumn crop. Veitch's Autumn Giant and Walcheren are the two best sorts. Broccoli may also be sown. Atkins's Matchless Cabbage, if planted out now from the beds, will form nice heads for cutting from in the early autumn months. Another sowing may be made to succeed them. Hoe and thin Carrots, Onions, and all growing root crops as soon as they are ready. The hoe cannot be too much at work amongst them, and much injury is caused by allowing the crops to grow too thickly together. The late Carrots, Parsnips, Beet, &c., may be thinned-out at once to the distance they are intended to be—Carrots and Beet 5 or 6 inches apart, Parsnips 8 or 9 inches from plant to plant. A few rows of the French Forcing or Early Horn Carrot should be only partially thinned, the remainder may be thinned-out as required for the kitchen. Cardoons may now be sown in trenches prepared as for Celery; the soil in which the seeds are sown ought to be light and rich. The seeds may be planted about 2 inches apart; it is as well to have plenty of plants, and this will allow of a goodly number to be thinned out; 9 inches is a good distance between the plants.

Vegetable Marrows and Cucumbers for pickling may be sown now on ridges under handlights. In the neighbourhood of London waggonloads of Cucumbers are produced without the aid of glass in any form, but if handlights can be used the crops are more certain. Turnips sown now will come in ready for use in July. Sow when the ground is moist; freshly-dug ground is best. Celery may yet be sown for a very late crop. Early-sown plants are now ready for pricking out; it is best to do this when the plants are small; plant on light but not rich ground. Our earliest sowing of Scarlet Runners and Dwarf Kidney Beans are through the ground. The present is a good time to make another sowing, as the first may be cut off by frost.

FRUIT AND FORCING HOUSES.

Pineries.—The young plants in succession houses should have careful attention, as any serious check to the plants in the early stages of their growth cannot be remedied by subsequent attention. It is not easy to do everything just at the right time at this season of the year, and all available house room is required for forcing purposes. Pine pits are too often used for forcing all sorts of crops—Dwarf Kidney Beans, Strawberries, Grapes, &c., and many gardeners fancy that Pine plants may be crowded closely together without injury to the ultimate welfare of the plants. Now, we strenuously dissuade from overcrowding at any stage; rather grow a dozen plants well than grow twenty-five in the same space which would give no satisfaction. In the next place repot the plants before the roots are matted round the sides and amongst the crocks at the bottom of the pot. The pot should be fairly filled with roots before repotting. When the plants are potted a bottom heat of 90° ought to be kept up, or even if the temperature of the bed rises to 100° no harm will befall the plants, as the roots are not close to the sides of the pot after repotting. If the temperature of the bed has fallen too low, and, as is not unfrequently the case, there are no pipes for bottom heat, the tan or decaying oak leaves must be turned over and some fresh material be added. Oak leaves make the best bed for Pine plants.

In the fruiting house where the fruits are in various stages of development it is dangerous practice to interfere with the beds, and those who have not the advantage of hot-water pipes underneath the bed labour under much more difficult circumstances than those who have. If it is necessary to turn the bed to increase the bottom heat, the plants receive a check by being too cool at the roots for a day or two, then the temperature may rise to 120°, which may do even more harm in the opposite direction. We can easily keep up the heat of our beds to 85° or 90° without disturbing the plants. The minimum temperature in any of the houses may be 70°, and may rise to 90° after the house is shut up in the afternoon; plenty of atmospheric moisture is necessary with the above temperatures.

Peach Houses.—In houses where the fruit is approaching the stoning period the fruit should have a final thinning. Many good growers make the last thinning after the fruit is stoned, and even then they allow a few to be picked off during the second swelling. If the trees are in good health the fruit will not drop off, and to allow it to remain during the trying period of stoning is merely to allow it to take the nourishment away from the fruits that ought to come to maturity. To have good Peaches the fruit must be thinned to at least a foot apart; Nectarines to 9 or 10 inches. If trees are weakly and have been overcropped the previous season, the fruit ought to be thinned-out even more than this. No more growths ought to be allowed on the trees than are required to bear fruit the following season. Syringe the trees with a garden engine night and morning if the house is large; small houses may be managed with an ordinary syringe. The border should be surfaced with manure, but no manure water ought to be applied to the roots. If any of the leaves are seen to curl up it is caused by the Peach aphis, and nothing destroys it so well as fumigating with tobacco smoke.

PLANT STOVES AND ORCHID HOUSES.

The occupants of these structures are now, if in a healthy condition, making vigorous growth. Many species of Orchids are just starting into growth, and at that time they throw out plenty of fresh young rootlets at the base of the growth: if any such require repotting, now is a good time to do it. We have repotted all the plants in the cool house that could be done without injuring the flower spikes. Odontoglossums, such as O. crispum, O. triumphans, O. gloriosum, and indeed all the cool section, have been repotted. We take care not to give them a very large shift, and any plants that were not making strong growths and had not quite filled their pots with roots, were placed in pots the same size as they had been previously.

Goodyeras and Anæctochilus have been repotted. This fine class of "foliage plants" have not been much seen in public recently, and in few places are they found in healthy condition. They succeed very well in our Cucumber house, grown in an ordinary handlight and shaded by the Cucumbers overhead. The pots are filled quite three parts full of drainage, and the compost is equal parts of turfy peat, sphagnum moss, and potsherds. Repotted Anthurium Scherzerianum. This is a splendid plant; it is easily grown, and now to be obtained at a cheap rate. It requires similar treatment to Cattleyas: fill the pots quite half full of drainage, over the crocks place some fresh sphagnum, and fill up round the roots with Orchid peat mixed with sphagnum and crocks; the plant should be raised up in the centre of the pot. When the plants are in full growth syringe them with clear rain water; syringing overhead does not injure the flowers.

FLOWER GARDEN.

The bedding plants are nearly all ready to be planted out, and if the weather continues mild we shall have some of them out before this is in print. Calceolarias and Zonal Pelargoniums will not be injured by any frosts we are likely to have now. It ought to be stated that our plants are hardy from exposure, and the plants are large. This is a busy time with the florist. Pinks, Carnations, and Picotees require sticks to be placed to them, and to see that they are free from green fly. Auriculas must have the decaying flowers removed, as they are unsightly, and seed pods may exhaust the plants.

Preparations must also be made to repot the plants. Clean pots of the sizes required and suitable mould must be in readiness. Some of ours have been repotted, and the remainder will be done in the course of a week or two. If repotted now the plants have time to make their growth before the sultry days of July and August. All the plants are now in a north aspect, and aired freely night and day; in fine weather the lights are entirely removed. Pansies will well repay any care that has been taken of them during the winter. If the beds were not mulched two months ago, a dressing of rotted manure ought to be applied at once, and the plants delight in plentiful supplies of water. Cow manure is the best stimulant for Pansies. Tulips are now coming into bloom, and those who are so fortunate as to possess choice sorts will see that they are shaded during the hottest part of the day. To enjoy them thoroughly they ought to be in beds protected by a canvas tent.—J. Douglas.

TRADE CATALOGUES RECEIVED.

Dick Radclyffe & Co., 129, High Holborn, London.—*Catalogue of Plants and Garden Requisites.*

Thomas Bunyard & Sons, Maidstone and Ashford, Kent.—*Select List of Bedding-out Plants.*

John Harrison, Darlington.—*Catalogue of New Roses, Clematises, and Bedding Plants.*

T. Simpson, Preston Road Nursery, Yeovil, Somerset.—*Catalogue of Bedding Plants.*

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Blackburn.—May 17th, 18th, and 19th. Mr. W. Ditchfield, Hon. Sec.

Crystal Palace Company.—Flower Show, May 29th; Rose Show, June 26th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.

Coventry.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.

Leeds.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.

BURTON-UPON-TRENT.—June 16th. Mr. Wm. Shave, Bond Street, Sec.
JERSEY.—Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.
GLASGOW.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.
FAREHAM.—June 23rd. Mr. H Smith, Sec. [Hon. Sec.
EXETER (Rose Show).—June 25th. Mr. J. N. Gray, Queen Street Chambers,
REIGATE (Rose).—June 26th, 1875. Bushby Britten, Esq., Hon. Sec.
WISBEACH.—June 30th. Mr. C. Parker, Hon. Sec.
MAIDSTONE.—(Roses), June 30th, at Vinters Park. H. Benstead, Esq., Hon Sec., Rose Club, Mill Street, Maidstone.
BIRMINGHAM.—July 1st, 2nd, 3rd, and 5th. Mr. Quilter, Aston Park Sec.
SPALDING.—July 1st and 2nd. Mr. G. F. Barrell, Hon. Sec.
SOUTHGATE.—July 3rd. John Miles, Esq, Hon.-Sec., Southgate, N.
DURHAM AND NORTHUMBERLAND.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.
GRANTHAM.—July 7th and 8th. Schedules, &c., from Mr. Lyne, Bookseller.
FROME (Rose).—July 8th. Mr. A. R. Baily, Hon.-Sec.
KILSBY.—July 8th. Sec., Mr. C. E. Bracebridge.
NOTTINGHAM.—Rose Show, &c., July 8th, 9th and 10th. Apply to Alfred Kirk, Municipal Offices, Nottingham.
OXFORD (Roses).—July 9th. Mr. C. R. Ridley, Hon.-Sec.
HEWORTH.—July 14th. Mr. R. H. Feltoe, Heworth, York, Hon.-Sec.
OUNDLE.—July 14th. Mr. Alfred King, Sec.

It will gratify a large circle of our readers to know that the new Judge who has been appointed to succeed Mr. Justice Huddleston in the Court of Common Pleas is the son of the late Dr. Lindley, Professor of Botany in University College, editor of the *Gardeners' Chronicle*, and so long connected with the Horticultural Society. Mr. N. Lindley, Q.C., was one of the leaders in Vice-Chancellor Hall's Court, and is author of a "Treatise on the Law of Partnership."

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*C. W. Milne*).—"London's Encyclopædia of Trees and Shrubs" will give you most of the information you need. (*R. H. Walters*).—Our "Flower Garden" Manual, you can have it free by post if you enclose five postage stamps with your address.

MILDEW ON VINES (*G. H.*).—Write to the preparer of the composition for information.

VINE LEAVES BLISTERED (*J. A. P.*).—The appearance of the leaves has nothing to do with insects of any kind. If the air of the house has been kept strongly heated and moist, and then a cold current of air admitted over the leaves, it has checked their expansion and produced the blistered appearance.

VINE LEAVES SCALDED (*A. A. and X. Y. Z.*).—The leaves are scalded, and the scalding is occasioned by bright sunshine on them whilst wet. Early ventilation and shading until the leaves are dried by it will keep them from being scalded.

WHITE PARSLEY.—"*Sigma*" would be glad to know what is the white Parsley used by chemists to flavour essences.

VIOLA MONTANA (*Puzzled*).—It is a hardy perennial; flowers light blue and scentless. It is propagated and cultivated the same as the common Violet. As you have signed no agreement, and we know none of the circumstances, we cannot give an opinion upon whether your landlord can turn you out summarily. If he can you have no right to claim the future fruit. We never recommended boiled oil to be used with red lead to thwart mice. The oil would tempt them to eat the peas.

ARRANGEMENT OF FLOWERS (*A. W. B.*).—We never undertake to arrange the flowers in beds and borders. We only criticise proposed arrangements.

CALCEOLARIAS DECAYING (*C. W. S.*).—The decay is caused either by some pernicious influence of the soil, or is the result of some check which the plants received in their early stages of growth. See what is said in another column.

SEEDLING PANSY (*R. Maries*).—It is a very fine specimen of the purple and yellow class. The purple is rich, and the size and substance of the large flower superior.

SHRUBS *versus* RABBITS (*A Continental Reader*).—There are very few rabbit-proof shrubs. When driven by hunger in severe weather these animals will eat almost anything of a vegetable nature; even Onions we have known them to attack. From observations in a rabbit-infested district, where trees of many kinds were planted twenty years ago, those only which have really escaped the rabbits are Rhododendrons. We believe this to be the best of all evergreen shrubs for planting where these animals abound. We should be glad to hear the opinions of others as to whether this immunity was accidental or whether Rhododendrons are really, in all districts, invulnerable to rabbit attacks. It would settle a point of importance, for if affirmative proof is given, of which we are sanguine, additional value would be given to this valuable evergreen. Mr. Abbey says, in another column, that the Corsican Pine (Pinus Laricio) is rabbit-proof, which is very welcome information. He has also, on page 352, vol. xviii., fully treated on the subject, and has given the following list of trees and shrubs which are not commonly interfered with:—Alder and Birch which on swampy ground it may not have been possible to approach, Hornbeam, and Wych Elm, English and Norway Maple, Turkey Oak, Willow, Wellingtonia gigantea, Cedrus Deodara, C. Libani, and C. atlantica; Cupressus Lawsoniana, Thuja Lobbii, American Arbor-Vitæ, Thujopsis borealis, Portugal Laurel, Juniperus communis, Pinus Cembra, Pinus excelsa, Lilacs, Gorse single and double; Ribes, none doing better than the Black Currant in strong soil or damp ground; Azalea, common Berberry, Gueldor Rose, Dogwood, Snowberry, Hazel, Sweet Briar, Blackthorn, Cotoneaster microphylla, Weigela, Spiræa, Rhus Cotinus, Rhus typhina, Canadian Gooseberry, Ribes album, Bird Cherry, Butcher's Broom, Spurge Laurel, Euonymus, Deutzia scabra, St. John's Wort, and Elder. We shall be glad to hear from other observers of any trees or shrubs of which they have proof that rabbits will not nibble.

VIOLETS (*Hamlet*).—The varieties of Violets to which you allude are in private gardens, but a majority of those named may be had of most of the principal London and provincial florists. The Double White is best propagated from rooted suckers or layers, and it may be done now in loamy soil, enriched with leaf soil or well-rotted manure, choosing a border shaded from mid-day sun, a north or east border answering well. Plant in rows 9 inches apart every way, and by omitting every fifth row you will have access to the plants. They should be well watered at planting and during dry weather, keeping off all runners and weeds. At the end of September the plants, or a part of them, may be taken up with balls, and be placed in a cold frame, having air freely in mild weather; a portion may be potted in 6-inch pots, and be kept plunged in ashes in a cold frame for about six weeks, when they may be removed to a light airy position in a greenhouse.

HARDINESS OF DRACÆNAS (*South of Ireland*).—The New Zealand Dracænas would not, we fear, succeed outdoors in the south of Ireland, though it is probable they would in warm positions and with protection. We should be obliged if those who have tried them would state the result.

TROPÆOLUM TRICOLORUM AFTER FLOWERING (*A Constant Subscriber*).—When the flowering is past assign the plant a light airy position, and keep it rather sparingly supplied with water after the leaves begin to turn pale, gradually reducing the supply, and leave off altogether when the foliage is quite yellow. The tubers may then be removed from the soil and placed in dry sand, and be kept in a cool place until the beginning of September, when they should be potted. They need only have the tubers covered with the sand, for when deeply covered they sometimes make shoots several inches long before potting, and which are easily broken. They should be potted before the shoots are an inch long.

ROSES ON THE MANETTI STOCK (*A. Beechey*).—They succeed admirably in soils which are not suited to the Briar, and require in a light soil liberal treatment. They should be planted so that the junction of the graft or bud with the stock is covered 2 to 3 inches deep. The best manure for a light soil is cow dung, but well-rotted stable or farmyard manure answers well. Water freely at the roots and overhead during dry weather, sprinkling a handful of guano in a space of about 18 inches around each plant, and wash it in with the water. This may be done early in May and every month up to September. The roots should have a mulching of manure in December. Prune in February if the weather is mild, shortening the strong shoots to five or six eyes, those moderately strong to three or four, medium growths to two or three, and the weaker spray to one or two eyes. The best liquid manure is guano, 1 oz. to a gallon of water.

TREATMENT OF VINES (*Richard Watson*).—The Vines ought to give you a good return; in fact, they should with ordinary treatment be worth £1 per Vine, but as you lack experience we advise you to make yourself acquainted with some work upon the subject. Our "Vine Manual" would give you the required information. It may be had by post from our office for 2s. 7½*d.* Where they are showing two and four shoots on each spur, remove all but one, or if the spurs are wide apart—you may leave two, selecting the best and most fruit-promising. If no fruit shows leave the lowest shoot. Stop the growth at one joint beyond the bunch, and if no fruit shows pinch at the sixth leaf. The laterals to be stopped to one leaf continuously throughout the season.

TREATMENT OF VINES AFTER INARCHING (*B. B.*).—Leave a few shoots upon the stock and above the junction so as to draw the sap past it, and when the union is complete, as it will be in about six weeks, gradually remove the shoots above the junction, and by degrees remove them altogether, as you may be justified in doing by the growth of the scion. It will grow very freely after the union is complete, and may then be detached, or you may cut it half through at first, and in a week cut through the other half. You may not have any fruit upon the Vine which you use as a stock, but if any show upon the scion you may take a bunch or two; and yet it is more desirable to secure a strong cane without fruit than to have fruit and a weak cane.

SHADING ROSE HOUSE (*Idem*).—There is no good in shading a Rose house employed for cutting, as the Roses will be out so soon as they expand. The only object in shading such a house is to prolong the bloom, but Roses do not like gloom or shade, and unless the shading be very light, and only used in bright weather, it will interfere with the ripening of the wood and the future flowering. Manetti stocks may be grafted outdoors in February or March, or even now if you have any scions with the eyes in a dormant state.

SHEEP BARKING FRUIT TREES (*D. W.*).—The cleanest, neatest, and most permanent mode of prevention is to tie thin strips of wood or old building laths round the stems, first putting round a strip of hay to prevent abrasion of the bark, and tie with rough-tarred yarn. Dressings of lime, &c., are, if not washed off by the rains, rubbed off by the sheep in dry weather.

SEAKALE RUNNING TO SEED (*A Young Gardener*).—You have no cause for fear. Let the plants grow until near flowering and then take off the flower heads, leaving all the leaves you can on the stems. Eyes for future crowns will form at the base which, if thinned out when an inch or two long, will perfect crowns for forcing next winter. If the base growth is weakly encourage with liquid manure. The unopened flower heads are excellent when cooked.

PLANTS FOR SPRING BEDDING (*R D.*).—Two months is a long time for plants of this class to be in full beauty. Some of the most useful plants for the purpose you name are Alyssum saxatile compactum, yellow; Arabis mollis variegata, which is effective from its variegation and sheet of white flowers; Aubrietia Campbellii, blue; A. græca, blue; Bellis aucubæfolia, finely-netted golden-variegated leaves and red flowers; the double red, white, and pink Daisies (which you have); Cerastium tomentosum, white foliage and white flowers; Cheiranthus Marshalli, yellow; Pyrethrum Golden Feather for its golden foliage; the variegated Thymes, both T. citriodorus aureus and T. aureus marginatus; Iberis gibraltarica, white; the Primula acaulis varieties, the double crimson, white, lilac, and yellow; Myosotis dissitiflora, blue; M. sylvatica, blue. Reds are not easily had, the best are Silene pen-

duls, pink; and Saponaria calabrica, pink. Violas and Pansies perform an important part in spring gardening, especially Violas, Blue Bell, it is of dwarf compact habit, an early flowerer, violet shaded with blue, yellow eye; V. cornuta Imperial Blue Perfection, violet blue, dwarf, and free; V. lutea major, golden yellow, early, and very good; V. Golden Perpetual, is very profuse blooming, bright clear yellow; V. Corisande is also free blooming, and a pale primrose colour; the best white is V. cornuta alba. Pansies suitable for the purpose are the well-known Cliveden Blue, Purple, White, and Yellow; and others are Imperial Blue, deep blue, one of the very best; Dean's White Bedder, early and one of the best; Bedfont Yellow, early and free; Blue King, light blue, free blooming and very effective. All are best raised from cuttings, which bloom more freely and earlier, not growing so vigorously as seedling plants; exceptions are Pyrethrum Golden Feather, Silene, and Saponaria, which are best raised from seed, the two latter being hardy annuals. The propagation and culture of all these would take up more time and space than we can devote to the subject. We shall be glad, however, to render you assistance if you are in any difficulty.

Evergreen Shrub for Wall (*Idem*).—Magnolia grandiflora, Exmouth variety, would do, but it ought to have a wall of at least 20 feet in height. Escallonia macrantha would suit such a position, and it is fine in foliage, and flowers freely late in the summer.

Names of Plants (*Mrs. L.*).—Lonicera tartarica, Tartarian Upright Honeysuckle. It is one of the hardiest of shrubs; is deserving of a place in every shrubbery, for not only is it highly ornamental, but will grow in any soil or situation. The flowers vary from pink to white. The wood being hard and yellowish-grey is used for making walking sticks and instrument handles. It is a native of eastern Russia. (*T. H.*).—Erysimum cheiranthoides; common name, Treacle Mustard. (*South of Ireland*).—It is so far as we can determine from a spray, Sequoia sempervirens. (*Rev. T. O'Grady*).—Epimedium alpinum, *L.*, var. rubrum, *Hook.* (*Bot Mag.*, t. 5671). (*M. R.*).—3, Alonsoa incisifolia. The Begonia is a florist's variety, which we cannot name. (*Alpha*). —The seeds are apparently those of a Desmodium.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE BLACKTHORN SPRING.

We conclude this must be called a blackthorn spring. We have looked in the country lanes for leaves, and we have seen none. The blackthorn has alone decked the hedges with its flowers, and when this is so southerners know it is to be a bad time for man, and beast, and bird. There is another old-fashioned saying in the south—

> "When the cuckoo comes on the bare bough
> There will be sorrow, and sorrow enou'."

This year the cuckoo came to leafless trees, and the 1875 chicken season has set in very sorrowfully.

Some weeks ago we mentioned the unhappy accounts we had from poultry yards in various parts of England, and we are sorry to hear, in most cases, they have not improved. We ourselves have had many nests of clear eggs, and those from birds which were in the past season marked for their breeding successes. Eggs have not hatched at home, and so it is not to be supposed that they would hatch in nests away from home. Friend after friend we have spoken to on the subject, letter after letter we have received—all have a *rechauffé* of the same grievance. In runs where there were only three or four hens do not seem to be more productive than where the cock had a dozen wives, and we have noticed this as much in Bantams and the smaller breeds as in Cochins or Brahmas; consequently we have heard many complaints this season of quite a new kind. Breeders who last season sold their cockerels and cocks as breeding stock to others are, we hear, frequently receiving letters to say the birds have been useless for breeding, and that the disappointment has been consequently very great, for the best hens had been mated with the new blood, and great things hoped for. Two of our friends have had such letters from purchasers of their stock who, in a burst of indignation, did not hesitate to say that the birds had been tampered with. We can only recommend them to try again.

> "There still is one door open—
> The door of hope, my dear."

And perhaps now, when the suns are really warmer and the whole place brighter, the "tampered with" cockerels may yet be the fathers of exhibition chickens; but it is late—very late. There is hardly time for any spring now, so close are the summer months upon us.

We know of exhibitors of many years' standing—clever men, who go to work quite scientifically—who have this season been quite nonplussed; they could not make out what had come to the birds, or what was wrong with the eggs. Then they compared notes with friends, and found out all were sailing in the same great boat, and that they were no worse off than their neighbours. So they comforted themselves with the reflection that the east winds must have blown from Northumberland to the Straits of Dover, addling the eggs, or incapacitating their producers as it went!

Late chickens are generally a great nuisance; they are in the way of the older birds and give endless trouble; but this year it seems we must either have them or none at all, and hatchings which have generally ended in April must now be carried into June, for surely before then the east winds will have blown themselves out. No one need really be discouraged at their bad luck and give up even yet sitting their hens this season in disgust, as there are so very many companions in adversity, for even in adversity it is pleasant not to suffer alone.

There are some early chickens about; we know of two or three breeders who have done better than commonly, but these were from eggs principally laid in January. The blackthorn had not begun to bud then, for we find that the January eggs hatched very much better than those of February and March; but then, January eggs were "few and far between," and most people do not care for very early chickens, and rest contented till February and March. It is on them that the blackthorn has blossomed so unkindly. Even all the little pet arrangements seem to have failed this year: nests made in warm corners, which have hitherto had such fine broods hatched in them; nests fashioned with warm materials or turf foundations; exact waterings with tepid water; all the wonted careful watchings after hens when off their nests to feed and dust—all these little minutiæ to which in other years we have attributed particular successes, seem to have gone for nothing this season. We can speak from experience—sad experience. We made our nests warm, we watched the sitting hens off and on their nests again, we rained refreshing drops on the eggs, but all to no purpose. Our care was bestowed on "clear" eggs, or eggs whose inmates faintly chipped their shells two or three days after they should have done, and then quietly resigned their baby lives, unable, as Mrs. Dombey before them, "to make the effort."

The few chickens that have been hatched, we hear from many, are mostly feeble and weakly little creatures, and are liable to every kind of ailment—cramp, and cold, and leg-weakness. Truly this blackthorn spring will long be remembered. We look forward to some of the early chicken shows to see what those who generally are to the fore in the early prize lists will do this year. We wonder if they will have managed to procure something early out of the vast poultry resources of Lancashire and Yorkshire, so as still to keep up their ancient prestige, or whether they will send small and juvenile representatives of their breeds, or leave the classes empty and keep their baskets at home. If they think of the latter expedient, surely schedule-framers should look out and take, before it is too late, the advice offered in a friendly contemporary, of specially modifying their schedules to meet this especial emergency.

If this wretched time had been confined to nests of eggs incubated in rooms, and baskets, and cold out-houses, we should have been inclined to think that the dry weather and sharp winds necessitated an extra allowance this year of moisture and heat; but we find ourselves, and hear from many others, that Ducks which made their nests on the ground and had every advantage that Nature can afford, have been equally unsuccessful. So we can only believe that the east winds have been most unusually severe, and that the poultry world has done all it could do, though for the most part in vain.

As regards the results of this blackthorn spring, we are inclined to think they will be one of two. Either we shall have the prices of good cockerels and pullets higher than ever, and have £20 where last season we were content and proud to take £10, or—and we sincerely hope this will not be the case—it will cause a severe check to the fancy, having sickened and wearied some of its best amateur supporters. It will thus have been the first serious stumblingblock in the highway of the poultry world, and those will then begin to laugh who long years ago, in the early days of the fever, prophesied sooner or later some deathblow to what they were pleased to call "an infatuated people." We hope this will not be the case, and though we think the price for birds to be now quite high enough, still we shall gladly hail the first alternative, if it is to be either of the two results.—W.

BROODY HENS.

In the article signed "Hampton-in-Arden," in last week's Journal is the passage, "Out of the large number I keep, I have this spring been able to keep them from becoming broody until quite recently." Now, has any method been pursued to prevent broodiness? If so, would this gentleman tell us what it is?

I keep Brahmas principally, and the fault I find with them is they do not become broody. They have been laying since November almost daily. I feed on hot Indian meal in the morning, sometimes scraps at midday if cold, and a little corn in the evening. They have an excellent grass run and stable-yard. Even now I have only one Brahma pullet broody, the hens laying daily. Two cocks and fifteen hens are my stock.—Sudbury.

ESSEX POULTRY SHOW.

Allow me to inform your readers that a poultry Show was held at Brentwood in the year 1865 in connection with the annual Show of the Essex Agricultural Society, then and there held, and that all the winners of prizes, including Mr. Cresswell himself, were paid their prize-money within a week of the show day, and that all prizes will most certainly be paid in 1875 as

promptly as they were upon the former occasion. I was Hon. Sec. in 1865 as now; and I think, before writing as he has, that it would have been courteous in Mr. Cresswell had he made some inquiry of me as to the probability of his being paid in case he should exhibit and win prizes on this occasion.

It is not for me to vindicate the Essex Agricultural Society from the aspersions cast on it by Mr. Cresswell in ignorance of the facts. I will only say that if he were acquainted with these he would be aware that the Society had nothing to do with the non-payment of the prizes at Stratford in 1874, and that the Show to be held in July next is not "a proposed Essex Agricultural Society's Poultry Show."—R. D. Postans, *Brentwood.*

EPWORTH SHOW OF POULTRY, &c.

The tenth annual Show was held at Epworth on the 7th inst., and was in all respects a great success, the entries being far in advance of those of any former year, and the quality, especially in Pigeons, such as is rarely seen at a spring show.

Game were very many in excess of any previous year, the quality throughout being of the highest character in all the classes. Mr. Matthew's pens were empty, the baskets laying at Crowle station when we left that place after four o'clock in the afternoon. In Black and other Red cocks Mr. Martin won with a grand bird, a Brown Red, in which it would not be possible to find many faults; second being a handsome bird of the same colour and locally bred. The Black Reds were not so well up in quality as the Brown Reds, the same remarks applying to the hen class as well, the winners Brown Reds, the first very good, and second losing only from being a little broody, while by far the best pen in the class was left out on account of the face being unnaturally black. Cocks, Any other colour, were first and cup for Game and Yellow-legged Pile, very hard and close-feathered, and second a smart nice-coloured Duckwing. Pen 108 was also a good one of that variety. In hens was as good a Duckwing as has been seen of late, and a Pile second. *Dorkings* good but few in number, as also the *Spanish*, the cup for the next section going to this class. In Mrs. Altsep's pen the hen was dying when the awards were made. In *Brahmas* the winners were very good, but the first-prize hen had a large tumo[illegible]r on her breast, and it is a question if this should have been passed over, though we observed her in the same position at the Wharfedale Show on the following day. *Cochins* were a fair lot, Buffs winning. *Hamburghs* and *Polands* were not large entries, but there were some capital pens in all classes, Silver and Gold winning respectively in Polish. La Flèche and Black Hamburghs won in the Variety class, Sultans being also noticed. There were classes for single cocks and single hens except Game, in which Spanish were placed first, the hen referred to being especially fine. *Bantams* were shown singly, and were good classes. In Red *Game Bantam* cocks the first was by far the best Brown Red we have ever seen, and this bird won the cup easily; the second a Black Red was a grand bird, but minus one sickle. In hens of that colour both winners were Black Reds, both of which were good in all points, although the latter was somewhat larger than is desirable. Cocks, Game, any other colour were first a real good Duckwing, and second a Pile; and in hens the first was an exceedingly neat Pile, and second Duckwing. In Bantam cocks, any other variety, the winners were Blacks, the first in fine bloom, and second good but short of one sickle feather; and in the hens the first was Black and second Silver Sebright. The Selling class was bad except the first-prize Spanish. *Ducks* seemed to be quite a failure. Some pens were empty, many arriving late.

Pigeons, as before hinted, were the best section, every class being well filled, but on account of the unexpected influx of entries the pens had to be placed so high as to prove most inconvenient for the Pouters, which should in all cases be placed under the eye, as is often proved by the reversal of awards in the different positions. Carriers were a good class, but some of the pens were a little too dark for easy inspection, while all the rest were in much better positions. A Dun cock was placed first, this bird being the cup-winner on the following day; second a Dun hen, and third a Black cock (Baker). The eye of this bird having been slightly injured, prevented his taking a high position. Pouters a grand display of twenty-one entries, and not one really bad bird. The first a Blue cock of grand proportions; second a Black, almost equally good; and third a Blue, very fine in all respects. Mr. Nottage's pens were empty. Fifteen birds received notices. Tumblers, any colour, were all Short-faces; the first and cup for best pen in the Show, an exquisite Almond in every respect; second a Kite which we believe is unequalled, and third an Agate. Some other good Almonds were shown, but many were too dark and muddy in feather. Jacobins were a large but not a good class; first was a capital Red, second a Yellow, and third White, both very good. In Fantails were some grand birds. First a very small White of high carriage and grand motion; second a larger bird but yet very good; third a Blue, small and good in all respects. Turbits were almost a puzzle, so close was the competition. First a Silver, second a Red, and third a Shell-crowned Black, all perfectly clean-thighed, with good hog manes, gullet, and curl, although some were not so short and stiff as to please those who go in for head properties alone, and which we look upon as a great mistake. Magpies a good class, Yellow, Red, and Black coming to the front. In Barbs the first was Yellow, capital in skull, and second and third Blacks, the latter a little spouty. In Antwerps the first was a very good Silver Dun Short-face; second a Red Chequer, very good in head; and third a Silver Dun, not in the best condition. Dragoons were about one of the best classes in the Show. A Red of splendid colour and almost perfect head was first; second a Blue, fine in all respects, and third a strong Grizzle, all cocks, though there were some fair good hens, pen 434 especially a perfect bird. In the Variety class the prizes were awarded in duplicate, this being such a class as is rarely seen. The first a Blue Owl (Foreign), the smallest and most perfect in all respects but eye, which was a little yellow, the bird being very young; extra first a Black Mottled Trumpeter, evidently a cross from the English, and imported, good in all properties and splendid in foot-feathering; second and extra second, Spangled Ice and Pigmy Pouter; third a Blondinette, and extra third a Black Capucian. In the Selling class the first was a Red Jacobin; second a Red Barb, and third a Magpie. Mr. Baker won the cup for points in Pigeons.

Cage Birds were about as numerous but not as good a section as that of last year, though winners, as a rule, were quite up to the mark. In Yellow Canaries first was a Norwich, and second a Manchester Coppy. Buffs containing a grand highly fed Norwich. A specially good Green won in the next class; the second being a Variegated. Neither Goldfinches nor Linnets were as good as in previous years, but it would be quite difficult to meet with more perfect birds than the winners. In the Variety class the first was a Dun Norwich, second a Bullfinch, and third a Dun.

Rabbits had two classes, the Lops proving a good lot. First was a yellow-and-white doe, said to be 24 inches in ear, but with our known easy measurement quite 23 by 4¾ inches, and yet these were not the best properties of this Rabbit, the style, aleekness, and carriage being such as must be seen to be understood. Second a tortoiseshell doe, 21 by 4½ inches in fine order. Highly commended fawn-and-white, 21 by 4¾ inches; fawn doe 21 by 4¾ inches; grey-and-white 21¼ by 4½ inches; fawn buck 21¾ by 4¾, and a tortoiseshell doe 21¼ by 4¾ inches. In the Variety class first was a grand Silver-Grey buck; second a very good Himalayan, and third Belgian Hare. Very highly commended Mr. Swetman's Angora doe, which, however, needs grooming, her hinder quarter carrying as much matted wool as would make a small bolster.

Of *Cats* there were but three, any of which was well fit for the show pen. First a good Persian rather dirty; second a Black, and third a Red Tabby. The whole Show was judged by Mr. Hutton.

Game.—*Black-breasted and other Reds*—*Cock.*—1 and *hc*, J. Cock, Worcester. 2, Miss F. Rimington, Epworth. *vhc*, Salea & Bentley, Crowle; Spence and Cavill, Sheffield; J. F. Walton, Rawtenstall. *Hen.*—1, W. G. Waters, Elsham. 2, H. E. Martin, Sculthorpe. *vhc*, Dr. A. Cameron, Epworth. *hc*, Dr. A. Cameron; G. Oultram, Belton. *c*, G. H. Fitzherbert, Sevenoaks.

Game.—*Any other colour.*—*Cock.*—Cup and 1, J. F. Walton. 2, J. A. & H. H. Staveley, Driffield. *vhc*, H. Butler, Hennor. *hc*, G. H. Fitzherbert; W. G. Waters. *c*, S. Matthew, Stowmarket. *Hen.*—1, Salea & Bentley. 2, J. F. Walton. *hc*, E. Winwood, Worcester; G. Yates, Thorne; J. Wright; J. N. Jackson, Newark.

Dorkings.—1, W. Harvey, Sheffield. 2, J. Chester, Thorne. *hc*, J. H. Heather, Retford (2); Mrs. E. Allsopp, Worcester.

Spanish.—1, H. Beldon, Bingley. 2, J. Powell, Bradford. *hc*, E. Brown, Sheffield. *c*, J. Parker.

Brahmas.—1, W. Whiteley, Sheffield. 2, J. F. Smith, Sheffield. *hc*, W. G. Waters; W. Harvey; J. F. Smith. *c*, Dr. J. Holmes, Chesterfield.

Cochins.—1, Mrs. E. Allsopp. 2, S. R. Harris, Cusgarne. *c*, C. Wilson, Eton; Lowley & England, York; T. Pierson, Pickering.

Hamburghs.—*Golden-spangled.*—1, H. Beldon. 2, G. Holmes. *Silver-spangled*—1, H. Beldon. 2, G. Holmes.

Hamburghs.—*Golden pencilled.*—1, H. Beldon. 2, C. Judson, Peckham. *hc*, J. Smith, Lincoln. *Silver-pencilled.*—1, H. Beldon. 2, R. W. Bracewell, Earby, Leeds.

Polish.—1, H. Beldon. 2, A. & W. H. Silvester, Market Hall, Birmingham.

Any other Variety.—1, E. Walton, Horncliffe, Rawtenstall. 2, H. Beldon. *hc*, A. & W. H. Silvaster.

Any Variety Except Game.—*Cock.*—1, J. Powell. 2, Wells & Ayre. *hc*, E. Winwood. *Hen*—1, J. Powell. 2, E. Winwood. *hc*, J. F. Walton; J. Earnshaw, Rotherham; Wells & Ayre. *c*, A. Spencer, Driffield.

Game Bantams—*Black-breasted and other Reds.*—*Cock.*—Cup and 1, W. F. Entwisle, Bradford. 2, E. Walton. *vhc*, T. S. Stephenson, Newbegin, Beverley. *hc*, W. D. Little, Blackheath; C. E. Wallace, Wavertree; G. Holmes. *c*, W. Taylor, Sculthorpe; Dr. A. Cameron. *Hen.*—1, W. F. Entwisle. 2, E. Walton. *hc*, W. Taylor; J. Clifton, Hatfield; G. Lewis.

Game Bantam.—*Any other colour.*—*Cock.*—1, E. Dawson, Epworth. 2, A. Smith, Halifax. *vhc*, R. J. Hartley, Altrincham. *hc*, Salea & Bentley, Crowle. *c*, W. F. Entwisle. *Hen.*—1 and *vhc*, E. Dawson. 2, W. F. Entwisle. *hc*, W. G. Galloway, Bowden; A. Smith.

Bantams.—*Any variety except Game.*—*Cock.*—1, R. H. Ashton, Mottram, Manchester. 2, Miller & Beanland, Keighley. *vhc*, A. & W. H. Silvester. *hc*, W. H. Young, Driffield. *Hen*—1, A. Smith. 2, A. & W. H. Silvester. *hc*, W. G. Water; R. H. Ashton; Milner & Beanland.

Selling Class.—1, J. Powell. 2, J. Smith.

Ducks.—*Aylesbury or Rouen.*—1, C. Young, Driffield. 2, Z. G. Maw, Newland. *Any other variety*—1, A. C. Bradbury, Nuthall, Nottingham (East Indian).

PIGEONS.

Carriers.—1, E. Horner, Harewood, Leeds. 2, H. Yardley, Market Hall, Birmingham. 3, J. Baker, Kew Bridge, London. *vhc*, H. Yardley; E. Horner, Harewood, Leeds. *hc*, J. E. Crofts, Worksop; E. Heath. *c*, A. H. Clark, Old Swinton.

Pouters.—1, J. E. Crofts. 2 and *vhc*, J. Hairsine, Hull. 3, W. Harvey. *hc*,

H. Yardley; J. E. Crofts; Mrs. Ladd, Calne (2); A. Preston, Spalding; E Horner; J. Baker (3).

TUMBLERS.—1, Cup, and 3, H. Yardley. 2, J. Baker. *vhc*, H. Yardley; J. Baker (2). *hc*, A. & W. H Silvester (3); W. Allen, jun., Mexborough; E. Horner. *c*, J Gardner, Preston.

JACOBINS —1, T. Holt, Bradford. 2, E. Horner. 3 and *vhc*, J. Baker. *hc*, J. E. Crofts; W. Barvey; T. Holt, Bradford.

FANTAILS.—1 and 2, J. Baker. 3, S Lawson, Preston. *hc*, J. F. Loversidge, Newark; H. Yardley; T. Pierson; J. Walker, Newark; T. S. Stephenson; A. Smith; W. J. Warhurst.

TURBITS.—1 and 3, J. Baker. 2, T. S. Stephenson. *vhc*, H Yardley; Miss F. Seanor, Leeds. *hc*, A. & W. Silvester; J. Baker. *c*, Pickering & Duggleby, Driffield; Wells & Ayre; E. Horner.

MAGPIES.—1, Miss F. Seanor. 2, J. E. Crofts. 3, M. Ord, Sedgefield, Durham. *vhc*, E. Horner. *hc*, H. Yardley; J. E. Crofts; E. Horner.

BARBS —1 and *vhc*, J. Baker. 2 and 3, E. Horner. *hc*, H. Yardley (2); C. Wroot, Hull. *c*, J. E. Crufts.

ANTWERPS.—1, J. Gardner. 2 and *vhc*, W. F. Entwisle. 3, H. Yardley. *hc*, J. Hairsine. *c*, H. Gough, Wolverhampton.

DRAGOONS.—1 and *vhc*, E. Heath, Blackburn. 2, R. Woods, Mansfield. 3, W. G. Watera *hc*, H. Yardley; R. Woods; Miss F. Seanor; J. Baker (2). *c*, H. Yardley; E Horner.

ANY OTHER VARIETY.—1, J. Baker (2). 2, A. & W. H. Silvester (2). 3, H. Yardley; E. Heath. *hc*, H. Yardley; A. & W. H. Silvester; M. Ord; W. Harvey (2); J. Baker (2). *c*, Miss F. Seanor; B. Hudson, Driffield; E. Horner.

SELLING CLASS.—*Single Bird.*—1, R. G. Sanders, Beverley. 2, C. Wroot. 3, E. Horner. *hc*, J. Baker; R. G. Sanders. 3, H. Yardley; A. Smith.

CAGE BIRDS.

CANARY.—*Yellow.*—1, H. N. Fosbrooke, Leeds. 2, B. Hanson, Thorne. *hc*, T. Green, Gainsborough. *Buff.*—1, W. G. Waters. 2, T. Green. *Green or Variegated.*—1, T. Green. 2, H. N. Fosbrooke. *hc*, H. N. Fosbrooke; T. Green. *c*, W. Gravill, Thorne; R. Pearson, Whitby.

GOLDFINCH.—1 and 2, C. Marshall, West Stockwith. *vhc*, J. Boyes, Epworth. *hc*, W. Gravil; G. Yates (2); T. Green; S. Whitehead, Haxey.

LINNET.—1, R. Pearson. 2, J. J. Temperton, Butterwick. *hc*, T. Green; Master W. B. Hudson, Epworth; J. Boyes.

ANY OTHER VARIETY.—1 and 2, R. Pearson (Bullfinch) 3, T. Green. *hc*, R. Pearson (Goldfinch Mule); F. Bramhill (Blackbird); Master F. Allen, Epworth (Parakeet); J. Coker, Hull (African Love Bird, Love Bird, and Cut Throat).

RABBITS.

LOP-EARED.—*Buck or Doe.*—1, W. Allison. 2, H. Pickworth, Spalding. *hc*, H. Pickworth, Spalding; F. and E. J. Fell, Blackburn; A. Hudson, Hull (2); W. H. Ottley, Worksop; J. Mann, Burton-on-Trent. *c*, F. and E. J. Fell; T. Green, Crowle Wharf.

ANY OTHER BREED.—1, A. Hudson (Silver-Grey). 2, G. Kirkby, Sheffield (Himalayan). *vhc*, H. Swetman, Fulford (Angora) *hc*, G. C. Livett, Soham (Belgian Hare); E. Stubbs, Spalding; F. Sabbage, Northampton (2); A. Canty, Barton-on-Humber. *c*, R. H. Glew; H. Pickworth (Dutch); W. G. Watera (Himalayan).

CATS.—1, T. Steel, Epworth (Angora). 2, Miss Skelton, Burnham. *hc*, J. R. Haraley, Althorpe.

CRESTED NORWICH CANARIES.

(Continued.)

FIRST-CLASS Crested Norwich birds are few and far between, and are somewhat difficult to obtain even when bred from the best of stock. From strains which have made some marks at exhibitions it is more likely that promising specimens may be bred. It is not an everyday occurrence that crested birds possess the essential qualifications—namely, high condition, quality, and closeness of feather, and having a full-flowing perfectly formed dark crest.

Much to my gratification whilst at the last famous Darlington Bird Show, I was pleased to find so exquisite a specimen (as is represented in our engraving) upon the show stage. The class in which it was exhibited contained twenty-nine birds, many of which were of high merit, and for one in particular to head the lot is conclusive evidence that it was justly entitled to the beautiful silver medal it gained on that occasion—the gift of the Judge who had the honour of awarding the prizes. Excepting in one instance (that of Belfast Show, where the famous bird was defeated by a Manchester Coppy bird) the bird has defeated all comers in various parts of England, and as the owners of it have remarked, "rarely failed to bring home just honours."

In my remarks upon Crested Norwich Canaries, page 360, I briefly described the characteristics of them in the respective classes in which they were exhibited. Next to the even-marked crested are classed those with dark, grizzled, or clear crests, and it is to the foremost of these varieties we now refer. The specimen shown by Messrs. G. & J. Mackley, Norwich, in class 13 (No. 437) at the last Crystal Palace Show, stood at the head of forty-eight others—a glorious triumphal finish to the past season. The bird has a fine dark crest, every feather of which is as it should be. Altogether the bird is most attractive in appearance. It has been put up for breeding purposes, with a tolerably good prospect that some of its offspring may follow the parental example.

It may be interesting to state some of the shows at which Messrs. Mackley's bird played a prominent part:—Norwich, Darlington, Lowestoft, Fakenham, Yarmouth, Belfast, Baildon, Reading, Crystal Palace, &c.

Mem., dated May 3rd.—"We are glad to say he is up breeding, and looks like a 'star.' His hen has five good eggs, and expect her to hatch this week."—GEO. J. BARNESBY.

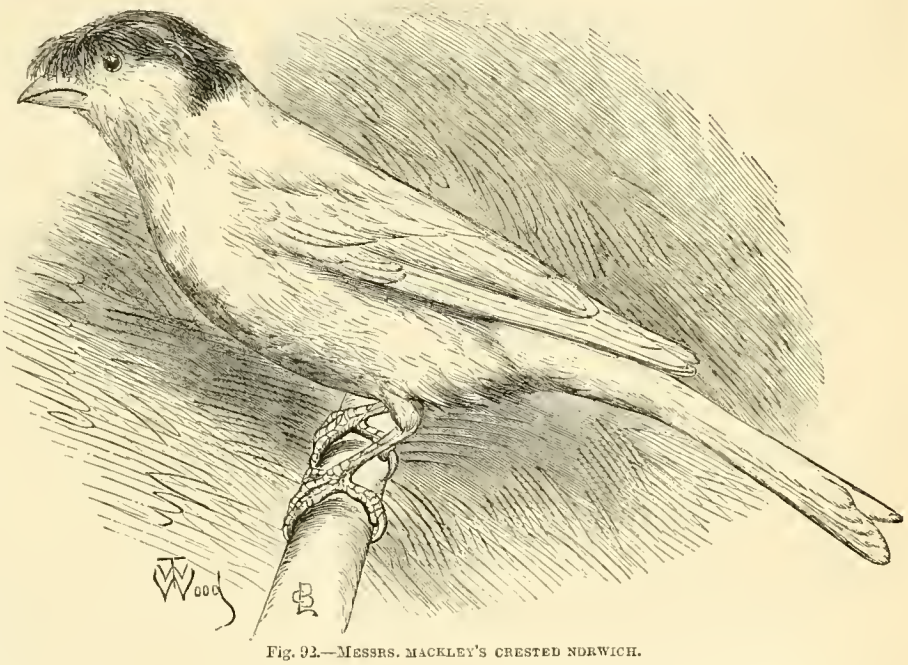

Fig. 92.—MESSRS. MACKLEY'S CRESTED NORWICH.

STACKSTEADS POULTRY SHOW.

THE Show of Poultry, Pigeons, and Rabbits in connection with that of agriculture generally was held on Thursday last, a small paddock being devoted to the purpose of poultry, &c. Turner's pens were used and fixed on three sides of the field, the entries of poultry being very small, while those of Pigeons and Rabbits were large.

In *Game* the cup was won by Mr. Brierley with Brown Reds; Messrs. Walton's Piles running close for that honour. *Dorkings* were only poor, and the *Spanish*, of which there were but two pens, do not call for special notice, while *Cochins* were pretty good in both classes. In *Brahmas* the awards might with advantage have been reversed, the second being by far the best. Messrs. Duckworth, Fielding, and Robinson divided the prizes in *Hamburghs*, these only being birds of any note. In Game *Bantams* Black Reds of good quality won the cup, but we did not agree with the awards in the next class, for though the Piles in the first-prize pen were good, yet the second-prize pen had not pretensions in common with the Brown Reds in pen 235, which were commended. A class was provided for White Bantams, the first being a nice pen, but the rest only poor. In the next class Blacks were the winners, and these were very good. In the Selling class the first and second were Dark Brahmas, and very good for the price.

In *Ducks*, *Geese*, and *Turkeys* Mr. Walker's well-known stud was well to the front, these classes being about as good as any in the Show. There were several classes for local exhibitors, and some of the birds were quite equal to those in the ordinary classes.

In *Rabbits* the Angoras were first on the list, but these were badly placed, the second-prize Rabbit being by far the best, and in Himalayans the first was poor in all respects; the second ought to have occupied that position, and the second prize should have gone to pen 326, Hey of Rochdale. Lops were a good entry, Mr. Irvine winning both prizes; first with a Tortoiseshell doe, and second with a Black-and-white, both good Rabbits, but second by far the best, and we believe this was a reversal of all preceding decisions.

In *Pigeons* Carriers were first, and, as in all classes, were shown in pairs. The winners were Blacks but not in high

condition. In Tumblers Kites were first, but we preferred the second-prize Blue Balds to them. Barbs were well placed, the Red cock in the first-prize pen was a gem; equal second being awarded to Yellows and Blacks. In Owls the awards were made to Foreign birds, the first to White and second to Blues. Mr. Richmond's pair of Blue English should by all means have been noticed. In Pouters the first were White, and second Red, the class only poor. Fantails were good and well placed. Turbits being first Yellow, and second White. In Dragoons we would have placed Mr. Wood's bird in a higher position, the winners were Blue. Trumpeters were good, but only one prize was awarded. Red Chequers were first in Antwerps, two seconds being awarded to Silver Duns. In the Variety class the first were Black Fairies, second Black Magpies, and equal second plain-backed Ice Pigeons.

GAME.—*Black or Brown Reds.*—Cup, 1, and *vhc*, C. W. Brierley, Middleton. 2, R. Payne, Brierfield. *hc*, J. Fletcher, Stoneclough. *Any other variety.*—1, J. F. Walton, Rawtenstall. 2, J. Fletcher.

DOBBINGS.—1, J. Walker. 2, W. H. King, Sandfield, Rochdale. *hc*, J. Stott, Healey, Rochdale; W. H. King; J. H. Ashworth, Broadley, Rochdale.

SPANISH.—*Black.*—1, H. Wilkinson, Earby. 2, J. Thirsk, Bradford.

COCHIN-CHINAS.—*Cinnomon and Buff.*—1, J. Walker. 2, J. Royle, Manchester. *Any other variety.*—1, J. Walker. 2, T. & F. Aspden, Church, Accrington. *hc*, A. Bamford, Middleton.

BRAHMA POOTRAS.—*Light or Dark.*—1 and 2, T. F. Ansdell, Cowley Mount, St. Helen's.

HAMBURGHS.—*Golden-pencilled.*—1 and 2, G. & J. Duckworth, Church. *Silver-pencilled*—1 and *hc*, J. Robinson, Garstang. 2, J. Patrick, Stacksteads. *Golden-spangled*—1 and 2, G. & J. Duckworth. *Silver-spangled.*—1 and 2, J. Fielding, Newchurch. *Black.*—1, J. Robinson. 2, W. Bentley, Holmfirth. *hc*, J. H. Hoyle, Newchurch; E. Walton.

GAME BANTAMS.—*Black or Brown Red*—Cup, W. F. Addie, Preston. 2, E. Walton. *hc*, W. F. Entwisle, Westfield, Bradford (2); W. F. Addie. *Any other variety.*—1, Bellingham & Gill, Burnley. 2, J. Riley, Accrington. *hc*, J. R. Fletcher. *c*, W. F. Entwisle.

BANTAMS.—*White, Clean-legged*—Cup, T. Green, Crawshawbooth. 2, T. Cropper, Bacup. *Any other variety.*—1, J. A. Dakin, Roe Cross, Mottram. 2, T. Cropper. *c*, H. B. Smith, Broughton, Preston; North & Wood, Fartown, Huddersfield.

FRENCH.—1, E. Walton. 2, R. A. Boissier, Penshurst.

ANY OTHER VARIETY.—1, T. Cropper. 2, A. A. Vander Meersch.

SELLING CLASS.—1 and 3, A. Bamford. 2, K. Dawson, Shaw, Oldham. *hc*, A. & J. Trickett, Waterfoot.

DUCKS.—*Aylesbury.*—1 and 2, J. Walker. *Rouen.*—1, J. Walker. 2, A. West, Worsthorne, Burnley. *hc*, E. Snell, Harrowden, Stamford. *Any other variety.*—1, J. Walker. 2, H. B. Smith, Preston. *vhc*, J. Walker; H. B. Smith; A. & J. Trickett.

GEESE.—1 and 2, J. Walker.

TURKEYS.—1, J. Walker. 2, J. Shorrocks, Bacup.

DISTRICT CLASSES.

GAME.—1, J. Patrick, Stacksteads. 2, E. Brown, Rawtenstall.

DORKINGS, SPANISH, COCHINS, OR BRAHMAS.—1 and 2, W. Hargreaves, Bacup.

HAMBURGHS.—1, J. Fielding. 2, L. Dearden, Stacksteads.

BANTAMS.—1, F. E. Furness, Rawtenstall. 2, E. Furness. *hc*, T. Cropper; J. Hoyle, jun.

FOWLS OR DUCKS.—1, Furness & Sudall, Rawtenstall. 2, A. & J. Trickett. *hc*, E. Lord, Bacup; A. Taylor.

PIGEONS.

CARRIERS.—1 and 2, J. Stanley, Blackburn. *hc*, H. Yardley, Birmingham.

TUMBLERS.—1, W. J. Warhurst, Staleybridge. 2, H. Yardley. *hc*, R. White, Manchester.

BARBS.—1, R. White. 2, J. C. Boothley, Stockport. *vhc*, J. Stanley. *hc*, H. Yardley; A. A. Vander Meersch.

OWLS.—1 and 2, T. Kirby, Rochdale. *hc*, J. C. Boothley; A. Warburton, Haslingden.

POUTERS OR CROPPERS.—1 and 2, W. J. Warhurst.

FANTAILS.—1 and *hc*, W. J. Warhurst. 2, J. Chadwick.

TURBITS.—1, E. Heath, Blackburn. 2, F. S. Barnard, Tottenham. *hc*, T. Cropper.

DRAGOONS.—1, W. J. Warhurst. 2, J. Stanley. *hc*, R. Woods, Mansfield (2); J. Stuttard, Colne; W. J. Warhurst; C. A. Pearson, Walton-on-the-Hill.

TRUMPETERS.—1, A. A. Vander Meersch.

JACOBINS.—1, A. A. Vander Meersch. 2, J. Richmond, Oswaldtwistle.

ANTWERPS.—1, J. Stanley. 2, W. Harrison, Burnley; B. Robinson, Burnley. *hc*, J. S. Collier, Wellfield, Rochdale; R. White. *c*, J. A. Wilkinson, Rochdale; G. Thickett, Rochdale.

ANY OTHER VARIETY.—1, J. Richmond. 2, W. J. Warhurst; R. White. *hc*, E. Heath.

RABBITS.

ANGORAS.—1, S. Buckley, Healey, Rochdale. 2, J. Hallas, Huddersfield. *hc*, R. A. Boissier. *c*, J. W. Harling, Burnley.

HIMALAYANS.—1, J. Booth, Coupe, Manchester. 2, R. Hopkinson, Fishpool, Bury. *hc*, R. Hopkinson; W. Hey, Rochdale; J. Hallas.

ANY OTHER VARIETY.—1 and 2, J. Irving, Blackburn. *hc*, R. Hopkinson. *c*, A. Chew, Bacup.

JUDGES.—*Poultry:* Mr. Simon Fielding, Trentham, Stoke-on-Trent; Mr. James Dixon, North Park, Clayton, Bradford. *Pigeons and Rabbits:* Mr. Thomas Ridpeth, Park View, Withington, Manchester.

WHARFEDALE POULTRY SHOW.

THE seventy-seventh annual Show was held at Otley on Saturday last, and substantial prizes being offered the entries were considerably in excess of those of any previous year, this being the case more especially in the Pigeons, where several classes had been added for that popular Yorkshire peculiarity the Antwerps, a cup also being given. The pens were rather of the old-fashioned kind, and these being nearly worn out we would advise a change for more modern ones.

There were eight classes for *Game*, and the quality of birds was good, though the cup being awarded to Black Reds, Messrs. Mason's Piles standing well for that position. *Spanish* was a good class; first a good pair, second a splendid hen and fair cock, third a grand cock but moderate hen. In *Cochins* first and third were Buffs and second White, all good pens. The class was good. Dark *Brahmas* good, but Light very poor. The *Dorkings* also being unusually good. In *Polands* the cup was awarded to Golden, the second and third going to Silvers. *Hamburghs* were good throughout, and the winners well placed, the cup going to Gold-spangles. The *French* classes were only moderate. *Bantams*, Black Red, were first a grand cock but poor hen with white ears; second a good pen, and third moderate. Pen 168 contained the best hen in the Show. In Brown Reds the first was an error, the second being at least equal in the hen, was much better in head, eye, breast, and colour of the cock; third also being a smart pen. In Any other colour Duckwings were first, these being little gems; second Piles, the cock good but hen poor; the third were Duckwings. In Single cocks, first was a Black Red good in all points but tail, which is far too heavy, the cup was awarded here; the second and third Piles, good in style, but a little short of colour on the wing ends. Black Bantams were a good class, the winners small and neat. In the next class Silver Sebrights were first, White second, and Silvers third. A pen of handsome Sultans were placed first in the Variety class, Silkies being second and third.

In *Ducks*, Rouens were good and well placed, Aylesburys being good but not numerous. In the Variety class Mr. Walker's Chilian Teal were a grand pair, in fact the class was good; the second being Mandarins, and third Whistlers.

Pigeons were a heavy entry, many new classes having been offered, a cup for the best pen in the Show being awarded to Mr. Horner's Dun Carrier cock, the cup for Antwerps being won by Mr. Entwisle with a well-shown Short-faced Silver Dun, while a cup for the most successful winner of money prizes, given by Mr. Horner, was won by that gentleman himself. Pouters were first on the list, all the winners being Blues, good in all points, and placed in a good position they showed to great advantage. Carriers were—first and third Duns, and second Black. In Barbs the first was a Dun hen not in the best order, second a Red, and third Black. Jacobins were won by the same exhibitors with good Reds. In Dragoons the first was a Silver a little too spindly, second a better Red, and third a good Blue hen. Pen 335, a grand hen, might have been placed with justice. In Short-faced Tumblers the winners were all Almonds, Mr. Yardley's bird being first; second a fair bird, but too dark in tail; and third a rich bird, but muddy and indistinct in spangling. Long-faced Tumblers were a small class, but the Baldpates were good, though the awards in two cases were made to Mottles. Fantails did not strike us as anything extra as a class, but the Turbits were very good; first a Silver, second Red, and third Yellow. Trumpeters were all of the foreign kind, immense in rose and shell, but poor in foot-feather. English Owls were a large class, but not so good as we expected to see, though the winners were good; the first and third Silvers, and second Blue. In Foreign Owls the winners were White, good and well placed. In Magpies, first Red, second Yellow, and third Black; a very good class. In six classes of Antwerps were eighty-one entries—a show in itself in fact, and the quality almost a puzzle for any judge, the classes being divided into cocks and hens of the three varieties—viz., Short-faced, Medium, and Long. In Short-faced cocks the winners were Dun, the first in fine bloom; several other birds also good, but the hens of that variety were poor as compared with the cocks. Long-faced cocks were a grand class, the winners Red Chequers, and all from one exhibitor. Medium-faced cocks were also good, but some birds shown were really Long-faces, but the first was well placed on a Silver Dun of great beauty and quite young, the second and third being Red Chequers. In Long-faced hens again the winners were Red Chequers and very good, though the first was a little short of colour. In Medium-faced hens first and third were Red Chequers, and second Dun; all very good. Swallows were a good class. The first, a Red, was well placed, being a perfect bird; the second a Yellow, and third also a Red. In Archangels Mr. Vander Meersch won with ease, yet the class was good. One of the finest Runts we have seen for some time was placed first in the Variety class, the second going to a nice Pigmy Pouter, and third to a good Nun. The Selling class was poor in all respects.

Rabbits were not a large entry, although there were four classes. In Lops the first went to a Grey-and-white doe of nice style, 22 by 4¾; second to a Fawn doe, 21½ by 4¾, in nice order; and third to 21½ by 4¾. Pen 575, a Tortoiseshell buck, was about the best styled Rabbit shown, good in colour and fine in condition. Angoras were good and well placed, as also the Himalayans, the winners being very good in points. In the Variety class the first was a Silver-Grey, which is so well known as to need no comment; the second, a Silver-Grey, was a little dark on the head; the third being a Tortoiseshell Dutch, large, but well marked.

GAME.—*Black Red.*—1 and Cup, E. Aykroyd, Eccleshill. 2, R. Hemmingway, Shelf. 3, W. Spencer, Haworth. *Brown Red.*—1, E. Aykroyd. 2, W. Ormerod, Walsden, Todmorden. 3, J. Cock, Worcester. *Duckwing Game.*—1, E. Aykroyd. 2, E. Winwood, Worcester. 3, W. Spencer. *Any other colour.*—1 and 2, H. C. and W. J. Mason, Birstal. 3, R. Walker, Gomersal.

GAME.—*Red.—Cock.*—1, E. Aykroyd. 2, H. E. Martin, Sculthorpe, Fakenham. 3, A. Clayton, Allerton, Bradford. *Hen.*—1 and 2, E. Aykroyd. 3, W. Ormerod. *hc*, H. E. Martin.

GAME.—*Any other variety.—Cock.*—1, H. C. & W. J. Mason. 2, E. Aykroyd 3, J. A. & H. H. Staveley, Tibthorpe. *Hen.*—1, E. K. Fox, Clayton Heights. 2, E. Aykroyd. 3, E. Winwood,

SPANISH.—1, H. Beldon, Goitstock. 2, R. Newbitt, Epworth. 3, T. Holt, Bradford. *hc*, H. Beldon (2); J. Holt, Bradford.

COCHINS.—1, J. Walker, Spring Mount, Rochdale. 2, H. Beldon. 3, Mrs. Allsopp, Worcester. *hc*, E. Winwood; T. H. Readman, Whitby. *c*, R. H. Feltoe, York.

BRAHMA POOTRAS.—*Dark.*—2, C. Holt, Rochdale. 3, J. F. Smith, Sheffield. *hc*, J. Walker, Rochdale. *c*, E. Williams, Sharrow, Ripon. *Light.*—1, R. E. Horsfall, Liverpool. 2, S. Lucas, Hitchin. 3, H. Beldon.

DOSKINGS.—1, J. Walker, Rochdale. 2, J. Newton, Silsden. 3, W. H. King, Sandfield, Rochdale. *hc*, J. Newall; W. Harvey Sheffield.

POLANDS.—Cup, 1, 2, and 3, H. Beldon. *hc*, T. Dean, Keighley.

HAMBURGHS.—*Golden-spangled.*—1, Cup, and *hc*, J. Rollinson, Lindley. 2, T. Dean. 3, H. Beldon. *Silver-spangled.*—1, 2, and 3, H. Beldon.

HAMBURGHS.—*Golden pencilled.*—1, 2, and 3, H. Beldon. *hc*, C. Judson, Peckham. *Silver-pencilled.*—1, 2, and *hc*, H. Beldon. 3, T. Hanson, Keighley.

HAMBURGHS.—*Black*—1, 2, and 3, H. Beldon. *hc*, C. Taylor, Gilstead. *c*, T. W. Holmes, Baildon (2).

HOUDANS.—1 and 3, H. Grant, Bradford. 2, R. A. Boissier.

FRENCH.—*Any other variety.*—1, B. Grant. 2, Mrs. J. Wicks, Appleby, Brigg. 3, C. M. Sannders.

GAME BANTAMS.—*Black Reds.*—1, A. Sogden, Cleckheaton. 2, F. Steel, Hipperholme. 3, J. Rushworth, Keighley. *hc*, W. F. Entwisle, Westfield, Bradford; E. Jennings, Stanningley; W. Adams, St. Clements, Ipswich; J. Rollinson; R. Frew, Kirkcaldy. *Brown Red.*—1, F. Steel. 2, W. F. Entwisle. 3, E. Jennings. *hc*, F. Steel; W. F. Entwisle. *c*, R. Frew; F. Steel.

BANTAMS.—*Any other colour.*—1, R. Newbitt, Epworth. 2 and 3, F. Steel. *hc*, J. Wright, Wibsey.

GAME BANTAMS.—*Cock.*—1 and Cup, J. Blamires, Great Horton. 2 and 3, F. Steel. *hc*, E. Jennings. *c*, Wells & Sherwin, Ripon.

BANTAMS.—*Black*—1 and 2, H. Beldon. 3, Milner & Beanland, Keighley. *hc*, J. H. Cartwright, Willington; A. G. Mitchell, Bishop Auckland. *c*, W. H. Young, Driffield; R. Frew. *Any other variety.*—1, A. Silvester. 2, H. Beldon. 3, R. Frew. *hc*, R. A. Boissier; R. Frew; T. Crepper, Bacnp.

ANY OTHER VARIETY.—1, B. Beldon. 2, S. P. Ashley, Otley.

DUCKS.—*Rouen.*—1, J. Walker, Rochdale. 2, J. Newton. 3, F. Snell, Barrowden. *hc*, W. H. Rawson, jun.; F. G. S. Rawson, Thorpe, Halifax. *Aylesbury.*—1, E. Snell. 2, C. Holt. 3, J. Walker. *Any other variety.*—1 and 3, J. Walker. 2, A. Silvester. *hc*, H. B. Smith (2).

SELLING CLASS.—1, T. Holt, Bradford. 2, W. Lawson, Beamsley. 3, H. Grant, Bradford. *hc*, A. W. Dear; F. G. S. Rawson (2); S. Ackroyd, Undercliffe; R. Newbitt, Epworth; T. Calvert; C. Carr, Wilsden, Bingley; J. Naylor, Goodley, Keighley; H. Beldon. *c*, P. C. Bedlington, Whitby; H. Pawson, Burley-in-Wharfedale.

GEESE.—1, J. Walker. 2, F. G. S. Rawson. 3, E. Snell.

PIGEONS.

POUTERS.—1, W. Harvey, Sheffield. 2 and 3, W. Nottage, Northampton. *hc*, H. Yardley, Birmingham; F. Seanor, Leeds; E. Horner, Harewood.

CARRIERS.—Cup, 1, 2 and *hc*, E. Horner. 3, H. Yardley. *c*, J. Holden, Wibsey Slack.

BARBS.—1 and 2, W. Harvey. 3, H. Yardley. *hc*, J. Thresh, Bradford; E. Horner (2). *c*, H. Yardley.

JUDGES.—*Poultry:* Mr. James Dixon, Clayton, Bradford; Mr. John Martin, Baschurch, Salop. *Pigeons and Rabbits:* Mr. W. Cannan, Bradford.

RUSSIAN TRUMPETERS.

"WILTSHIRE RECTOR" has evidently made up his mind that the climate of Great Britain does not agree with the Russian Trumpeters, and is the cause of the difficulty that his friends have found in breeding them. In this I think he is quite mistaken. In my opinion the cause is only that the birds are very much in-bred; and every breeder of experience of short-horns, racehorses, or in short any high-bred stock, knows that the result of close breeding (and all highly-bred animals are more or less in-bred) is increased difficulty in rearing the young stock and occasional sterility of individuals. Also, as Mr. Huie remarks, useless and barren birds are more likely to be disposed of than good stock birds.

I have not the slightest doubt that with patience and a very slight introduction of fresh blood they will breed as satisfactorily as any other high-class variety, more particularly if they are taken in hand by fanciers who are experienced breeders, and who will not show them to death as most of their present owners seem to be doing.—JOHN H. HUTCHINSON.

ENGLISH OWLS.

I MUST ask you to give me a little space for a final word on this subject. Mr. Lyell quotes Euclid, but I fear still his reasoning is not correct. I pointed out to Mr. Lyell the mistake of Mayor in ascribing carelessly to Moore words the latter never wrote. Mayor made a mistake, Mr. Lyell quoted that mistake; both erred from inaccuracy. There, I think, Mr. Lyell should have left the matter, for, a mistake pointed out, its correction ought quietly to be accepted or frankly owned. But Mr. Lyell argues further, saying, "I do not consider Mayor wrong in his quotation about the size of the Owl, for although it is the size of the Turbit that Moore gives as little larger than the Jacobin, he immediately afterwards in the few words devoted to the Owl says, 'This Pigeon is in make and shape like the former (the Turbit). Things equal to the same thing are equal to each other.'" But "make and shape" have nothing definitely to do with size. A little man may be in make and shape like a large man—*e.g.*, he has wide shoulders, or short legs, or a round chest, which may put others in mind of the make and shape of a large man. "He reminds me of So-and-so; he is the same make and shape," anyone may say. A dwarf may in make and shape resemble a giant, being in miniature what the other is in vastness, and the opposite.

Mr. Lyell objects to my theory of climate influencing size; but the Scotch Fantails, smaller than the English, came, I was told, originally from India. This confirms my view. Returning to size, we pretty well know that an Almond Tumbler of olden days was a coarse bird, at least would be so considered now, and even if it had been stated one hundred years since that the Owl was as small as an Almond Tumbler, yet that would not to our ideas be very small. This I see is very well put last week by T. G. Sprunt.

Finally, I will never be a party to writing down the fine-looking, well-flying, bold English Owl. Size, colour, and appearance mark him out as different to the foreign bird, and make its preservation as important to the fancy, particularly the reading part of the fancy, not the "prize-fancier," as any of the older varieties of Pigeons.—WILTSHIRE RECTOR.

MR. DEAN WOLSTENHOLME.

TWENTY-THREE years ago, or in 1852, Mr. Eaton published a set of six matchless engraved coloured portraits, life size, by Wolstenholme—viz., the Almond, Black Mottle, Red Baldhead, Yellow Beard Tumblers, Black Carrier, and Blue-pied English Pouter, and in 1860 he brought out an additional set of six Toy Pigeons—viz., the Barb, Trumpeter, Turbit, Owl, Fantail, and Jacobin, which were also by Mr. Wolstenholme. "As Pigeons matchless," Eaton used to say, and certainly the Carrier has not been beaten by any other picture either before or since; nor has the Almond of the set of six, nor the small one published first in Eaton's "Almond Tumbler" in 1857. Going back still farther I find portraits of bull dogs, and published by Dean Wolstenholme, 6th August, 1834. I find a picture in the Royal Academy catalogue of 1818. It is No. 83 "Portrait of Beach, a favourite bull bitch, bred at Abergavenny, the property of a gentleman, by Dean Wolstenholme, jun.

Mr. Wolstenholme is now seventy-seven years of age, having been born at Waltham Abbey in 1798. He is still painting, and those who, like myself, value pictures connected with their hobbies, in him may meet with one who is able and willing to paint portraits of Pigeons or dogs. He has lately done two for me that are very first-rate indeed. His address is North Hill, Highgate.—J. C. LYELL.

BRITISH BEE-KEEPERS' ASSOCIATION.—This Association held a conversazione in the rooms of the Linnean Society at Burlington House on Wednesday the 5th inst. About seventy ladies and gentlemen were present, and spent an enjoyable evening discussing apiarian matters, and inspecting and criticising the various objects of interest brought for exhibition, among which appeared an ingenious frame-making machine, and a novelty in the shape of liquid wax for cementing on guide combs. Several first-class microscopes with objects living and dead also provided

a share of instructive amusement. The circulation in the larva of the drone bee was exhibited by a member present.

WINTER EXPERIENCE AMONG BEES.

We observe among inquiries addressed to this Journal none more common than those of hapless bee-keepers who have unaccountably either lost altogether the population of hives which were strong in the autumn, or found them so weakened in numbers as to stand a poor chance even of recovery. Your chiefs in the apiarian department are asked to account for accidents of this sort, but too often no satisfactory answer can be given, not merely because a personal diagnosis of the particular case is impossible, without which all attempts at explanation must be more or less guesses in the dark, but because also some of the ills that afflict our apiaries are quite beyond our knowledge and skill to account for.

In my own experience this winter I have been sorely puzzled to explain why two of my best-supplied and most vigorous stocks have been weakened by a most disastrous mortality. In the case of one which had plenty of honey, so great has been the loss of bees, thousands of which I had thrice to remove from the floorboard during the months of February and March, that I thought it gone beyond recovery. The comb and hive (of wood) were perfectly dry and healthy, nor were there any signs of dysentery or other visible disease. I can only suppose that from indolence they allowed themselves to die in the midst of plenty, not having transferred from the sealed honeycombs to their central retreats sufficient food to keep them alive during the prolonged periodic returns of cold or ungenial weather which we had during those months. Those hives I thought absolutely safe, and guessed at every conceivable reason but that which I now believe to be the probable one, till it was too late to save my lamented thousands. The hives are now recovering population, but I can expect little from them this year in the shape of increase. I am now feeding, as they can spare so few for honey-gathering.

All my other stocks save one had been diligently fed quite up to November, and were overflowing with food in the open cells. In the case of none of them was there any extraordinary mortality at the time, or since the above-mentioned were suffering. In fact, I never saw so little damp in any previous winter. Nevertheless my bees are quite a month behind time, even the best of them, owing to the extraordinary dullness and coldness of the weather throughout February and the early weeks of March. And we are now in the full enjoyment of spring with a wonderful display of blossom in our meadows and orchards. Happy they who have strong hives to benefit by it.—B. & W.

ENGLISH AND LIGURIAN BEES.

Much has been written about testing the merits, as honey-gatherers, of the English bee with the Italian Alp or Ligurian bee. This may be very well, but I think scarcely necessary to make a public trial of it. Any bee-keeper individually who keeps both kinds can make the proposed trial for himself privately with far more satisfaction than any public trial would be.

Why need there be this difference of opinion as regards their merits. If anyone does not, or cares not, to keep Italians, why try to write them down? If their colour and beauty are an attraction to some people, independently of their character as workers, by all means let them enjoy them for that. While I cultivate bees for either profit or pleasure I hope to find a place for both kinds. I have yet to learn they are inferior to the English as honey-collectors; in fact, I believe their merits are so evenly balanced that there is nothing to choose between them.—C. F. C., *Hinckley*.

A story is told of a negro in Virginia whose master threatened to give him a flogging if he boiled his eggs hard again. "You rascal!" shouted the enraged planter, "didn't I tell you to cook those eggs soft?" "Yes, massa," said the frightened slave, "an' I got up at two o'clock dis morning, an' biled dem five hours, an' it seems to me I never kin get dese eggs softer.

OUR LETTER BOX.

Dari for Fowls.—Colvile Browne will be glad to hear the opinions of any poultry owners as to the value of "dari" as a food for laying fowls in a confined situation.

Parrot Self-plucked (*D. Judd*).—The only food to be omitted in your Parrot's bill-of-fare are the chilies. Give some lettuce stalks daily; also a daily bath. Put a dish filled with water for the Parrot to bathe in voluntarily, but if the bird will not do so give it a copious shower bath through the rose of a watering pot. Use tepid water.

Feeding Bees (*F. S.*).—It is unnecessary to feed bees when they are working hard ten hours a-day on the fruit trees. Three or four days of such work every week will enable the bees to provide for all the wants of their hives, and breeding will go on rapidly. If the weather change and prevent the bees from gathering honey for some days, it will be wise to give each hive about 1 lb. of sugar made into syrup weekly in small doses. By examining your hives every now and then you may easily ascertain when the bees cover all the combs of their hives. About a week after the combs are covered, nadiring or supering may be resorted to. The book you have referred to will guide you aright in this work of enlarging your hives.

Making an Artificial Swarm (*A Novice*).—Swarming artificially from bar-frame hives is usually done by taking about half the bees and combs from the stocks and placing them in empty hives, not caring much whether the queens go from or remain with the mother hives. As you ask which is the best way of artificial swarming from such hives, we may remind you that in natural swarming the old queens go with swarms, and it is well for the bee-master to follow as near as possible the natural process. Natural swarms go without combs, and it will become a question at some future time whether it is good or bad policy to break up the interior of hives for the sake of placing a few old combs in new hives with young swarms. When your hive is ready for swarming you may remove one bar of worker comb with the queen and about half the bees from it, and put them into another bar-frame hive. If you remove more bars the old hive would be more injured than the new one would be benefited. Indeed, we are of opinion that the best way is to drive a swarm with the queen into an empty hive, and let them fill it with young combs. In prospect of breeding young queens bees invariably build too much drone combs. Empty bars in old and new hives would naturally be filled with too much drone comb while the bees are rearing young queens. If you do not place the old and new hive some feet to the right and left of old stand, place the swarm on it, for the bees more readily enter the old hive.

Hives (*C. G. M.*).—Any one of the dealers in hives who advertise in our columns could supply you.

REMARKS.

5th.—Very hazy at 5 A.M., but clear at 8, and a very fine day.
6th.—Fine morning, rather stormlike at noon, but on the whole a very pleasant day.
7th.—Rain all the morning, fine afternoon, but rain again in the evening.
8th.—Very fine early, but wet morning and night; fine for an hour or two in the afternoon.
9th.—Very bright early, moderately so at 9 A.M., fine by 10, and all day
10th.—Another very bright pleasant day. [bright and pleasant.
11th.—Rather cloudy about 9 A.M., but soon clearing off, and being a very fine day, lunar corona at 9 P.M.

Fine and pleasant week. Temperature much the same as in the previous week, but the nights warmer.—G. J. Symons.

COVENT GARDEN MARKET.—May 12.

A good supply and fair attendance in both Markets. French goods very plentiful, including Cherries and Apricots. Asparagus is quite abundant, both English and Foreign. Another cargo of St. Michael Pines is reported at the wharf, and will be disposed of this week by auction. Lisbon and Maltese Potatoes maintain last week's rates.

From observations taken near London during forty-three years, the average day temperature of the week is 66.6°; and its night temperature 53.3°.

FLOWERING PLANTS FOR HALLS AND CORRIDORS.

HALLS and corridors are not as a rule the best places for plants to thrive in, but nevertheless there is an increasing demand for plants for such places. No proprietor once having his mansion well furnished with flowering plants through the autumn and winter is ever willing afterwards to be without them. He finds that his paintings, his china, and his furniture, be they ever so valuable, do not light up the faces and bring forth the hearty admiration of the majority of his visitors as do the flowers. You must know who is supposed to have employed his pencil on the canvas before you dare admire it as a painting; you must turn a china cup upside down and look at the bottom of it before you can venture to say the top is beautiful, for these things are not judged according to merit, as many would fondly suppose. People who wish to have the credit of possessing a cultivated and refined taste are obliged apparently to admire very often that which, if they asked themselves the plain truth, they can see no beauty whatever in. What a relief, then, to turn to the flowers! All flowers are beautiful, and everybody is supposed to be a judge of them. It is safe even to admire the most hideous combinations of flowers, for there is such an immense margin left here for differences of taste. I have seen hosts of lords and ladies in raptures over those ugly faggots of cut flowers exhibited at our country shows under the names of bouquets and floral designs, and their taste, of course, was never called into question.

By-the-by, how is it that while there is such an immense improvement in vases and epergnes at our country exhibitions, there is little or no improvement in bouquets and nosegays? Is it because the judges are too exclusively local men, and encourage too much their own particular fancies? We meet with different models in different towns and villages, but all the exhibitors in each village appear to have received their lessons in floral decorations in the same school.

To furnish a mansion well and economically with flowering plants during the autumn and winter requires a considerable amount of forethought and management. It is not good policy to use rare and valuable plants for such a purpose, because they are certain to be injured, and likely enough to be killed or rendered worthless for the future. Neither is it good economy to force hard to bring plants into flower in winter when the same plants, or others equally good, if attended to during the preceding summer, would have flowered almost naturally at the time they were wanted.

Many people use principally fine-foliaged plants for house decoration, because, as a rule, they stand rough treatment better than do flowering plants; they last longer, they are easier to grow, and they are nearly always presentable. Flowering plants, on the other hand, are only presentable for a short time; a week or a fortnight in a dark corridor is generally sufficient to spoil their beauty, and there is a difficulty in keeping up a perpetual succession till one gains experience in the work; but in my opinion flowering plants are much more enjoyable in dark cold weather than are foliage plants. There is a refreshing appearance about fine-foliaged plants in the heat of summer; but for dark, damp, chilly autumn give me bright flowers, as they contribute an enlivening effect to which foliage, however fine, can have no real claim.

The difficulties of keeping up a succession of flowering plants are not so great as might appear, but there must be method and arrangement in preparing them. You may grow plants by thousands and then fail if you do not make your arrangements six or twelve months beforehand. It will not do to grow a plant merely because it is beautiful. If it is not suitable for your purpose summon up courage and put it aside, and then utilise the room by growing something more useful, although less beautiful. Many gardeners fail by attempting to do too much. The right course is to find out the special requirements of a place, throw your old loves and special hobbies clean overboard as if they were your greatest enemies, and then take your employer's hobbies and make them your own with all your heart.

I find the simplest way to keep the mansion furnished with plants is to grow but few sorts, and a large quantity of each sort, also those which are of comparative easy growth, and which can be grown good enough for the purpose in one season. I can tell now what will be my principal flowering plants in each month from next August till the following May. Nothing of this kind is left to chance, and much of it is now being prepared for the purpose, consequently there is not much waste of labour or material. In August the principal plants will be—Campanula pyramidalis two varieties, Vallota purpurea forty or fifty plants probably, Lilium auratum and L. punctatum, Balsams, and Fuchsias. These are all very showy, very easily grown, and distinct from the plants in the flower beds. The plants named will form the backbone of the whole arrangement, to which will be added any little odds and ends worthy of associating with them. Campanula pyramidalis lasts good in the house for two months; it might not look so well in a small house, but in our stately apartments it is very imposing.

For the beginning of December, when we aim to have our greatest floral display, the principal plants are Poinsettia pulcherrima, Richardia æthiopica, Gesnera refulgens, Browallia elata, Epiphyllum truncatum and its varieties, Chrysanthemums two or three distinct bright colours, Dendrobium moniliforme, Begonias, Carnations above two hundred one-year-old plants in 10 and 12-inch pots (these are principally for cut flowers), Roman Hyacinths, Primulas, Cyclamens, and Cinerarias. All these flower almost naturally at this time if well grown during the summer. By the end of the month with a little forcing we have the glorious wreaths of little snowballs on the Prunus persica flore-pleno, by the side of which

Deutzia gracilis—beautiful as it is when you see nothing better—looks a dirty white.—WILLIAM TAYLOR.

LATE FIELD POTATOES.

I APPEND my experience both in growing and cooking twelve varieties of late Potatoes; the estimate of the different sorts being derived by actual practice and attentive observation may be useful to some readers. I have had them cooked at various times—from the period of taking up the crop to the present time. I note also their keeping properties, and the degrees that each was afflicted by the disease.

1. *Paterson's Victoria.*—Boils white and floury, a delicious flavour, and a great cropper. It was a little diseased at taking-up time; went no worse as the season advanced. It is a good old variety.

2. *Paterson's Improved Victoria.*—Cooks very white and floury, and is of excellent flavour. It keeps its colour well after being cooked. This is certainly an improvement on the old variety.

3. *Bresee's Prolific.*—Boils white and floury, and of delicate flavour; is a heavy cropper, large and handsome, with tubers of a uniform size. It is one of the best old American varieties, and will retain its character for many years to come as a second early; it was almost free from the disease.

4. *Ashtop Fluke Kidney.*—Cooks white and floury, and is of rich flavour. It is not much of a cropper, being more adapted for a garden, as the haulm is very compact and dwarf.

5. *Red Regent.*—Cooks yellow; pretty good in flavour, and mealy; not much diseased. A good hardy field variety.

6. *White Fluke.*—Boils as white as snow, and floury; it keeps its colour well after being cooked; it is very productive, and but little diseased.

7. *Red Fluke.*—Cooks white, and very floury; a delicious flavour, an abundant cropper, but a good many diseased; it keeps well until late in the season.

8. *Falara.*—Boils white and floury, excellent in flavour, keeps its colour well after being cooked, and is a heavy cropper. It is an excellent field variety, hardy, and very little affected by the disease. My employer is now using it (middle of April) in the house, and it comes to table in fine condition.

9. *Paterson's Albert.*—Cooks as white as snow, is very mealy, and keeps its colour well; it is an immense cropper, almost free from disease; it keeps its colour well after being cooked. It is a good keeper, and cooks as well now as it did the beginning of the year. It will be more extensively grown when better known.

10. *Sutton's Red-skinned Flourball.*—Boils very white and floury, is excellent in flavour, and improves by keeping until now (8th of May); we are using them every day. It is an enormous cropper, proof against the disease, tubers nearly of a uniform size—large, and good for baking.

11. *Late Rose.*—Cooks as white as snow, and very mealy; is of a rich flavour, coming to table in fine condition, and very little diseased. It cooks much better now (middle of April) than at taking-up time. It is one of the finest American late varieties yet sent out.

12. *Sutton's Hundredfold Fluke.*—Boils white and floury, and is of fine flavour. It is one of the very best late varieties at this season of the year. At taking-up time it boiled very close and waxy, but was still good in flavour. It is an enormous cropper, and free from disease.—W. MCPHERSON, *The Gardens, Snelston Hall.*

PROPAGATING COPROSMA BAUERIANA VARIEGATA.

THE above plant being considered by some rather difficult to strike, perhaps the following remarks as to how we have struck a large batch this spring may be useful to those who desire to increase their stock and have not succeeded. We lifted our old plants from the flower garden late last October, potted them, and put them in a close frame until established, then wintered them in a cool fruit house, and placed them in a temperature of about 60° in February for a fortnight before taking off the cuttings.

We use shallow saucers for these and all softwooded bedding plants, except Geraniums, in spring propagation; our present stock was what are commonly used for Strawberry forcing, with a hole in the centre for drainage. The compost used is the ordinary one of loam, leaf soil, and sand. We dibble about thirty cuttings in a pan, and out of a large batch put in thus and plunged to the rim in a bottom heat of about 80° in an ordinary lean-to pit, not 10 per cent. missed, being fit to pot off in a month. We find autumn propagation does not succeed.

The Coprosma is in its best dress in the dull wet days of autumn, and may be left out until November. A few large plants lifted and wintered as above will furnish many cuttings in spring after having been turned to account for room and general decorative purposes in the winter.—H. J. C., *Grimston.*

HOLLY BERRIES FOR CHRISTMAS.

PERHAPS at this season of the year the Holly is seldom thought of, but as the festive season of Christmas draws near its berries are in great request, and but few homes are then considered furnished without the Holly and Mistletoe. These berries are prized from the palace down to the cottage, but of late years there has been a great scarcity of Holly berries. I think this is a subject worth inquiring into at the present time, for this is the month when the Holly is usually in bloom.

My opinion is that if we could pay more attention to the Holly at the time of its blooming and fruit-swelling period we should find more Holly berries in the right places, and at the time they are especially coveted.

It is often a disappointment to have fine Holly bushes but no fruit, for everyone will admit they are of great beauty when well laden with brilliant berries. It is well known that the Holly is a very thirsty shrub and a gross feeder, and when in active growth will absorb large supplies of water. I think I shall be able to show that the scarcity of Holly berries, in many instances, has been caused by dryness at the roots during the summer months. My remarks apply chiefly to Hollies grown on hot sandy soils with a gravelly subsoil. On such soils, where Holly berries are in request, they will well repay a little extra attention. This is not mere theory, but is proved from actual practice.

Last year I tried the experiment on eight pyramidal Hollies of the gold and silver Queen varieties. The watering was commenced when they were in bloom and continued through the summer months, the plants being watered about twice a-week, not in mere dribblets, but they were given thorough soakings. These Hollies were planted on grass, but not grassed quite up to the stems, but instead were dressed with well-rotted manure, and a sprinkling of soil put on the top to prevent drying and to produce a neat appearance. The frequent waterings on the surface washed down the manure to the roots. It is astonishing what a little manure will do applied as I have stated; but where it is not practicable to apply manure in a solid state, liquid manure may be used with advantage, but not given in too strong doses.

If there are any favourite Hollies growing on grassy mounds or on slopes, then there will be a little difficulty in applying water, but this can be overcome. I will give as an example a plant on a grassy mound. In this case have three or four flower pots of convenient size, and sink these around the tree at convenient distances, but not nearer than a foot to the stem, and not too deep, say 3 to 4 inches, the pots to be placed perfectly level, then all will be ready for the watering. As a matter of course the hole in the bottom of the pot must be open. Fill them up to the rim, and the water will then gradually filter through and find its way to the roots.

In the case of sloping banks the same plan will do with a little variation—that is, by placing the pots on the upper or higher side of the trees. If these pots are filled with water two or three times a-week during the flowering and fruiting season I think there will be no cause to complain of a little extra labour. I may mention that scores of trees that were not treated in the way described were quite barren. I have said that when solid manure cannot be applied liquid manure will be beneficial. I know some people will object to strong liquids owing to disagreeable smells, but there are many kinds of manure which are readily dissolved and leave no unpleasant odour afterwards. I know of no manure so easily applied and so effectual as guano when it can be had really good. I would add an ordinary handful to every four gallons of water; it might be applied stronger, but it is best to err on the safe side. In mixing it will be necessary to stir it well before using. Those who have the convenience to mix up larger quantities will find it less trouble. Many shrubs and plants would be benefited by such applications, such as Skimmia japonica and Pyracantha, even wall fruits and trees on dry

parched borders. The plan well carried out will result in a beautiful crop of Holly berries.

But after all the birds may enjoy the berries, for when winterly weather sets in hunger is a sharp thorn, and they will soon clear a Holly tree of its fruit. The fieldfares are very destructive to Holly berries, for coming as they do in flocks they will soon clear a tree. The Mistletoe thrush is also a very troublesome bird in sharp weather, so that those who have berries and prize them will do well to be on the look-out and protect them before it is too late. Nets will do put carefully round, but I adopted the following plan last year: I had some balls of white worsted and run it all round the heads of the trees where they were not too large. It is easily and quickly done by just twisting it round the tops of the shoots or round the leaves. This was the only thing that saved us berries for Christmas decoration.—G. R. Allis.

DIOSMA (ADENANDRA) UNIFLORA.

The Diosmas are a genus of beautiful Heath-like shrubs from the Cape of Good Hope. They are of easy culture, vary-

Fig. 93.—Diosma (Adenandra) uniflora.

ing in height of from 1 to 4 feet, are graceful, yet compact in habit, and are exceedingly floriferous. The colours of the flowers are mainly white, or white and pink; the plants afford nice sprays for cutting, which they endure without injury. Those who enjoy hardwooded greenhouse plants which do not require the nice attention and skilful management of Heaths would do well to turn to the Diosmas.

Besides being of elegant appearance by their Heath-like foliage and attractive by their multitude of star-like flowers, the plant, like other Rueworts, emit a powerful perfume. From this characteristic is their name derived—viz., from *dios*, divine, and *osme*, odour. These plants are not extensively cultivated, probably because they are less showy than the usual class of summer greenhouse plants which are now in repute, yet they possess a sober quiet beauty which should, irrespective of their perfume, entitle them to more general cultivation. They are readily propagated by cuttings in sand under a bell-glass, and do not require much heat or they will elongate instead of emit roots. When rooted they should be potted in peaty soil and be grown in a light intermediate house, duly pinching the shoots to keep the plants compact and bushy. They should be shifted-on as required, not large shifts at a time, and be potted firmly, incorporating, as the plants become large, loam and charcoal with the peat. The shoots should not be pinched after August, but the plants should then be stood in the full sun, shading the pots, to have the wood matured, and every shoot will bristle with bloom in the following spring and early summer. When the plants have flowered they should be pruned, top-dressed, and encouraged to make fresh growth to be well matured before winter. The plants may be wintered in any light structure from which frost is excluded, but it is desirable the temperature do not fall below 40°.

The more showy of the species now form new genera, Agathosma, Baryosma, Adenandra, &c., the one figured belonging to the genus last-named. It is a dwarf-growing species with pink flowers, and worthy a place in any collection of hard-wooded greenhouse plants.

POINSETTIA PULCHERRIMA.

Probably most cultivators of this brilliant winter plant have their Poinsettias freely growing now. They were shaken out some time ago, repotted, and are on shelves in some well-heated structure making rapid growth preparatory to large and highly coloured whorls of bracts to set the houses aglow at Christmas time. Where fine heads are required irrespective of length of stem the plants cannot well be started too early, provided that conveniences are at hand for growing them on without check. When started early two conditions are essential to success—the plants must have heat sufficient to keep them healthy, and light to keep them as sturdy as is consistent with their nature. Not in all places where Poinsettias are required can these conditions be found. There may be heat but not light, and as a consequence the plants become drawn. By this cause are many failures, or at the best partial successes. A stove, it may be, is provided in which to flower the plants; but this structure, being devoted to Ferns and foliage plants in the summer, requires to be shaded, and the other houses which afford the requisite heat are vineries, and their roofs are covered with foliage. But still those who have a stove in which a night temperature of 60° is kept up in winter expect to have Poinsettias, whether there is any suitable place for growing them in summer or not. Certainly a shaded stove or fernery is not suitable, neither is the vinery which is darkened by foliage. Now with these, and only these, conveniences—a shaded stove and vinery in which to prepare Poinsettias, the best plan to adopt is to defer starting the plants until late in the spring—*i.e.*, about the second week in May, and instead of growing them in shaded houses prepare the plants in light frames.

Frames usually known as "cold" are really—or may be made so—admirable miniature stoves in summer if the sun heat is carefully conserved and moisture afforded to make the atmosphere genial. These are very suitable in which to grow Poinsettias during the months of June, July, August and September. This free, healthy, unchecked growth for four months is sufficient to prepare valuable decorative plants for winter effect. They may not be large or tall, but if they are healthy, dwarf, and have heads 6 to 8 inches in diameter, they will be exceedingly useful and attractive, and for many purposes indispensable. By starting the plants late it is seen their culture is greatly simplified, and the only structures necessary are a warm house in which to bloom them in winter, and plain frames or pits in which to grow them in summer.

My first essays in Poinsettia-growing were failures. I started my plants early, and could only grow them on under the shade of Vines, and hence their growth became weak and elongated. By starting later and growing mostly in frames a fair share of success followed. I never had nicer, more useful and showy plants, than the year in which I cut the plants down on May the 20th. They were cut hard in and the plants stood in the vinery to break; when pushed half an inch they were shaken out and repotted, and kept in the vinery a week to assist them to become re-established, and were placed in cold (now sun-warmed) frames on June 22nd.

On being shaken out the plants were potted in clean pots—that is important—a size smaller than those in which they had bloomed the previous year. The soil used was equal parts of loam, peat, and leaf mould, with a free admixture of silver sand. Towards the end of July the pots were filled with active roots and the plants were shifted into their blooming pots, using soil considerably richer by substituting

cow manure for the leaf mould and diminishing the proportion of peat. In this final potting mixture lumpy charcoal was freely incorporated and the pots were well drained, for although Poinsettias require copious supplies of water, any approach to stagnancy must be avoided. The foliage will turn yellow and drop off either by drought or excessive wet; therefore both extremes must be provided against, as by losing their leaves the plants are robbed of half their beauty. In potting it is well not to fill the pots within 1½ or 2 inches of the top; and then, when the bracts, show a top-dressing of cow manure can be given, which will increase their size and colour. The routine culture in frames is attention to air and watering. In bright weather water must be used freely to supply the loss by transpiration from the large leaves. In the afternoon, at closing time, the plants should be freely sprinkled overhead. Always use tepid water. In sultry weather the removal of the lights at night is very beneficial. The plants so treated attained a height of 2 feet and perfected good heads. It is important that they be removed from the frames when the night temperature falls below 60°. Care must be taken that they are not placed suddenly in a dry atmosphere, or the foliage will inevitably turn yellow and decay. Any check to the roots by whatever cause is also a certain precursor of bad foliage, or none at all.

For dwarf plants I strike young shoots in summer. These small plants are after all the most useful. They may be had from 4 inches high to 1 foot, and are invaluable for many purposes of decoration. Propagation is also effected by the old wood somewhat after the manner of Vine eyes, but for dwarf healthy plants I have always found the striking of the young shoots the most satisfactory. The cuttings may be put in any time during the summer. If plants a foot high are wanted the end of July is a good time, and for very dwarf plants a month later will be a suitable time to take the cuttings. With due care and attention not one in twenty will fail to strike. The conditions are brisk heat, a close atmosphere, and, for a time, dense shade. For striking the cuttings a bottom heat of 90° is not too much. This may be afforded by fermenting manure, on which is placed close-fitting handlights or a frame —that is, in case no proper propagating house is at hand.

The cuttings should be selected from stout short-jointed shoots and be inserted singly in thumb pots, using light soil surfaced with pure sand. They should be laid for half an hour, or less, to dry the wound previous to being put in. For the first few days they must be densely shaded, gradually inuring them to the light. In ten days the young roots will protrude through the pots, and the plants can, after being duly prepared, be shifted into their blooming pots, having one or several plants in a pot as desired. These cuttings if well managed will not lose a single leaf, and the bracts they produce will be as fine as if the cuttings had not been severed from the plants. Long-jointed sappy growth will not strike, but select those shoots with the leaves near together, and take them off at a time when the stems have attained a dark green and become mature, and they will strike freely. Indeed few will fail.

Thus with plain homely materials and starting late may a supply of these attractive plants be had. So long as a properly heated structure is provided in which they can bloom their summer culture need not be a source of trouble. Cold frames transformed into miniature stoves by conserving the sun heat, and cuttings of the young shoots being put-in in the growing season will result in a stock of admirable plants to brighten up the dark winter months. The glowing heads will last for weeks either on the plants, or cut and inserted in moist sand for using as cut flowers in rooms.

For this plant there is no substitute, and I advise all who have the means of growing them to increase their stock by the striking of cuttings as fast as they can be obtained, still waiting until each shoot is stout and in a measure matured before it is severed from the plant; success is then certain with correct treatment and attentive care.—A Surrey Gardener.

OVERCROWDING OF PLANTS AT EXHIBITIONS.

In Mr. Tymon's notes on the Manchester Auricula Exhibition is a sentence demanding prominence at the present time. The sentence is this—"The plants looked huddled up, and it was nearly impossible to make out what plants belonged to any one exhibitor." That is an evil common to most exhibitions metropolitan and provincial, and, moreover, it is a growing evil. The good old plan of dividing collections by strips of list is being generally departed from, to the no small confusion of visitors and causing unpleasant crowding, as each examiner is often obliged to stop to count the plants, and, as well as he can, determine for himself where one collection ends and the next begins. By less crowding and clearly-defined divisional lines the groups of plants would show to better advantage, and the exhibitions would be much more enjoyable to the general public.—Ex-Exhibitor.

THE ROYAL HORTICULTURAL SOCIETY.

The present state of the affairs of the Royal Horticultural Society is most bewildering. Who could ever have imagined that a Society of so long standing, so honoured at home and abroad, and privileged with the title of "Royal," could have fallen so low as that it should be sued for the payment of the prizes it voluntarily offered and which it is unable to pay? There is a heavy responsibility resting on the shoulders of those men who were instrumental in turning out the old Council, and who came before the Fellows with bland speeches and promises which have never been fulfilled. They and their nominees now on the Council are answerable for all this, and if they have any sense of honour they will acknowledge their fault, and resign a position they never ought to have held, and which they are unable now to hold with credit to themselves and with advantage to the Society. In these remarks it must be understood that we except those gentlemen who were nominated and accepted office as representatives of horticulture, but who it is well known have been overruled and all but ignored in all the negotiations that have been carried on between the Council and the Royal Commissioners. It is true that lately since the crisis is come and their help has been needed, they have been shown more consideration; but the mischief is done, and let those who have caused it bear the responsibility. Every official position in the Council since that calamitous day when the old Council unfortunately resigned has been filled with a Kensingtonian Fellow. President, Vice-Presidents, Secretary, and Treasurer were all Kensingtonians till a month or two ago when trouble was at the door, and then, for decency sake probably, the Hon. and Rev. J. T. Boscawen was made a Vice-President, and that was the first compliment paid to a horticultural member of Council. It cannot be said, therefore, that the present difficulties were brought about by a horticultural Council, of which one would suppose a horticultural society ought to be composed.

But what is to be done? The men in power seem helpless, and have no remedy to propose. It is high time the Fellows took the matter in their own hands. Why should not a committee be appointed to confer with the Council, and act in unison with them in negotiating with the Royal Commissioners, or even to approach the Commissioners themselves? Let this be composed of earnest business men with a love of horticulture in their hearts, and imbued with the spirit and traditions of the Society. Let them not be of those fussy partisans who lately have shown themselves so prominently at the Society's meetings—such men, for instance, as complain of the Secretary's neglect of duty, and when appealed to have mistaken the wrong man for the Secretary—of such as puts himself forward so prominently that an inexperienced Council make him an Auditor of the Society, in which capacity he so egregiously fails as to pass accounts as paid which never have been paid, and of which he could never have seen the vouchers. It is not such men who are to form such a committee.

Another step might be taken which would help to mend matters. Let there be a committee nominated to make a house-to-house visitation over the whole of the South Kensington estate and solicit subscriptions and donations to enable the Society to meet its present difficulties. Some such course must be taken or the Society must lapse. But first of all let us see a strong Council of men in whom the Society can have confidence—men with statesman-like views, who can and will grapple with the present difficulties. Until we have such a Council there is no hope, let whatever may be done by Royal Commissioners or the public, that the Society will or can go on.

PREVENTING GREEN FLY.

Your correspondent ("Constant Reader") on orchard-house management in your last number, May 13th, suggests instant fumigation on the first appearance of aphis. I find that prevention is better than cure, and with the exception of this year (I was without tobacco rope at the proper time) when

I was troubled a little with green fly, I (my gardener) always have fumigated before the trees came into bloom, whether there was any appearance of fly or not—I may say when there was no appearance—and have never suffered from it for many years. I select a calm evening and fumigate a second time, or the second or third succeeding evening.—A THIRTEEN-YEARS SUBSCRIBER.

MANCHESTER HORTICULTURAL EXHIBITION.

WHILE in the metropolis horticulture seems to be in a moribund condition, and everything at what ought to be its head quarters seems to be in hopeless confusion, it is a happy thing that in the provinces all seems reversed. The great provincial shows of the north of England at any rate show no diminution of interest or lack of support; nay, rather increased vigour seems to be the rule with them. No greater contrast could possibly be afforded than that which I was witness to at South Kensington on Wednesday last and Manchester on Friday. As one looked into that miserable arcade and saw not an exhibition of pot Roses or Azaleas as announced, but a wretched lot of things occupying about one-half of one arcade, and heard exasperated visitors asking, "Where is the show of pot Roses?" the only redeeming point being the herbaceous plants; and then looked down that grand tent at Manchester filled with examples of skill which have never been surpassed, or saw the banks of Orchids and stove and greenhouse plants in the great conservatory, and then caught a glimpse of the long lines of carriages waiting outside the gates, one could not help (as more than one person observed afterwards) being reminded of the long-past glories of the Chiswick Shows. The weather was lovely beyond all precedent for a Manchester Whitsuntide. For the last eight years the opening day has been ushered in with rain, but on Friday last we were in July with a soft balmy air and a brilliant sun, the gardens fresh in the loveliness of early spring, and everything "couleur de rose."

The interest of the prize list is not so great, of course, to those who live at a distance as to those who are closer at hand, but when I say that amongst amateurs Dr. Ainsworth, Mr. Wrigley, Mr. Shuttleworth, Mr. Stevenson, &c.; and amongst nurserymen Messrs. Paul & Son of Cheshunt, Mr. Turner of Slough, Mr. Williams of Holloway, Mr. Standish of Bagshot, Messrs. Rollisson of Tooting, Mr. Jackman of Woking, came into competition with the Messrs. Coles, Mr. Rylance, Mr. Cypher, the Messrs. Yates, and others who may be looked upon as local exhibitors, those at a distance will readily believe that there was an abundance of good material to make up a grand show.

Fierce was the competition for the premier prize for pot Roses (£25), carried off after close grappling by Mr. Charles Turner of Slough, Messrs. Paul & Son taking second place. We may, perhaps, have seen as fine specimens in London, notably last year at South Kensington, but Manchester never saw such pot Roses, and these two great growers certainly never excelled the plants exhibited. Mr. Turner had grand examples of Céline Forestier, Souvenir d'un Ami, Victor Verdier, Paul Perras, Beauty of Waltham, and Charles Lawson; while in the Messrs. Paul's collection the following were especially grand:—Victor Verdier, Camille Bernardin, Horace Vernet, Souvenir d'un Ami, Princess Mary of Cambridge, and Madame Victor Verdier. In the collection for twenty Roses in 8-inch pots the order was reversed, Messrs. Paul & Son being placed first, and Mr. Turner second. And here let me say, that in the opinion of some of the best rosarians in the kingdom the most beautiful Rose in the two collections was (hear ye that, Messrs. Camm and others, who rated me for praising it last year!), Madame Lacharme. I shall watch with interest how she behaves later on, but as a pot Rose she is a long way ahead of all the white Roses we have.

But grand as these large Roses were as examples of cultural skill, I do not think that they bore in this respect any comparison with the exotic Ferns, more especially the Gleichenias exhibited by that enthusiastic grower Mr. Shuttleworth of Preston. One has been accustomed to see the Gleichenias as exhibited by Mr. Baines, Mr. Williams, and others, but such examples were never shown as those in Mr. Shuttleworth's collection to-day. The collection of eight comprised Gleichenia speluncæ, rupestris, and flabellata; Cyathea medullaris, Dregei, and princeps, Davallia elegans, and Leucostegia immersa. Nor were his collections of Adiantums less meritorious, consisting of Farleyense, cuneatum, assimile, tenerum, formosum, and a most striking form of Adiantum capillus-Veneris raised by his sister-in-law, and called after her, Dawsoni. The pinnæ were very large, and altogether the plant very remarkable. Mr. Wrigley had also a fine collection of exotic Ferns.

Two collections of Clematises were exhibited by Messrs. Standish and Jackman, the latter being one of great beauty. It comprised Countess of Loudoun, rubella, velutina purpurea, lanuginosa candida, Thomas Moore, Jackmanni, Mrs. J. Bateman, Alexandra, and several seedlings. Rhododendrons were finely exhibited by Mr. Standish and Messrs. Yates, some of very fine quality being staged by the former gentleman; and some very nice collections of herbaceous plants came from Messrs. Rollisson of Tooting, and Mr. Yates of Sale.

The Azaleas were, some of them at least, very fine, although the backwardness of the season had hindered many of them from being sufficiently in bloom, but the collection shown by Mr. Turner of Slough, of twenty varieties in small pots, was exceedingly beautiful. The plants were small but symmetrical, and completely covered with bloom, and amongst them were the following kinds:—Madame Alex. Hardy, Duchesse de Nassau, Prince Albert, Apollo, a truly grand flower; Flag of Truce, Reine des fleurs, Stella, Mademoiselle Marie Van Houtte, Duc de Nassau, and Eugène Mazel. The Belgian varieties evidently both for size and colour are beating our English-raised varieties out of the field.

The Pelargoniums, Calceolarias, Gloxinias, &c., call for no special remark; indeed they were the weak point of the Show, and, except the collections exhibited by Mr. Rylance, were not possessed of any merit. Having indicated the most remarkable productions in the large tent, I now pass on to notice the great wealth of beauty and rarity contained in the great conservatory.

Certainly those who want to see exhibitions of Orchids must now go to Manchester, for nowhere do we find collected together such exhibitions as at this Whitsuntide Show. Dr. Ainsworth, Mr. O. Wrigley, Mr. Broome, Mr. Leech, Mr. Taylor amongst amateurs; and Mr. Williams of Holloway, Mr. Yates, and Messrs. Rollisson, nurserymen, all contributing grand collections and specimens. Amongst those sent by Mr. Wrigley were grand masses of Masdevallias, such as I have nowhere else seen, comprising Lindeni, Harryana, ignea, ignea gigantea—these weird-looking Orchids were unknown to growers in those long-past days of Chiswick. He had also Odontoglossum Roezli and Roezli purpurea, rare and beautiful, the lovely O. vexillarium in fine health, Saccolabium ampullaceum, &c. In Dr. Ainsworth's collection I noticed grand plants of Vanda suavis, Phalænopsis grandiflora, and Phalænopsis grandiflora aurea with more intense golden lip, the rare and beautiful Dendrobium Wardianum, the yellow Anguloa Clowesii, Oncidium sphacelatum (a grand mass), Odontoglossum Alexandræ, Lælia purpurata, and Cattleya Mossiæ. Mr. Broome had fine plants of Dendrobium Bensoniæ, Cattleya Mendeli (very beautiful), Phalænopsis Lüddemaniana. Amongst Mr. Williams's plants were fine examples of Oncidium Inteo-purpureum, Cypripedium caudatum and villosum, Aërides Veitchii and Fieldingi, and Dendrobium densiflorum.

The collections of stove and greenhouse plants shown by Messrs. Cole & Son, Mr. Rollisson of Tooting, Mr. Cypher, Mr. Shuttleworth, Mr. Stevenson, and Mr. Samson, were all that could be wished for; Messrs. Cole & Son taking, as they ever do, the foremost place. Amongst their plants were grand specimens of Azaleas Conqueror, Iveryana, and Duc de Nassau; Pimelea mirabilis, Cycas revoluta, Cocos Weddelliana, Statice profusa, Anthurium Scherzerianum, Clerodendron Balfouri, Genetyllis tulipifera, Erica Cavendishii, Epacris grandiflora, and Bougainvillea glabra.

One never sees anywhere such collections of boxes of cut blooms as at Manchester, nor such tastefully arranged bouquets. Messrs. Cole exhibited in the former class a very beautiful box containing Phaius Wallichii, Musa coccinea (most brilliant), Ixora coccinea, Cypripedium caudatum, Ixora princeps, Cattleya Mossiæ, Erica ampullacea obbata, Aphelexis macrantha purpurea, and other choice blooms. The bouquets exhibited by Mr. Cypher of Cheltenham, Messrs. Turner of Liverpool, and Mr. Rylauce were very good—indeed I question very much whether we ever see in London flowers so tastefully arranged.

Besides the exhibits in the tent and conservatory, of which we have recorded the most remarkable features, the ground outside was filled with greenhouses, boilers, and various contrivances connected with horticulture, including samples even of peat, &c., exhibited by Mr. Epps of Lewisham, worthy, indeed, of the attention of Manchester, where so much is used for Orchid-growing. There was also one tent devoted to what we call art in connection with horticulture, containing some of the very choicest productions of English and foreign manufacture in glass and china for all matters pertaining to fruit and flowers. Here were vases and cachepots from Leucojes, the royal factories at Berlin and Dresden; majolica dishes from Minton; vases, jardinières, &c., from Worcester, and some of the choicest and as yet unsurpassed glass from Webb of Stourbridge. Many of these were filled with some of the most beautiful imitations of flowers from some of the most eminent French artificial flower manufacturers, which might deceive even experienced growers.

Manchester is never behindhand on these occasions in the hospitality she shows to those who are resolved to assist as judges and exhibitors, and as usual there was a dinner at the "Old Trafford Hotel."

Mr. Leo. H. Grindon, in proposing the health of the exhibitors, said that the present was one of the grandest shows that had ever been held in Manchester. There were more good plants exhibited that day, taking the total, than they ever had before.

Mr. T. M. Shuttleworth of Preston, whose name was associated

with the toast, said that he had no hesitation in saying that the Show they had seen that day was the finest that had ever been seen in England. London could not approach to it.

Mr. Williams and Mr. Wills returned thanks on behalf of the nurserymen.

Mr. G. Paul proposed the health of the Judges, which was responded to by the Rev. H. Dombrain.

"Success to the Manchester Botanical and Horticultural Society" was proposed by Mr. W. Paul, and warmly responded to.

AMERICAN ALOE'S RAPID GROWTH.

It is not unusual in the small island of Guernsey to see fine specimens of the Agave americana, commonly called American Aloe, from thirty to forty years old, throw up a flower spike of nearly as many feet in the space of a few weeks' time. There is one still standing on the property where I am gardener, which flowered in the autumn of 1873, growing at the rate of 6 inches per day during three weeks.

It commenced flowering the first week of September. About the 10th I took the actual measurement and found it stood 12 feet 6 inches high, and in exactly twenty-one days more it measured 23 feet. The scape now measures 25 feet in height, and 25 inches in circumference at 5 feet from the ground, where it starts up from amongst the numerous large fleshy leaves, about fifty in number, each measuring 8 to 10 inches across and 6 to 7 feet long. The leaves are now almost withered and dilapidated, but before flowering the plant was 12½ feet in diameter and 8 feet high.

From strict inquiries I understand it to be now about thirty-eight years old, But four years ago a similar one flowered in this locality, which stood, I am told, 35 feet high. The flowers of the present plant opened freely and showed their yellow anthers to great advantage, trembling with the slightest wind, but no seeds have ripened.

What I found remarkable was, a number of small offsets flowering last year round the base of the old plant. This Aloe, and two others equally large, which I daresay will soon flower also, have been planted in their present positions in 1872, under the able instructions of Mons. André, during the formation of one of the beautiful *parcs* of which he is the originator in Guernsey, and which will long remain as a souvenir of his genius.—J. J. G.

"WATER-CREASES!"

Farringdon Market at four o'clock in the morning was a curious sight. As many as twenty enormous railway vans, laden with baskets of Water-cresses piled tier above tier, blocked up the street leading from the main thoroughfare. The hampers were being rapidly distributed along two rows of stalls, close to the market-gates, which were thronged by such a collection of men, women, and children as I had never seen except in Seven Dials on Saturday night, or in Kentish Hop fields at the time of the picking. Nine-tenths were Irish, and the chaffering all along the line was proportionately lively. The sales varied in amount from the modest four-penn'orth doled out by the handful to the five pounds' worth which was carried to the go-cart of the flourishing greengrocer. For the most part, however, a sum of four to five shillings was invested by the hawker or hawkeress, but few parted with their money without a considerable amount of bargaining. The "creases" were packed in little hampers in four separate layers, and there was often a keen competition for particular "middles" or "sides" (*i.e.*, for the layers occupying those places in the hampers), which to a practised eye appeared to be especially tightly compressed. As to the coarseness or fineness of the plants, too, much connoisseurship was called into play. "Just look at them middles," said a dealer: "why, they're so tender as your grandmother, without any teeth, 'nd be glad to eat 'em." "Keep? They'll keep till Sunday morning, and parties comin' out o' chapel 'll be glad to take 'em home to dinner." One magnificent specimen of an old Irishwoman enlivened the proceedings with much jocular comment, interspersed with queer scraps of old verse, before she walked off with a huge basket of "creases" that even a Swiss porter would have found rather heavy. With long white hair, with eyes of the lightest blue that Tipperary ever produced, with a complexion that needed no adventitious colouring, with a bright-red shawl, and a coarse stuff dress looped up over tremendous boots, she was as picturesque an object as one often sees. Presently there came tripping through the big iron gates a couple of little children, evidently brother and sister, who proceeded to trade with the most business-like air. "One middle and a side" were what they wanted, and it was curious to see how cleverly they beat down the price from 2*s.* 6*d.* to 1*s.* 10*d.* The little girl did not seem to be more than ten or eleven, and her brother was at least a couple of years younger; but even at that age they were alone in the world, earning their own livelihood. They had, as I learnt, no father, no mother, no relations at all; they rented, for 1*s.* 6*d.* a-week, a room in a court near Drury-lane; and here they were, looking tolerably tidy and clean, laying in their stock-in-trade for the day. The dealer, an old woman, who was too fat not to be good-natured, confided to me that she had let them have the "creases" for 2*d.* less than she had just been offered. "Them kids is wonders," she observed, "and most of us is pretty easy with them."

Water-cresses, I learnt, are about the best paying of all vegetables to hawk about the streets, for the profit is rather more than 100 per cent.; so the "kids" would make about 2*s.* for their day's work, provided they could sell off their whole stock; and this they generally succeeded in doing. "Why, there's people as 'ud give them children tuppence for a bunch as they'd grudge a penny for to you or me," said the old lady; and I must admit that if I ever go into partnership with the speaker in the Watercress line, then we shall have no chance against the two brats if the interesting appearance of the sellers is to be an element in the business.

Most of the Watercresses, it seems, are sold in poor neighbourhoods. Cabmen, railway porters, and 'busmen are all good customers, and a regular trade is also driven among the lodging-houses at Highbury and Hoxton, where the German clerks live, and in some of the foreign quarters about Soho. At the West-end the householders are above buying from costermongers, and order their "creases" from their greengrocer. One club in Pall Mall buys from an old Irishwoman who has supplied it for the last twenty years, but this is a solitary exception. In parts of the slums of Westminster there is a large demand, for there is a wide-spread belief among the poorest classes that there is nothing so good as "creases" to purify the blood. My informant had known them cure a man whom she described as "spotty all over," when even Holloway's pills had failed, and the force of panegyric could go no further. "Farndon," it appears, is not open on Sunday morning, being under the control of the Corporation of London; and on that day the market is held in the Seven Dials, but the "creases" sold there are mostly those brought to London on Saturday morning, and not disposed of on that day.

They are grown in all parts of the country. Liphook in Hampshire, Springhead in Kent, the Valley of the Thames above Reading, and that of the Kennet beyond Newbury, furnish a large proportion of the daily supply; and a clever cultivator who knows how to humour his crop with the water and the mud that they like finds the business very profitable. —(*Morning Post.*)

PRIMULA CORTUSOIDES AMŒNA HARDY.

Seeing in one of your late numbers a doubt as to the hardiness of Primula cortusoides amœna, I think you may like to know that I removed a bed of them, and also one of P. cortusoides, from a south border to one facing north after the bloom was over last summer. Here they were forgotten, and when I wished to put them into shelter for the winter I could not find them, the plants having all died down. I made up my mind I should never see them again, but this spring they came up vigorously.

The P. cortusoides is now in full flower, but the P. c. amœna, though in vigorous leaf, shows no sign of flowering. Having survived the late severe winter in the neighbourhood of York, proves it to be tolerably hardy.—P. M.

Royal Horticultural Society.—The meeting of the Scientific, Fruit, and Floral Committees fixed for 26th inst. has been postponed on account of that day being Derby day. The next meeting of these Committees will take place on Wednesday, June 2nd.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Dichorisandra Saundersii. *Nat. ord.*, Commelinaceæ. *Linn.*, Hexandria Monogynia. Flowers white, broadly edged with blue.—"Introduced from Brazil by W. Wilson Saunders, Esq., F.R.S., and given by him to Kew, where it flowered in

July, 1873; it forms a pretty stove plant about 3 feet high."—(*Bot. Mag.*, *t.* 6165.)

The French Paradise Apple (*Pommier de Paradis*).—"The French Paradise stock is of spreading habit, with purplish shoots. The inflorescence is abundant, and precocious as to season, and also in relation to the age of the plant. The young leaves are glabrescent, oblong-lanceolate, the apex acute, the base rounded, the margin crenulated, the crenulations mucronulate; the petiole is less than half the length of the leaf, setose, and the stipules are linear-subulate, as long as the petiole. The peduncles are about three-quarters of an inch long, setose; the flower-tube glabrous, urceolate, reddish, one-eighth of an inch long; the calyx-lobes triangular, gradually acuminate, setose within; the petals concave, oblong, obtuse, tapering at the base into a short stalk, and provided with a few cottony hairs on the inner surface; the styles are crested at the base for a short distance, and there slightly covered with cottony hairs, dividing above into five stigmatic branches.

"The fruit, which is a really good early eating Apple, is, according to our notes, of medium size, oblate, somewhat angular, yellow, changing on the exposed side to deep golden-yellow, and sometimes having a thin flush of rosy red. The eye is broad, but closed, sunk in a rather deep cavity. The stalk is short, scarcely projecting from the hollow, which is not so deep as that of the eye. The flesh is pale straw colour, fine-grained, solid, juicy, and with a brisk agreeable flavour. It ripens in the middle and end of August, and would form a good useful early dessert Apple, independent of its value as a dwarfing stock for Apple trees grown in the bush or pyramidal form."—(*Florist and Pomologist*, 3 s., viii., 97.)

CELOSIA PYRAMIDALIS.

For the decoration of greenhouses or conservatories during the late summer and autumn months the Celosia pyramidalis aurea and coccinea are enduring and beautiful, and are well deserving extensive culture. The habit is pyramidal, branched or feathered, and the height depends upon the culture. High culture produces plants 2½ to 3 or 4 feet in height; small pots and high feeding produces very much dwarfer plants; and starving treatment results in smaller plants which not unfrequently, from their fine feathery habit, are fully as useful as those which have been more liberally treated. The varieties vary considerably in the mode of growth, though the pyramidal form is maintained in most plants, but some branch very near the base and are grandly feathered to the summit, the branchlets arching over with much grace and elegance. These are the most beautiful. The tasselled forms are heavier in appearance, being a combination of coarse feathers and small cockscombs. In colour too they also vary considerably, pink, rose, crimson, scarlet, orange, yellow, and all the various shades of those colours. Some plants in a young state are apt to show a small comb, and the impression is given that the strain is a bad one, and under the impulse of the moment the plants are thrown away. That is too hasty judgment. Celosia pyramidalis is a broken Cockscomb, and a premature comb is not an evidence of bad strain, but we can hardly say it shows a good one; yet if the small precocious combs are pinched out, and the plants are grown on, the plants and quality of the strain will be surprising. The plants have a tendency to revert after the removal of the heart comb to the comb form. These combs whenever exhibited should be removed, and this will throw more vigour into the feathery parts, causing fine-habited plants and a more dense and compact growth; in fact, judicious and early stopping (confining it, however, to the strong side shoots, and to the upper part so as to preserve the pyramidal form) is essential to freedom from comb, and to produce elegant feathery plants.

The culture required is exceedingly simple. From the middle of April to the middle of May is a suitable time to sow the seed, and from seed sown early in June I have seen plants surpassing in beauty and freshness for autumn decoration those sown at an earlier period of the year. The seeds require to be sown rather thinly in light moderately rich soil, and the seeds covered about an eighth of an inch deep. The pots should be placed in a hotbed having bottom heat of about 75°, and top heat of 65° to 75°, with a rise from sun heat and air. The seedlings require to have the soil moist, and yet if kept very wet they are liable to damp. It is important they be kept near the glass and be well ventilated, so as to induce sturdy growth. When the plants have two or three leaves in addition to the seed leaves they should be potted off singly in small pots, and not deeper than the first leaves, returning them to the hotbed and shading for a few days. The plants must be kept regularly moist, but still must not be overwatered. Shift the plants into larger pots as they fill with roots, potting rather firmly. The last shift may be into 9-inch pots, which are sufficiently large for the largest specimens, and at this move the drainage should be liberal, whilst for the others moderate drainage will suffice. The plants when grown too tall for a frame should be removed to a light house or pit, where they can be kept near the glass and have light on all sides. No artificial heat will be needed, providing the temperature, by moderate air-giving, be kept up so as to be that of a cool stove. The plants are the better of light sprinklings overhead morning and evening, and the floors and other surfaces kept moist. Liquid manure may be given at every alternate watering after the pots are filled with roots. Plants so grown will be tall and very effective for conservatory decoration. After they are fully developed they require to be carefully watered, or they will rot at the stem. If kept very dry the foliage becomes yellow, therefore water only to keep from flagging. The plants will remain in good condition for many weeks.

If dwarf plants are required we have only to keep them in small pots, standing upon boards or slates so that they do not root through into the hotbed, liquid manure to be given at every alternate watering and the plants kept near the glass. The soil in potting should be made very firm, and the shifts but two—*i.e.*, from 3-inch to 4½-inch, and from the latter to 6-inch pots, the sides of the balls at each potting being loosened so as to remove part of the close matting of the fibres. Shade for a few days after potting, as the plants from the loss of fibres would otherwise flag and the foliage suffer. The drainage at the last potting should be liberal, and in all cases it is better to use half-inch bones than crocks. Light turfy-loam three parts, and one part old cow dung or well-rotted manure, well mixed and broken up fine, will grow them perfectly.—G. Abbey.

WELLINGTONIA GIGANTEA.

We are enabled to publish two woodcuts, one of which gives a good idea of the size of this Brobdignagian tree, and the other of its cone which is but rarely seen.

The Wellingtonia was discovered by that young martyr of science, David Douglas, in 1826, and his journal of an excursion to obtain its cones is one of the most exciting of narratives. We have space only for one extract:—

"Thursday, October the 25th. Weather dull, cold, and cloudy. When my friends in England are made acquainted with my travels I fear they will think that I have told them nothing but my miseries. This may be very true; but I now know, as they may do also if they choose to come here on such an expedition, that the objects of which I am in quest cannot be obtained without labour, anxiety of mind, and no small risk of personal safety, of which latter statement my this day's adventures are an instance. I quitted my camp early in the morning to survey the neighbouring country, leaving my guide to take charge of the horses until my return in the evening, when I found that he had done as I wished, and in the interval dried some wet paper which I had desired him to put in order. About an hour's walk from my camp I met an Indian, who on perceiving me instantly strung his bow, placed on his left arm a sleeve of raccoon skin, and stood on the defensive. Being quite satisfied that his conduct was prompted by fear and not by hostile intentions, the poor fellow having probably never seen such a being as myself before, I laid my gun at my feet, on the ground, and waved my hand for him to come to me, which he did slowly and with great caution. I then made him place his bow and quiver of arrows beside my gun, and, striking a light, gave him a smoke out of my own pipe and a present of a few beads. With my pencil I made a rough sketch of the cone and Pine tree which I wanted to obtain, and drew his attention to it, when he instantly pointed with his hand to the hills fifteen or twenty miles distant towards the south, and when I expressed my intention of going thither cheerfully set about accompanying me. At mid-day I reached my long-wished-for Pines, and lost no time in examining them and endeavouring to collect specimens and seeds. New and strange things seldom fail to make strong impressions, and are, therefore, frequently overrated; so that lest I should never again see my friends in England to inform them verbally of this most beautiful and

immensely grand tree, I shall here state the dimensions of the largest I could find among several that had been blown down by the wind. At 3 feet from the ground its circumference is 57 feet 9 inches; at 134 feet, 17 feet 5 inches; the extreme length 245 feet. The trunks are uncommonly straight, and the bark remarkably smooth for such large timber, of a whitish or light-brown colour, and yielding a great quantity of bright amber gum. The tallest stems are generally unbranched for two-thirds of the height of the tree; the branches rather pendulous, with cones hanging from their points like sugar-loaves in a grocer's shop. These cones, are, however, only seen on the loftiest trees, and the putting myself in possession of three of these (all I could obtain), nearly brought my life to a close. As it was impossible either to climb the tree or hew it down, I endeavoured to knock off the cones by firing at them with ball, when the report of my gun brought eight Indians, all of them painted with red earth, armed with bows, arrows, bone-tipped spears, and flint-knives. They appeared anything but friendly. I endeavoured to explain to them what I wanted, and they seemed satisfied, and sat down to smoke, but presently I perceived one of them string his bow, and another sharpen his flint-knife with a pair of wooden pincers, and suspend it on the wrist of the right hand. Further testimony of their intentions was unnecessary. To save myself

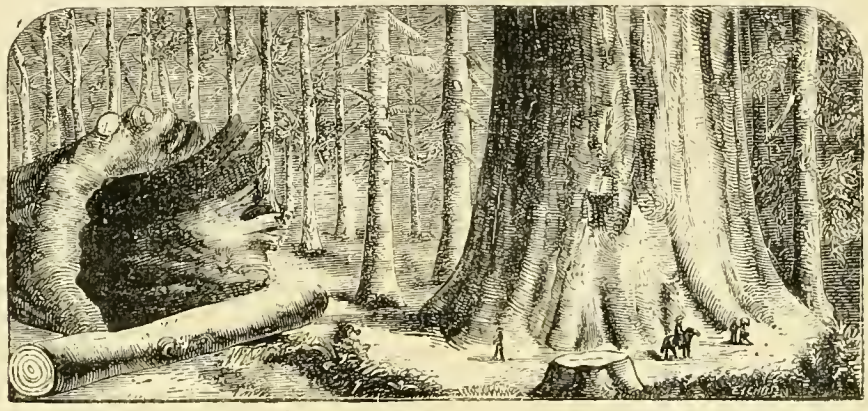

Fig. 94.—Bases of two of the trees.

by flight was impossible, so, without hesitation, I stepped back about five paces, cocked my gun, drew one of the pistols out of my belt, and holding it in my left hand and the gun in

Fig. 95.—Cone of Wellingtonia gigantea.

my right, showed myself determined to fight for my life. As much as possible I endeavoured to preserve my coolness, and thus we stood looking at one another without making any movement or uttering a word for perhaps ten minutes, when one at last, who seemed the leader, gave a sign that they wished for some tobacco: this I signified that they should have if they fetched me a quantity of cones. They went off immediately in search of them, and no sooner were they all out of sight than I picked up my three cones and some twigs of the trees, and made the quickest possible retreat, hurrying back to my camp, which I reached before dusk. The Indian who last undertook to be my guide to the trees I sent off before gaining my encampment lest he should betray me. How irksome is the darkness of night to one under my present circumstances! I cannot speak a word to my guide, nor have I a book to divert my thoughts, which are continually occupied with the dread lest the hostile Indians should trace me hither and make an attack; I now write lying on the grass with my gun cocked beside me, and penning these lines by the light of my Columbian candle—namely, an ignited piece of rosiny wood."

As a standard of comparison we remind our readers that the London Monument is 202 feet high, so that the Wellingtonias are higher than that by more than from 80 to 90 feet.

The following list of the synonymes and botanical description of the tree we copy from "Gordon's Pinetum"—"Wellingtonia gigantea, *Lindley*; Sequoia gigantea, *Endlicher*; S. Wellingtonia, *Seemann*; Washingtonia gigantea, *of the Americans*; W. Californica, *Winslow*; Americanus gigantens, *Hort. Amer.*; Taxodii, ap., *Douglas*; Taxodium Washingtonianum, *Winslow*. Leaves needle-shaped, spirally alternate, spreading, persistent, and of a light green colour on the young plants; those on the adult trees scale-formed, closely inlaid, rounded on the back and concave on the inner face; those on the branchlets much shorter, very close, and regularly imbricated; those on the larger branches longer, looser, decurrent at the base, and tapering to an acute point, but sometimes rather obtuse. Branches spread out horizontal, much divided, and furnished with numerous laterals. Branchlets cylindrical, frequently pendulous, and thickly covered with light-green glaucous foliage, cone-bearing ones slightly thickened and entirely covered with scale-formed leaves closely imbricated, the upper ones oval, and broadest at the base. Cones solitary on the ends of the branchlets, 2 inches long, and more than 1 inch in diameter, ovate, blunt-ended, and slightly tapering towards both extremities. Scales in series, placed nearly at right angles upon the axis of the cone, stipitate, thickened, and enlarged from the point of insertion as far as the summit, which is depressed and wrinkled on the external face, and furnished with a small prickle in the centre of the little hollow. Seeds from three to five under each scale, but mostly five. Seed leaves from three to six in number, but mostly in fours.

"According to Mr. G. L. Trask, who formerly exhibited a portion of the bark set up in the Crystal Palace to show the great size this tree attains in its native state, gives the following as the dimensions of one of the largest of eighty trees, growing in a grove at San Antonio—viz., height, 363 feet; circumference near the ground, 93 feet; circumference 100 feet from the ground, 45 feet; bark, 18 inches thick; age according to annual rings, from 3000 to 4000 years.

"It is found growing on the slopes of the Sierra Nevada, near the sources of the Stanislaus and San Antonio, in Upper California, in sheltered valleys, at an elevation of about 5000 feet. It is quite hardy and grows rapidly."

SETTING-UP GRAPES FOR EXHIBITION.

Grapes are very often seen inefficiently set up for exhibition, and are consequently not seen to the best advantage. This is especially the case at some of what may be termed country shows. I have therefore thought that fig. 96, taken from a photograph, would serve to show exactly what is generally considered by exhibitors of Grapes the best way of carrying and setting-up Grapes for competition. The bunch, it will be observed from the figure, is resting on a slanting board. The board is first covered with a thin sheet of cotton wadding, and then covered with a sheet of soft white paper. The bunch is cut with rather more than an inch of the Vine adhering to each side of its stem. A piece of narrow tape is fastened to the piece of Vine, and passed through a hole near the top of the back perpendicular board, and securely fastened there. To keep the bunch firmly in its place, a piece of narrow soft tape is worked with great care between the berries near the middle of the bunch with a long needle, and each end of the tape is passed through holes previously prepared on each side of the main stem of the bunch and tied underneath. The bunch is thus fixed so that it can neither slip down the slanting board nor roll about.

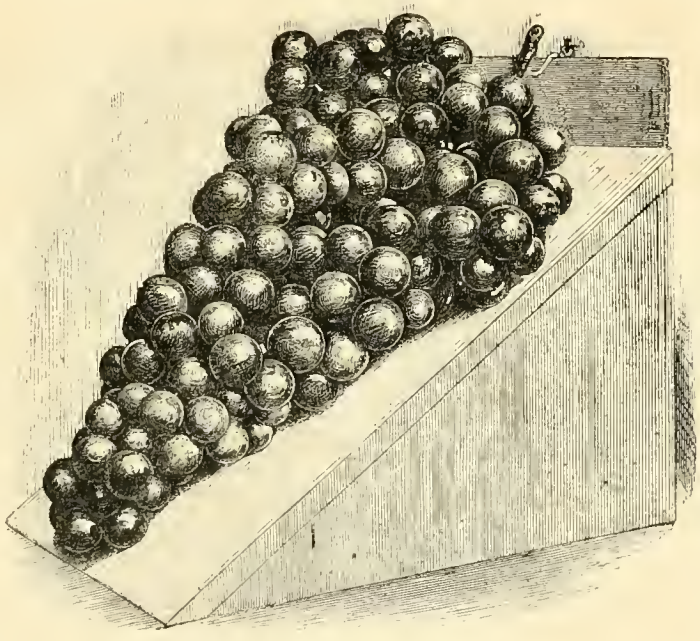

Fig. 96.

When more than one bunch is set up, the Grape-board must be of proportionate length. But it is not desirable to have them longer at any time than will hold three to four bunches, with sufficient space between each to let them be properly inspected.

It is always best to fix the bunches just as they are cut from the Vines, always laying them on their flattest side. In doing this it is never desirable to lift a bunch after it is laid on the board, for it cannot be easily done without more or less disturbing the bloom of the Grape. When all are fixed in their places, fit what I shall call the exhibition platform into a square box just wide enough to take it in, and deep enough to clear the fruit when the lid is screwed on; then put a couple of screws through the box from the outside into the back board of the platform, and they cannot move. In conveying them care must be taken to keep the box level, and not to jolt it severely.

PACKING GRAPES.

The packing of Grapes to be sent long distances by rail and other conveyances requires to be carefully managed. There are many ways of packing them. I have seen each bunch laid on a thick stiff sheet of paper, and folded up sufficiently tight to prevent the bunch from moving about in the paper. They are then packed closely in boxes sufficiently deep to admit a layer of paper shavings under and over them, so that when the lid of the box is fastened down each parcel was held securely in its place. The stiffness of the paper is supposed to come in contact with the bunch at fewer points than when wrapped up in more flexible paper, and on that account to better preserve the bloom. There is, however, at the same time room left for the oscillation of those berries not in immediate contact with the paper, and this is objectionable. In sending Grapes to a distance I have never adopted this mode of packing, but have either wrapped each bunch in a sheet of fine tissue paper, and packed them on a firm bed of paper shavings as close as they would lie, with just sufficient wadding between each to fill up the irregularities of the outline of the bunches. When the box is thus filled a sheet of wadding is spread regularly over the bunches, and over all a layer of paper shavings, so that when the lid is shut down they are subject to as much pressure as prevents their moving. At other times, when only sending a few bunches in one compartment of a box, I have spread a sheet of paper over the shavings in the bottom of the box, and laid all the bunches as nicely fitted into each other as possible on it, then put another sheet of tissue paper over them, then some cotton wadding, finishing off with a layer of paper shavings. In this way I have always found them go quite safely. When a quantity has to be sent in one box it should be divided into compartments, so that when the box happens to be set down standing on end or side, the Grapes at the lower part of it cannot possibly be subject to much pressure from the top end of the box. I do not know of any way of sending them to preserve their bloom, for unless some person is sent with the box there must be packing material on the upper side of the Grapes.

Those who grow Grapes extensively for the fruit market, and have to send them in large quantities by rail, pack differently from any of the methods described above. Indeed, they use next to no packing material whatever. They place a few flexible paper-shavings in the bottom of a nearly oval-shaped wicker basket with sloping sides. The Grapes are cut and laid in layers round the sloping side of the basket, and layer after layer of Grapes are laid on without any packing material, until the basket is finished with a bunch in the centre. In this way they are packed firmly to prevent oscillation, and it is astonishing how little the bloom is tarnished. The baskets are then put into wooden boxes, generally two storey deep, and sent by passenger train. The fruiterer or salesman meets them at the terminus. Tons of Grapes are thus sent hundreds of miles to market with the greatest safety. The only danger of damage is from the upsetting of the boxes or any severe concussion.—D. Thomson (in *The Gardener*).

NOTES AND GLEANINGS.

It has been arranged to hold an International Fruit and Flower Show at the Alexandra Palace on the 2nd, 3rd, and 4th of September next. A liberal schedule of prizes will be issued in a few days.

—— We are sorry to learn that the Keighley Agricultural Association's Show has to be abandoned this year in consequence of the prevalence of small pox in the town and neighbourhood.

—— The Croydon Meeting of the Bath and West of England Society, commencing on Monday, May 31st, and extending over the four following days, promises in all respects to surpass any of its predecessors. The showyard, thirty-six acres in extent, is situated at Waddon, about half a mile distant from the Croydon railway station; and the entries in all departments are large and important beyond all precedent. The Poultry Show will be the largest ever held by the Society, and remarkable for the numerous entries of birds best adapted

for farm purposes. Altogether there are not less than 550 pens, 100 of which are Pigeons. The horticultural tent, under the direction of the Hon. and Rev. J. T. Boscawen, will contain a rich display of plants and flowers, contributed by eminent growers in the neighbouring counties. For the convenience of visitors special railway arrangements have been made by the several railway companies.

—— Our readers will regret, as we do, that our columns will contain no more of the notes from New Zealand contributed by Mr. William Swale. He died at Avonside, Christchurch, in that island, on the 18th of February.

—— Messrs. Barr have sent us a very pleasing posey of varieties of the Wild Hyacinth. There are three or four shades of blue and pink, and two forms of white. Some are single and others double. They are, of course, all hardy border flowers.

—— The splendid collection of Vandas of Mr. Robert Warner, at Broomfield near Chelmsford, is now in full bloom. Those who have had the pleasure to see Mr. Warner's collection know how rich it is; and as Mr. Warner is courteous enough to allow visitors to view his Orchid houses, now is a favourable opportunity for doing so.

—— Vine-culture in New South Wales is progressing very rapidly, the number of acres occupied for this purpose being 3183 in 1873, against 2568 acres in 1872, and the produce 575,985 gallons against 451,450 gallons. These figures relate only to the growth of Grapes for wine-producing purposes, but a considerable area is devoted to the cultivation of the Vine for other objects. In Western Australia also, where the soil and climate are eminently favourable to the growth of the Grape, this pursuit is becoming more general.—(*Nature.*)

NOTES on VILLA and SUBURBAN GARDENING.

Disbudding and Thinning Fruit.—There is a remarkable growth on most fruit trees this spring, and they advance so rapidly that no time must be lost in attending to them. Where the wood of Peaches, Nectarines, and Apricots has been laid-in rather thickly, and every bud almost has produced a shoot, thinning must be attended to forthwith. The work should be commenced at the thickest part of the tree first, otherwise the under leaves and fruit become yellow from the want of air and soon drop off. This is one reason why the buds at the base of a shoot are so often undeveloped, resulting in a naked part some 6 inches up the shoot when the tree breaks into growth another season.

As a rule disbudding should be begun early, as it is a work requiring the greatest care and judgment, and if it is done properly there will be less necessity for winter pruning. The object should be to secure an equal balance of strength in all parts of the tree, and every shoot left should have a place assigned it. The body of the tree should be especially considered, because the trees after attaining a good size are frequently naked at the base and centre, which always shows signs of bad management. I know of no particular rule as to the distance shoots should be left, for it may be that two of them must be left pretty close together in order to take the places of two to be taken out at the winter pruning, or, taking the reverse of that, it may be necessary to go a considerable distance, say 8 or 10 inches, on account of good young bearing wood of promise being close at hand. It must be understood that I am alluding to side shoots, as it is not frequently the case to interfere with the leading shoot, though sometimes that not being healthy it would be well to take it out and trust to a more promising one a few inches back; but there is generally a little sacrifice of fruit by this plan, because no fruit comes to perfection in advance of the leading shoot, unless it is allowed to grow a little foliage with it. This suggests that in disbudding, those shoots that are not wanted, and yet have fruit at their base, ought not to be taken clear out, but pinched off two or three joints beyond the fruit, which ensures the flow of sap and proper development and flavour of the fruit.

With regard to Apples, Pears, Plums, &c., that produce their fruit from spurs, not much disbudding is necessary, but rather a system of pinching-back to three or four joints, and this ought not to be done till the shoots are advanced so far as to make sure they are not fruit buds. These only grow a certain distance, and then begin to form a knot or bud, and show no sign of further elongating. After disbudding it is astonishing what rapid progress in growth the shoots make, therefore, as soon as possible, fasten them to the wall. Possibly, if not delayed too long, one nail to a shoot would be sufficient. By no means should shoots when growing fast be nailed too close to the point, for this in many cases cripples them. The chief object is to secure them against injury from wind.

Thinning the Fruit.—This operation is especially necessary this year. Like disbudding, it should be done at several different times, first taking out those that are most crowded and those which are ill-formed or misplaced. A sharp-pointed pair of scissors is a handy instrument for the work, as pulling the fruit off, especially if they are healthy and firm on the tree, runs the risk of pulling a strip of bark off as well, and then comes a risk of gumming or canker, because at such places the wound does not repair itself before winter sets in, and at such tender places the frost suddenly takes effect, because after all the Peach and Nectarine are not really hardy fruit trees.

As to the distance at which the fruit should be left I know of no strict rule; this must be left to the operator, who ought to be the best judge of the state of the tree, whether in good health, or bad, or medium. On a vigorous tree the fruit may be left thicker than on one less robust, and in some parts of the tree it may be allowed to carry more fruit than another. The soil must also be taken into account. In good soil a tree may be allowed a heavier crop than if the reverse, or even an approach to it, is the case. The plan which I practise myself is to take a general survey of the tree, and take all the above points into consideration, and judge accordingly.

I believe there are no fruits grown but what would be much improved in size and flavour by a judicious system of thinning, even down to the humble yet useful Gooseberry and Currant.—Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

It is many years since we had such a good show for fruit on walls, standard, pyramid, and dwarf trees. Plums have set well, notwithstanding that the blossoms were exposed to frost winds from the east; the trees are also free from insect pests. Last year the trees suffered much from swarms of aphides, and though we failed to rid the trees from the insects until the young wood had suffered severely, the injury is not apparent this year. The best way to destroy the aphis is to syringe with water in which soft soap has been dissolved, and if a little tobacco liquor is mixed with it so much more effectual will be the application. We have done nothing to the trees as yet except to keep the hoe at work amongst them. It is too early to stop the young growths. Strawberry plants are growing very strongly, but if the present hot and dry weather continue it will be desirable to give them a good watering.

Wall fruit requires attention now. Apricots should have a final thinning, as the fruit is approaching the stoning period. Growths not required should be pinched back to two or three leaves. Peaches and Nectarines on walls must now be attended to. As all the fruit is produced from the young wood and seldom from spurs all the foreright growths should be rubbed off, and only a sufficient number of shoots left on to produce the bearing wood for next year. Watch for aphis, and on the first appearance of it syringe the trees.

Passing through one of the largest gardens in the country some time ago a remark was made about the very unhealthy and weakly condition of the wall trees, and the gardener stated that they were very nearly lost from an attack of aphis. When the young wood and even old branches persist in dying-off during the winter months, and the trees are otherwise in an unsatisfactory condition, the chances are that the reason is to be found in imperfectly-ripened wood from the attacks of red spider or other insects. If the trees are encouraged to make healthy growth in summer, and the wood has ample space allowed to develope itself and to ripen, we should hear of fewer complaints of shoots dying-off "without any apparent cause." If a tree produces gross watery growths in summer then the roots are wrong, but if solid fruitful wood is produced this will not suffer in winter. If time cannot be spared to properly attend to the Peach wall, it will be better to root-out the trees and plant Apricots and the finer Pears. Young trees that have not yet covered the wall must be seen to, or leading growths may be broken off by gales of wind. Nail-in all the wood that will be required, and stop back growths that are not wanted. A hint may also be required about trees that were grafted in March or April or budded last autumn. The clay may be removed and the bandages loosened, removing all shoots that start from the stock; the young growths should be supported with sticks, and be tied to them as they advance.

FRUIT HOUSES.

Vineries.—In the earliest houses the Grapes are very nearly ripe, and after this time the only care requisite is to keep the berries plump and free from dust. No plants should be allowed in the house, and it will seldom be necessary to sweep the paths, but if they require to be done a little water sprinkled first will prevent the dust from rising. Sometimes lateral growths will ramble out of the bounds allotted to them at this time, and if they are cut back now they will not start again. The Grapes should be well shaded by the leaves if it is intended that they should hang long. There is plenty of work in the late houses,

setting the fruit, stopping lateral growths, and training them down to the wires.

ORCHARD HOUSE.

The trees have all been re-arranged and more space allowed by removing some of the Pear and Plum trees outside. The growths have also been stopped and thinned out; the house is also syringed night and morning, applying the water with considerable force from a garden engine. Strawberries on the shelves are either in flower or the blossoms have set; in the latter case the fruit has been thinned out to from six to a dozen on each plant. The fruit must also be supported above the leaves with sprays of Elm or Beech. When the fruit is set apply the syringe vigorously to the under sides of the leaves, it is the only certain way to keep the plants free from spider. Our plants are now freely watered, and every alternate watering is with liquid manure.

CUCUMBERS AND MELONS.

The work in this department is comparatively easy, as but little artificial heat is required. Thinning-out the old growths and tying-in others in their place must be attended to. There is no excuse for spider being on the leaves, as the syringe may be used two or three times a-day. Cucumber houses may be used for other purposes if required during the summer months, as a plentiful supply of fruit may be obtained from frames. With good management Melons that were sown in January will now be producing ripe fruit; this should be supported to the trellis on small boards fixed under the plant and attached to the trellis by wires until it is quite ripe. It can easily be known when the fruit is ripe by the perfume which it gives off, and by cracking round the stem where it is attached to the fruit. If the fruit is not required at the time it is cut from the plant it may be removed to a cool room, where it will keep a week or ten days.

GREENHOUSE AND CONSERVATORY.

Air should now be freely admitted, the ventilators front and back should be thrown open to their fullest extent unless the wind is high. They may also be left open all night unless tender plants have been brought in from the stove or forcing houses. Water must also be applied freely to the plants: of course it may be overdone, but a little care would prevent this. All plants making their growth must be watered before the mould in the pots becomes so dry as it is allowed to do when plants are at rest or in winter. The hair-like fibres of Indian Azaleas, Cape Heaths, and many New Holland plants are seriously injured if the soil becomes so dry that the ball shrinks away from the sides of the pot. Another evil of equal magnitude is imperfect drainage. When the plants are repotted the crocks should be laid in carefully, and an inch of fibry peat free from dust should be placed over them. If worms are excluded the compost will be effectually prevented from mixing with the drainage. If the drainage is choked or the plants suffer at any time for want of water, it will not be possible to grow them into handsome specimens, and some of the more choice and miffy plants, such as Hedaroma tulipifera, and nearly all the Heaths are liable to die off through the ill-treatment. Epacris and the early-flowering Heaths will be repotted if possible this week, using only rough fibrous peat; if naturally sandy all the better, as bog peat is not adapted for Heaths and Epacris.

Cinerarias have bloomed well up till now, but as they were looking seedy the plants were placed in a cool shady place, where they will furnish cut flowers for a week or two. Stage Pelargoniums well advanced towards the flowering period have taken their place. In case any green fly should be upon the plants, as a precaution the house has been fumigated. If this is delayed until the flowers open the smoke will cause the petals to drop off.

The never-failing perpetual-flowering Carnations make a grand show, the fiery Proserpine, the flesh-coloured Miss Jolliffe, the Picotee-edged Picturata, and the pure white Avalanche, with many other intervening shades and stripes, give us a profusion of most useful flowers. Cyclamens have been stripped of their flowers and seed pods, and with the Primula amœna have been removed to a cold frame, where they are shaded from the noonday sun.

Roses in pots—Teas and Hybrid Perpetuals—claim considerable attention. In the house, where no artificial heat has been applied, the Teas are just opening their flower buds. Niphetos, with its white shell-like petals, is very beautiful; it is a fine Rose, and but few of the new sorts come up to it. Belle Lyonnaise is a fine hardy Tea Rose; it opens well in the house. Madame Margottin is superb indoors, but opens badly on a wall outside; Madame Falcot and Safrano are best in the bud; Niphetos is also a fine button-hole flower. Mildew and the bud worm have been very troublesome to us; the one has been destroyed by hand-picking, and the mildew by dusting with flowers of sulphur.

FLOWER GARDEN.

Bedding-out was begun on the 12th, although it has been a dry season; the beds not occupied with spring-flowering plants are sufficiently moist, and the weather is in our favour; we plant deeply, and thoroughly water the plants before putting them out. It is almost a pity to disturb the beds of spring-flowering plants; the season so far has been late, and Wallflowers, Myosotis, Silenes, and some other favourites are in full beauty. Placed sticks to Carnations and Picotees; stirred the mould in the pots, and picked off withered leaves. Pinks in beds have received similar attention, and the beds have been watered.—J. Douglas.

TRADE CATALOGUES RECEIVED.

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogues of Herbaceous and Alpine Plants, and Stove and Greenhouse and Bedding Plants.*

Francis & Arthur Dickson & Sons, The Upton Nurseries, Chester.—*Catalogue of Florists' Flowers and Bedding Plants.*

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

CRYSTAL PALACE COMPANY.—Flower Show, May 29th; Rose Show, June 26th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.

COVENTRY.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.

LEEDS.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.

BURTON-UPON-TRENT.—June 16th. Mr. Wm. Shave, Bond Street, Sec.

JERSEY.—Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

GLASGOW.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.

EXETER (Rose Show).—June 18th. Mr. J. N. Gray, Queen Street Chambers, Hon. Sec.

FAREHAM.—June 23rd. Mr. H Smith, Sec.

STOWMARKET.—June 24th and 25th. Mr. S. Prentice, Hon. Sec.

REIGATE (Rose).—June 26th, 1875. Bushby Britten, Esq., Hon. Sec.

WISBEACH.—June 30th. Mr. C. Parker, Hon. Sec.

MAIDSTONE.—(Roses), June 30th, at Vinters Park. H. Beanstead, Esq., Hon Sec., Rose Club, Mill Street, Maidstone.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*A. C. K.*).—The "Vine Manual." You can have it free by post if you enclose thirty-two postage stamps with your address.

GRAPES SPOTTED (*H. H.*).—The specks on the stalks are natural, but the spots on the berries are disease. The roots are torpid; water them freely with weak tepid manure water, and put fermenting dung over the surface above the roots.

AURICULA SEEDLINGS (*Manor*).—You are too impatient. You must not expect your Auriculas from seed sown last year to bloom until next year; some, perhaps, not then.

ROSE SEEDS (*G. W. J.*).—Rose seeds will often, if not generally, produce a great proportion of single or semi-double flowers, but the foliage would certainly be different from that of the Dog Rose or Briar, and we certainly should be disposed to think that if your Rose seed sown produced nothing but Briars that the seeds must have been saved from the hips of the Dog Rose; but if by Briars you mean single wildings, they may be the produce of Rose seeds much degenerated.

ANNUALS RABBITPROOF.—"*L. G. S.*" wishes to know of some hardy flowers and annuals that rabbits will not eat. We stated last week all the shrubs they leave unnibbled.

NAME OF ROSE (*R. Maitland*).—It is difficult to say from the specimen enclosed, but possibly it is Thoresbyana, a strong-growing nearly-evergreen climber raised at Thoresby.

FLAT PEACH OF CHINA (*J. F.*).—We are not aware of this Peach being in the hands of any of the nurserymen. If you are particularly desirous of procuring it you will find it in the nursery of Messrs. Simon-Louis of Metz; or you might try Mr. Van Houtte of Ghent.

MARÉCHAL NIEL ROSE (*G. G.*).—The Rose branches or shoots may be introduced into the greenhouse, the plant being in a border outside; but it will be necessary to wrap the stem in winter by a hayband, or adopt other means of protection from frost. Tea-scented Roses do not require close pruning, but only to have the weak parts thinned, and any long shoots shortened-back so as to remove unripe wood. The less pruning they have the more are they likely to flower.

APHIS ON PEACH TREES (*T. S.*).—Syringing is not the best means of clearance, nor is it at all times safe to apply a destroying agent in a liquid form; but fumigation with tobacco is at all times a safe and efficient destroyer of these pests. If one fumigation be not effectual repeat in a day or two, and whenever the insects are seen. If the trees are outdoors the best

remedy is to syringe with tobacco juice diluted with six times its volume of water, containing 2 ozs. of soft soap per gallon. It will not injure the young fruit, but we should not advise it being applied to trees in blossom.

MEN REQUIRED FOR A GARDEN (*Constant Reader*).—For the kitchen and fruit gardens two men will be required, one for the lawn and flower garden, one for the drives and shrubberies, and a journeyman gardener and apprentice or youth of sixteen to eighteen for the houses, with a youth or two or women for leaf-clearing, &c. We have made an allowance of a man for the extra labour and odd jobs, and with these named we think the place you describe could be well kept. The calculation does not include the head gardener, who can always be profitably employed in the higher branches of the art without participating in heavy labour.

TULIPS AFTER BEING BEDDED-OUT (*A. P. S.*).—They do not improve from being grown in this country, but rather deteriorate, from the practice of taking them up before the growth is complete to make way for the summer occupants of the beds. Left in the soil until the growth is complete they are little inferior to imported bulbs. The address we think you want is Messrs. J. Dobson & Son, Isleworth and Hounslow, London, W.

CABBAGES CLUBBING (*Henry Tulk*).—The disease you allude to is the club or anbury, which is caused by a weevil, or rather its larvæ. The plants should be examined at planting, and upon their stems will be found, in many instances, a knob or excrescence, which contains a small white maggot; this being removed the plant may be planted without sustaining any injury. To keep the grub at bay apply a dressing of gas lime to the ground before planting, and point-in with a fork, applying it at the rate of ten bushels per acre. Salt is also a good application, and so is soot, either at the rate of twenty bushels per acre, but the gas lime is the most effectual.

SYRINGING FRUITING STRAWBERRIES (*J. B.*).—They should not be syringed overhead when in flower, and only very lightly after they are set and are swelling, discontinuing it after the fruit commences to ripen; the fruit then to be kept dry, as water resting upon it causes it to spot and decay. Water abundantly at the roots with weak liquid manure.

CLIMBERS FOR WIRE ARCHES (*Idem*).—Clematis montana major, Caprifolium sempervirens floribundum, and Jasminum nudiflorum. Roses of the climbing class are very suitable, as Dundee Rambler (Ayrshire), Princess Louise Victoria (hybrid climbing), and Russelliana (multiflora).

PLANTS FOR A GRAVE (*Eve*).—Few plants are suitable for a grave to remain permanently, as, when not in flower, they have a neglected appearance. It is much better to have changes, though some, as Snowdrops, the blue Squill (Scilla siberica), Primroses—the common and the double forme—the spring and summer Snowflake (Leucojum vernum and L. æstivum respectively) may be allowed to remain permanently; also, Lily of the Valley and Violets, blue and white, double and single, a plant or two of Christmas Rose (Helleborus niger) and Cyclamen neapolitanum, which flowers in autumn before the leaves, the leaves coming up after, and are very pretty. Most of these will flower in the early part of the year, and you may add Forget-me-nots; nice plants with balls planted in spring will flower finely in April and May, and in summer we should have an edging of Silver-variegated Ivy-leaved Geranium, and fill-in the centre with compact dwarf plants of Fuchsias, both light and dark varieties, planting them in the spaces between the permanent plants. They would come off in the autumn, and we should then introduce in the spaces nice little plants of Andromeda floribunda, Skimmia japonica, and Erica herbacea carnea on the margin, with Thujopsis dolabrata, and Cryptomeria elegans in the centre. These will give an interesting appearance in winter, and need not be removed until the summer plants are put in. The subject is so difficult that we should be obliged by information.

PRUNING NEWLY-PLANTED TREES (*T. E. S. B.*).—They, if having long shoots, should have been pruned, but if they had been closely summer-pinched they would not require it. If they have long shoots and have not been pruned—*i.e.*, the shoots shortened, they will be in the plight you describe. On the general question of pruning you are right.

ANTS AND GREEN FLIES (*D. W. W.*).—The ants are said to attack the aphides, but we incline to think they feed upon the sap which the insects cause the leaves to exude. The Pear-tree leaves in your envelope represent the roots of the tree to be inactive. Fresh soil and rich top-dressings we should recommend as a proper remedy.

ASPHALT DRIVE (*L. M.*).—The drive should have a proper foundation of clinkers, brickbats, or rough gravel, and these should be broken up, and a regular inclining yet even surface given before putting on the asphalt. The following receipt is from the "Cottage Gardener's Dictionary:"—"Take two parts of very dry lime rubbish, and one part coal ashes, also very dry, and both sifted fine. In a dry place on a dry day mix them, and leave a hole in the middle of the heap as bricklayers do when making mortar. Into this pour boiling-hot coal tar, mix, and when as stiff as mortar put it down 3 inches thick to form the walk. The ground should be dry, and be beaten smooth. Sprinkle over it coarse sand. When cold pass a light roller over it, and in a few days the walk will be solid and waterproof." A neater appearance is given by sprinkling with spar, yellow or other gravel, which must, of course, be fine, and put on immediately after laying down the asphalt in place of the sand It will bear horses without breaking-up.

CUCUMBERS NOT THRIVING (*H.*).—The atmosphere is probably too dry, and cold air currents have an injurious tendency on the leaves and swelling of the fruit. The ventilation being on the north side only, and having had a prevalence of easterly and northerly winds, we do not wonder at the plants being in the plight you describe. Probably some woollen netting over the opening would mitigate the evil.

MELONS SWELLING IRREGULARLY (*F. H.*).—The fruit not swelling is, we think, the result of imperfect impregnation. There is no remedy but to have a healthy root-action prompted by brisk bottom heat, and to have rather more than twice the number of blooms impregnated upon a plant in one day, and of those you will generally find a sufficient number to swell kindly. When you have three or four upon a plant swelling freely the others may be removed The ligatures you suggest would be ineffectual.

YOUNG POTATOES AT CHRISTMAS (*P. M.*).—There are two, and probably more, ways of having young Potatoes at Christmas. Both cases are met by saving tubers of the preceding year's growth, but treating them in a different manner. The moderately-early Kidneys are best. By the one plan they should be laid thinly in a cool and dry place, the sprouts not removed, and at the middle of July they should be planted in an open situation in rich light soil, and in October they will have formed good-sized tubers, which should be taken up, stored in boxes in dry soil and made firm, keeping in a cool place until wanted, but safe from frost. Others treated as regards the sets in a similar manner may be planted in rows 2 feet apart in a warm and dry border early in August, and these are to be left in the ground until wanted, they being protected in severe weather with leaves and litter. These are infinitely superior than these produced by the following plan. Sets of the preceding year are kept in any cool and dry place, the sprouts are removed as they appear, and at the close of July or early in August they are placed in boxes in light rich soil, with 6 inches of soil over them, or in layers with that amount of soil for each. They should be kept in a cellar, or any place having a temperature of 50° to 60°. In about three months they will have formed tubers without top growth, and of such there is only one conclusion—they are insipid, and not comparable to those grown by the other methods, or to those forced in frames.

PLANTS FOR ROCKERY (*W. Russell*).—Your rockwork will be suitable for the following plants. After they become established they will not require artificial watering, except in an exceptionally dry period. Acæna novæ-zælandiæ, Achillea umbellata, Alyssum saxatile compactum, Arabis albida, Aubrietia deltoidea, Campanula garganica, Cheiranthus alpinus, C. Marshalli, Cistus algarvensis, Cyclamen coum and var. vernum, Dianthus floribundus, Draba aizoides, Ericas in variety, Erysimum pumilum (similar if not synonymous with Cheiranthus alpinus), Gentiana verna, Iberis gibraltarica, Linaria alpina, Linum alpinum, Lychnis viscaria splendens, Orobus vernus, Oxytropis pyrenaica, Petrocallis pyrenaica, Santolina a pina, Saponaria cæspitosa, Saxifraga affinis, S. cæspitosa, S. coriophylla, S. juniperina, S. oppositifolia, S. palmata, S. umbrosa elegantissima, Sedum acre and var. anreum, S. anglicum, S. Ewersi, S. Forsterianum, S. Kamtschaticum, S. pallidum roseum, S. sempervivoides, Sempervivum arachneidenm, S. californicum, Silene acaulis, S. pumilio, Veronica prostrata.

SHADING GLASS (*Idem*).—There is nothing better than a wash formed of whiting and skim or buttermilk to the consistency of whitewash and applied with a brush to the inside of the house roof. It is easily cleaned off when shading is not required.

BEETLE ON ROSES (*W. L. P.*).—The specimens you enclosed were a common weevil, Curculio sulcatus. The best mode of destroying them would be to spread a sheet beneath the bush after dark and shake it. The insects are then feeding and would fall on the sheet.

NAMES OF FRUITS (*J. Mollet*).—Your Apple is Bess Pool.

NAMES OF PLANTS (*Rev. S. A. Brenan*).—Polemonium cæruleum and its white variety. (*W. F. R.*).—An Echeveria, perhaps E. secunda. (*J. S.*).—Bougainvillea spectabilis. (*Thos. Perry*).—1, Pulmonaria officinalis; 2, Omphalodes verna; 3, Euphorbia amygdaloides; 4, Myosotis sylvatica (*Inquirer*).—Apparently Prunus virginiana. (*C. W. M.*).—The Wych Elm (Ulmus montana). (*A. B.*).—Rosa Banksiæ. (*B.*).—Specimens quite insufficient. "Grains of Paradise" are the seeds of Amomum Meleguetta. (*C. B. H.*).—1, Melalenca sp.; 2, Lantana sp.; 3, A better specimen would oblige. (*P. W.*).—Gongora atropurpurea, *Hook.* (*Bot. Mag.* t. 3220).

POULTRY, BEE, AND PIGEON CHRONICLE.

COTTAGERS' SHOWS.

SURELY the price of chickens for table use has reached its acme. The other day at a fashionable watering-place we were asked 10*s.* 6*d.* a couple for spring chickens. When we hear of these prices we can only think the demand must enormously exceed the supply. Of course 10*s.* 6*d.* was a fashionable price, the ordinary market charge being about 8*s.* or 8*s.* 6*d.* a couple; but even supposing the price was 7*s.* 6*d.*, what a help a brood or two of early birds would be to a cottager!

This year chickens have been very scarce; but in most years the cottagers and small farmers in Sussex are able to rear early broods, which help to supply our London markets to a great extent. The higglers go round to the villages, and buying up the birds take them home to fatten; but even the Sussex cottagers know that chickens are valuable, consequently the higglers have to pay pretty well for the early spring birds.

Sussex is not the only county where there are country lanes and open common land. Chickens can be as well produced in Hampshire, Kent, Surrey, and other counties as Sussex, and we wonder more is not done towards encouraging our cottagers to add by this simple method a few shillings to their weekly receipts. We are sure many can easily keep four or five hens, and have a good profit from them, their cost of keep in a country home would be so trivial, that the greater part of the receipts would come on the profit side. There are some who think that cottagers can cultivate poultry for their own use as an economical and cheap food in these days of dear mutton and beef; but this we do not believe, for if once a cottager tried to do this he must keep a large number, and this would in most cases end in ruin. We have so often been shown that where five hens can be kept profitably ten will not pay; but we do believe that while chickens realise the good prices they do it will always be very profitable for our cottagers to keep a few birds. The early eggs and early chickens will find a speedy sale, and be the means of procuring many a little comfort which otherwise could not be afforded out of the weekly wages. We believe everywhere fowls are becoming more numerously kept by the labouring classes. In the north we know they are, and we hope so, too, in the south. We think if those who have the power of doing so will only help the cottagers to see what an advantage poultry would be they would be helping in a good work. We are sure village shows afford a capital way for exciting the love of poultry about the cottage homes. We know of a few villages in one corner of Sussex which club together and have a regular annual gala day. It is often impossible for one village to manage a show, but three or four can work together, and select for their committee members from each, and then hold

the shows in the different villages by turn. We are convinced such shows are appreciated, and help on the cultivation of poultry among the poorer classes. We would not restrict such exhibitions to poultry only; far from it, we would make them embrace everything that is interesting to a country life, and give prizes for fruit and flowers, best-kept gardens, window flowers, honey, bread, butter, needlework, and everything in which members of a cottage home can take part. It is in the southern counties especially where such village shows would do good. The men are principally labourers, earning but just wages enough for bread and butter. In the north the manufacturing districts hold out such a pleasant tariff of wages that the poultry fanciers there are able to compete, and do so successfully, at the many local shows for which Lancashire and Yorkshire especially are so famed. We hope some of the leading people in villages and country parishes will take up the matter more, and see if they cannot help on some such shows. Perhaps a few particulars of the little show held in the corner of Sussex, to which we before alluded, may be of service.

The district for competition is open to eight villages. Anyone from those parishes may compete, and to encourage the cottagers to exhibit as much as possible, no entrance fees of any kind are charged. We believe when this little Society first started, some kind and influential tradesman offered his services as Hon. Sec., and to him its success is to a great extent attributable. Consequently, in forming new societies we would especially advise an able business-like man being chosen if he can be found to fill this post. Then a Committee was formed of two or three tradesmen out of each village, who appointed the most central place for their committee meetings, and so started their Society. Of course they could not do much without money aid, but every one was glad to subscribe his or her mite to such a good purpose, and the Committee, members of each village, collected from their own gentlemen, tradesmen, farmers, and cottagers. Subscriptions and donations were given as small as 6*d.*, and very few exceeded 10*s.* even from the wealthiest landed proprietors; consequently no influential squire is absolutely necessary to set this sort of show going. The inhabitants of one village are as well able to do it as those of another.

We find from last year's balance sheet the eight villages of this Society made up in donations and subscriptions £93 10*s.* 6*d.* The largest sum collected from one village was £20 0*s.* 6*d.*, and the least £2 11*s.* 6*d.* The greater part of this sum was expended in prizes—viz., £85 15*s.* 6*d.* They were not of themselves valuable premiums, but were many in number; a cottage loaf, a patchwork quilt, a lettuce, and a Dorking cock had all chances of winning the same sum of money. These good people make it a regular gala day; most of the farmers give their men a half-holiday, and all have to pay 6*d.* to go into the showyard from 1 to 4 P.M., and after then 3*d.* The amount taken at the gates in these small sums came to £54 18*s.*

It is important to have such a show held in a suitable place. Most villages, however, have some squire's park, and if permission can be obtained for the show to be held in them the pleasure is even much greater for the visitors than if it was held in a field. The gentlemen who kindly give the use of their grounds for the meetings of the Society about which we have been writing also throw their gardens and private walks open, so the day is really looked forward to by all the villagers as *the* day of the year.

There are, of course, expenses, such as hiring pens and band, labour, printing, postage, &c.; but these should be covered by the gate money, while the money collected in subscriptions is spent in the prizes. The report and balance sheet this Society have just issued is their sixth, and by it we see they have a balance in hand of £28. There are such things as wet days even in August, so it is well to have a reserve fund.

As far as the results of the poultry department of this Exhibition go, with which we are here most nearly concerned, we know from experience that it has worked much good. Not only do the cottagers in very many instances now keep a few birds who never before had a feather, but they keep a better class of birds and of more profitable breeds—Brahma-Dorkings and Houdans for spring chickens, and Hamburghs for laying. We know of many cottagers who have gone in for their few chickens and made a good thing of them; and what one can do all can. We do not advocate the subdivision of classes for such shows, but there should be classes for Dorkings, Brahmas, Cochins, two kinds of Hamburghs, French, and Ducks. These could be more subdivided, but those classes which we have named we consider essential, and we believe when the operations and working of such associations are better understood there will be annually a still further increase in the number of exhibitors. We do hope that some kind patrons will come forward and try to start such village exhibitions in places where they do not already exist, for we are convinced that by stimulating the energies of the cottagers in this way great good will ensue.—W.

Early Swarming.—I have seven stocks of bees from which I have two large natural swarms, one on the 1st of May, the other on the 8th.—Thos. Corney, *The Gardens, Eden Park, Claines, Co. Limerick.*——On Friday last, May 14th, a friend of mine at Ashton-on-Mersey, six miles south-west of Manchester, had a swarm of bees. To-day, May 17th, I also had a swarm. I am six miles south-east of Manchester. Both swarms English or black bees.

CHICKENS FROM EGGS ONE THOUSAND AND TWO HUNDRED YEARS OLD.

The Paris correspondent of *The Nation* states that the guests of the Abbé Denis, curate of the parish of St. Elio, in the Faubourg St. Antoine, dined a few days ago on fowls whose immediate ancestors figured, he says, on the table of the great Frankish King Dagobert. When the Abbé Denis laid the first stone of the church and presbytery he has built by his own exertions on the site of the old château and gardens of Dagobert, a hen's nest full of eggs was discovered beneath the ruins of the ancient building. These eggs were twelve hundred years old, and were about to be thrown away by the labourers, when the Abbé, remembering that wheat had been grown from grain found in Egypt in mummies dated back from the time of the Pharaohs, bethought him that possibly there might still be life in these eggs. A *savant* of the Institute, consulted at once in reference to these precious relics of an age when there was as yet no France to detest "perfidious Albion" or to be jealous of Prussia and needle-guns, advised they be forthwith confided to a hen of approved success in the maternal capacity. This advice having been acted upon, the good curé and his friends had the delight of witnessing, twenty-one days afterwards, the hatching of a fine brood of chickens, the direct progeny of the denizens of Dagobert's barnyard. The fowls thus obtained have been carefully kept from any *mésalliance* with their congeners of less ancient blood; and the Abbé has now a yard so well replenished with "King Dagobert's fowls" that he not only supplies his own larder with poultry of this illustrious breed, but is about to organise, at the suggestion of numerous friends, a sale of "King Dagobert's eggs" for the benefit of the poor of his parish.—(*National Agriculturist.*)

MR. BULLEN'S POUTERS AT HOME.

The name of Bullen is but a new one among exhibitors of fancy Pigeons, but it has come very frequently to the front the last few years. Still, although new as an exhibitor, Mr. Bullen has, to use his own words, "been a Pouter fancier his whole life." When I found that a Bath clergyman had taken high honours with his Pouters at such Shows as the Crystal Palace, Bath, and Bristol, &c., I felt a great curiosity to see how he, a resident in Bath, managed to keep his birds. Hitherto among English amateurs of higher social position I had always, and I think only, known clergymen and other gentlemen as country dwellers; but here was one who resides in Bath, not in a villa near, but actually in the city of Bath—close to historic Pultney Street, and who keeps his Pigeons there, and is yet a successful exhibitor. Offering a visit to Mr. Bullen when meeting him at the Pigeon fanciers' levee, the Crystal Palace Show, an offer kindly accepted, I wended my way one day last winter (what a comfort to be able at length to talk of the winter as being past!) to Edward Street, Bath, where Mr. Bullen resides.

The Pouter, as most of my readers know, requires quite different treatment to any other Pigeon. Like a baby, if he is shy he is not worth looking at; and as a baby must see company, and be talked to, and drawn out, so must a Pouter. He must be familiar to sauciness; far from being afraid of you, be pleased and proud to make your acquaintance. In short, he must be made a companion of in order to be companionable. To achieve all this and keep his birds in show Mr. Bullen has given up a room in his house to them—a room looking to the back, which with another tenant would have been the housekeeper's room. Here live the Pouters in state, in pens of goodly proportions; and through the opened window they can pass into a wired enclosure, the whole space of a town garden being appropriated for their flight. Surely no city-living Pouters were ever better cared for. The room immediately below the one in which live the Ponters—a cellar in fact—is occupied by the feeders, which also have their place of flight as well. These feeders are good-sized Runts, their size being kept up by an occasional cross with a prize bird. These good-tempered big Pigeons—(big people are generally very easy and kindly, in contrast to fiery little folks)—Mr. Bullen finds the best of feeders, giving an abundant supply of food, and so much better than the birds recommended for feeders by the old books—viz., Dragoons. These, like their great uncles the Carriers, are a very quarrelsome variety; and then with such a dagger of bill a Dragoon is a powerfully armed foe, and can rip up a poor helpless bloated Pouter as easily as a Roman soldier did a bearded Jew at the seige of Jerusalem—holding the Jew by the beard, and using his straight, piercing, dagger-like sword. Poor helpless Pouters! at the mercy wholly of the fighting well-armed Dragoon. But the kindly portly

Runts, perfect monthly-nurses in feathers, see well after the Pouter babies and do not injure their parents.

Now, good readers, let us in thought enter what I will call Mr. Bullen's Pouters' parlour, for a papered room in a Bath house is too good to be called a Pigeon loft. Around at a suitable height for inspection—that is, about the height of a table, are arranged the spacious pens in which at the time I saw them the birds were confined. Some of the pens are made of smooth round bars of wood; these Mr. Bullen prefers, as they, unlike the wire, cannot injure a feather. Others are of the usual wire, but of different shapes and sizes. Mr. Bullen keeps his birds warm—this is a great point—and they are healthy. The food usually given is peas and tares, in the show season Indian corn and beans. Sand and gravel are at hand. The sexes are separated in the winter season, a plan which is, I believe, on the whole the best. I forgot to mention that the pens are 22 inches in height, and 2 feet broad and deep. An open space is in the middle of the Pouter parlour.

Now let me mention some of the occupants of the pens. There is the Black cock first and cup at the Bath Show, with rose pinion of great beauty, with Black hen for mate: these are a splendid pair. Then came a fine Blue pair, hen quite a young thing, but such a globe and limb! A White cock, again, of very great beauty, and a Black cock of wondrous metallic plumage. There is, too, the Palace first-prize hen and the Oxford Blue hen. Mr. Bullen started this season with well-matched birds for breeding—four pairs of Blues, two Blacks and one White, also a Yellow cock and Red hen. Here were the chosen birds to produce progeny for future triumphs.

All men have not a turn for Pigeons, but those who have and are compelled by profession to reside in a city, may take example by Mr. Bullen and see how they can utilise their space and have and enjoy their pets. I could not help noticing anon, what I had often noticed before, how different to all other Pigeons is the Pouter. Not alone his upright, man-like form—for this bird does stand up like a man and look at you—but how unlike other Pigeons he is in gesture and bearing. They as a rule are little flyaway birds; he stands, and stares, and struts near you. How companionable the fellow is; what a social fellow he is; how much more there is in him than in others. He keeps one from being dull, for you cannot feel alone in his company. Mr. Bullen's "Pouter parlour" is a great success, so is his cellar full of Runts. By the way, how Sir Wilfred Lawson would rejoice in such a use of a wine-cellar. Softly-cooing, loving Pigeons" he would say, "where once lay, like drunkards, the full bottles." I think he would introduce Mr. Bullen's cellar to the notice even of the House of Commons. I have heard of a clergyman who said he used to go out and thin his grapes between the heads of his sermon. Perhaps Mr. Bullen finds petting his Pouters equally useful, and after a run into his "Pouter parlour," there come to his mind and pen

"Thoughts that breathe, and words that burn."

I wish Mr. Bullen every success with his birds, and am glad indeed to see another exhibitor of the noblest of Pigeons take a deservedly high place at our exhibitions. I had seen Mr. Bullen's Pouters abroad, and was even more pleased to see them "at home."—Wiltshire Rector.

ENGLISH OWLS.

I wish to say a few more words in answer to "Wiltshire Rector." I uphold that I was entirely right in the reading of Moore's remarks on the Owl, that when he says that in "make and shape" it is like the Turbit he means thereby that in "make" it is of the same size, in "shape" of the same outline. I can easily see that there may be diametrically opposed opinions on Moore's words, and they caused me a good deal of thinking before I gave my opinion of them, but what decided me was the fact of his using two words together that at first reading appear synonymous. Had he used "make" only I would have thought he meant to indicate shape or outline, but putting it as "make and shape" I feel sure he meant to imply that both in size and lines the Owl of his day was like the Turbit. Mayor evidently thought so also.

The Rector next speaks of climate influencing size, and mentions Indian Fantails. I have not time to go thoroughly into this matter at present, but will merely say the Scotch Fantail may have been bred smaller since Scotchmen took him in hand, and there may be in India Fantails not half as big as other Fantails there, and all sorts of sizes in between. I can assure the Rector that in India there are as big and as little Pigeons as there are in this country, and that it is the breeder's art and not the climate that has made them so. Wild, or semi-wild Blue, Blue-chequered, and Mealy Pigeons in India are exactly similar in size to their congeners in the north of Scotland.

The Powdered Owl is a pretty bird and will have admirers, notwithstanding what may be written against him. He is not pure bred, however; he is either crossed or has degenerated into coarseness. That is quite apparent when he is put side by side with only a fair specimen of the African Owl.

In conclusion, I shall be very glad to acknowledge any mistakes I may make when convinced of them, but the Rector will excuse me if I cannot see so clearly as he seems to do. His remarks on "make and shape" do not at all agree with my ideas. I think he stretches words to suit his case. I leave Moore's words to be rendered by others.—J. C. Lyell.

[This controversy may now be closed.—Eds.]

SELECTION.

So many inquiries reaching me referring to the art of selecting birds for breeding, have induced me to throw into form the results of my theories and experiments. Without argument or any intention of arguing, I shall say I firmly believe that all the varieties of Pigeons have descended from one original source; therefore, to my mind, the breeding of Pouters, Carriers, Fantails, &c., from the common Pigeon is a simple fact in nature, depending upon selection extended over a period of time. Having satisfied myself with regard to the truth of the general principle, the minor changes and differences, such as those of colour (as among Toys), beak (as among Carriers and Barbs), shape and heads become easy problems, the truth of which can be demonstrated, and is demonstrated every day, in the lofts of every Pigeon fancier.

It is not necessary for one to be told when he sees smoke there is always fire; he knows that, because in his experience fire is always the cause of smoke; so when one sees a key it suggests the lock. Now, in all the varieties of Pigeons one recognises all the parts of the common Pigeon, and not only do we recognise the parts, but, as at school we used to do our sums backwards to prove them, so do all the varieties gradually recede or degenerate into the common Pigeon when neglected by the power that selected and stamped them as varieties, thus proving themselves descendants of the commons. Pouters become smaller and smaller when allowed to intermingle, Carriers lose in wattle and size, Fantails drop their tails, and Tumblers become coarse.

Thus believing, I see numerous possibilities, and have, by direct experiment, satisfied myself and friends with regard to many of them. That all the Toys are but modifications of colour applied to the common white bird is evident to anyone, as is the application of the key to the lock; and there is not so much difference in the markings as one would suppose at first sight; for instance, the Spot, Helmet, Swallow, Nun, and Magpie all have black heads in easy gradation one to the other. The Spot, Helmet, Nun, and Magpie have black tails; the Swallow's tail has become white; while it, the Helmet (until lately) and Nun retain the black wings. The Owl, Turbit, and Jacobin are also not many removes from the common, though the heads and bills are more evident departures than the mere colouring. As we reach the high fancies the differences become more extravagant, and in the wattled birds we see the beak of the common greatly enlarged, as is also the cere of the eye. The head is moulded to a long and narrow form, or shortened and thickened. In the Pouter we see the common enlarged in all its proportions, as in the Tumbler it is diminished. We know that these removes from the common specimen are the products of mankind by the evidence (history) of the last hundred years, and by the changes in colour, shape, and size that accumulate in everyone's loft, and that need but a little encouragement to bloom into new varieties.

Colour is the easiest of all distinctions to fix. Five or six years will enable one to obtain almost any marking he wishes. And I will give an illustration of one thing I have done within the last few years: I wished to obtain white Fantails with black tails, and there was no way but to breed them. I first crossed with the Nun, and spent several years manipulating the crosses, but without obtaining satisfaction. Some of the birds were fair, and if I had been patient I should have obtained all that was wished; but steaming ahead in true American style, I found a sport in a friend's loft; it was a black hen with white breast and head. This bird was procured and matched to a fine white cock, and their young were white, black, or speckled, with now and then one with the colours nearly where I wished them. Those which were nearly perfect were matched together, and my efforts were to have the line of division between the white and black as near the tail coverts as possible, and to prevent foul feathers appearing. The fouls were tenacious, and it was some time before I got rid of them and succeeded in breeding a perfect bird. Had I continued with the first lot there would not have been so many foul feathers to contend against; but the carriage would have had to be carefully bred for; as it was, the birds were much admired, and were a source of satisfaction as long as they were in my possession, not so much because of their rarity as because they were the products of an experiment that was much laughed at by knowing fanciers, who invariably predicted failure. I also started a strain from a couple of sports, from yellow and white stock, afterwards discovering a snell ancestry.

To change a physical conformatio requires more time and

much patience. The beak and wattle of the Carrier, for instance. is theproduct of many years, the greater part of which was lost, by gropings in the dark; and I think from what I know that fanciers of the present day could develope by selection and matching from ordinary wattled birds two distinct strains, Long-faced and Short-faced Barbs, that in a moderate period of time could rank with either the Carriers or Barbs that have been the products of the last century. At the time Moore wrote the beak of the Carrier was good at 1¼ inch. The haphazard selection of fanciers has increased it, and birds with 2-inch beaks are at present the standard. Now, it was much harder to add that last half inch than to produce all the other distinctions of the head as they existed in Moore's time, and the last sixteenth of an inch was more difficult to produce than any half inch nearer the skull; yet all this has been done almost in our day, and proves by analogy what a scientific fancier guided by the light thrown by the development of species can do. The beak of the Barb is not much shorter than that of the ordinary Carrier of Moore's time. Many of the coarse birds we see will measure from 1 inch to 1¼ inch, yet they are called Barbs because of the down face, all the other conformations belonging to and being identical with the Carrier. Desirous of satisfying myself with regard to the possibility of developing the Carrier and the Barb from the same forefathers, I once instituted a series of experiments. The increase of the Carrier's beak from the common's beak of 1 inch to the high fancy beak of 2 inches is a problem, to prove one part of which necessitates the acceptance of the whole, and so of the diminution and change of outline of the Barbs. Wishing to simplify my labour I bought a pair of ordinary barbed birds, the beak of the cock being 1¼ inch, and that of the hen a little less in length.

From the young of these I selected three lots, the largest best-wattled for a strain of Carriers, the smallest for Barbs, the others to breed back to commons; the last were allowed to fly, but not to mingle with commons or others. My experiment was interfered with by circumstances over which I had no control, but not before I had obtained the following results: the average length of beak in the first lot was increased a full eighth. I bred a great number of this lot, and crossed as far apart as I could, knowing it was the hardest part of the problem. The second lot was interbred as closely as could be, and a refined-looking wattled bird with small beak was the result, a much better appearing Barb than most of those we see. The flying lot became Dragoons (on the road to commons), as all wattled birds do when allowed to care for themselves. Here were three lots of birds springing from the same parents, presenting at the end of a few years distinctions enough to entitle them to be marked under three different names, and these changes caused by the selection and matching of specimens possessing certain properties.

I was perfectly satisfied with my experiment, and accepted the result as the solution of the question, Were Barbs and Carriers offspring of the same ancestors? Anyone desirous of satisfying himself with regard to the system of philosophy now paramount in the realm of thought would do well to institute some such experiments as here detailed. Do not take for granted all that is said for or against the theory that variation and selection are the origin of varieties, and through them to species; but test some part of the hypothesis for yourself, and judge calmly and decidedly of the evidence. Words are of little use for or against, and philosophers may wrangle or fanatics fulminate, as Nature, regardless of their word-wisdom, lays at their feet proof after proof of their blindness.

A pleasant experiment of what may be done by selection would be the improvement of Barbs. In the first place determine the points to be bred for, then select the strains approaching nearest, and give yourself up to the full enjoyment of a partnership with nature. The points are, short, broad, and down beak, broad head, well wattled eye, slender neck, and small size (see August number of *Bulletin*). You have a pair of well-wattled Barbs. Should you breed in-and-in or not? Suppose we say no, and take, in preference to in-and-in breeding, the liberty of crossing with Tumblers. There is a variety of small yellow Tumblers that is not a long remove from the Barb which can be used; but the best crosses are with coarse specimens of the Short-faced Tumblers, that variety having the slender neck, broad head, and small body which is desired in the Barb. Match the cock Barb with the Tumbler hen, and *vice versâ*. From the young of these two pairs select those which show the most Barb characteristics attached to the smallest bodies, breed some of them together, and then match a pair of the smallest most Barb-like young (grandchildren) with the old Barbs if necessary, to increase the wattle, which may be partially lost. Or, if you have a good strain of Barbs, you can introduce one Tumbler, and cross its progeny with the rest of the Barbs, and after a year or two repeat, until the size is obtained without any material loss of wattle or time.

Hundreds of experiments can be suggested whereby one, so aspiring, can improve one's knowledge; but, as nature is an open book, of which life teaches us the vocabulary, we suspect fanciers will soon read its columns more intently, and look at the pictures less, thereby finding elements for their own experiments.—Dr. W. P. Morgan, *Baltimore, Md.*—(*The Pet-Stock Bulletin.*)

[This is a very high-class article of Dr. Morgan's, and raises the fancy into more scientific atmosphere than usual. I am glad to find that Dr. Morgan accepts the scriptural account of Pigeons being descended from one original pair. In this he is also confirmed by Darwin, whose experiments went to prove this true. Recently I saw two stuffed specimens of Barbs, which were at least forty years old. They were the property of a very aged fancier now deceased. Being under glass they were in a good state of preservation, and are wonderfully long in face—quite as long as the Barb represented in Girton's "Pigeon Fancyer." On seeing them I could not help thinking that the Carrier and Barb are nearer cousins than many imagine. One of the two stuffed specimens had a tuft at the back of the head, as was usual some years ago, and gave the bird a jaunty look, which was to my eye pleasing, though detrimental to the effect of the peculiar shape of head required in the Barb.—Wiltshire Rector.]

LONDON FANCY CANARIES.—No. 3.

As I have before mentioned, "London Fancy" birds much resemble "Lizard" birds in their nestling feathers, and possess in the like manner either perfect or broken caps. If a "Lizard" bird has a broken cap that defect cannot be obviated by the moult; the blemish will be apparent during life. If a "London Fancy" bird possesses a broken cap in its nest feathers, it is no bar to its being exhibited when having passed through the moulting process. All appearance of defective cap is lost when the body feathers become clean or light. This marked difference has ever led me to believe that the "London Fancy" is a distinct variety, and is not a made-up bird through crossing-in with "Lizard" and "Norwich," as many fanciers suppose and have asserted the same to me. I know well what the crosses are betwixt either breed. The young certainly make handsome cage birds, but to breed pure "Fancies" or "Lizards," pure stock must be bred from.

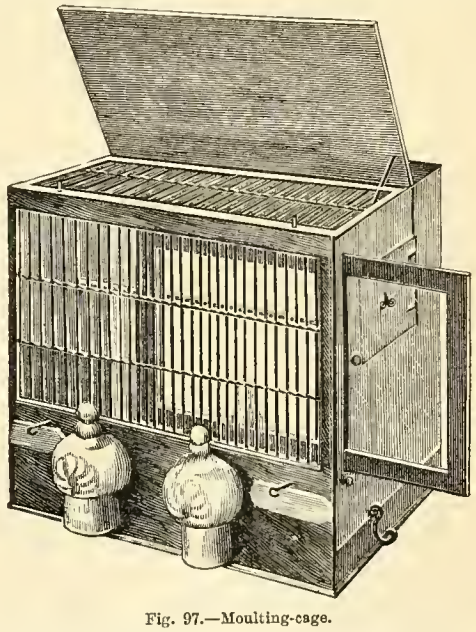

Fig. 97.—Moulting-cage.

When young "Fancy" birds have attained the ages of six or seven weeks they should be caged-off separately in the box moulting-cages, in which they will remain until they have entirely finished moulting. If the birds are not moulted singly they will very likely pluck each other, and the feathers will grow-up dark or ticked, which are considered blemishes in exhibition specimens.

Each moulting-cage should be furnished with water and seed-fountains, with a couple of perches inside the cage, one across the centre of the cage, and the other in the same direction, only lower down near the front of the cage where the bird partakes of food. Be sure the perches do not cross each other. A couple of slide-tins for the food should likewise be provided, and should be inserted in apertures in front of the cage. In these tins are to be daily provided a continuous supply of egg and savoy cake (finger-biscuits), during the whole of the moulting period. Use only the yolk of the egg with the cake, which can be prepared

for the birds by first pressing it through a sieve and then mixing the two ingredients together in a piece of parchment about a foot square, which can be kept in company with the sieve in some handy place for use each time they may be required. This way of preparing the food is preferable to chopping it with a knife.

The cages I have used for moulting my "Fancy" birds in are of London pattern; in fact, they originally belonged to a fancier named Boakes, and were obtained for me by a noted breeder named Hook, of Walworth, Surrey, from whom I obtained a wrinkle or two in the mysteries of "London Fancy" birdology, especially the moulting and washing processes. I was a Lizard breeder to some extent at that time, and my friend and myself entered into a reciprocity treaty to exchange bird notes, and not only this, but I inducted a real bird enthusiast in Derby named Orme (father of the present exhibitor), into the London Fancy school. The fanciers I have above referred to died long since.

In shape the moulting-cages are mostly about 1 foot square, excepting when they are extended in length with a mid-partition for holding a couple of birds. Single cages, however, are much handier. The wood of which they are constructed is mostly of mahogany, the hard close kind is preferable to softer wood, which is more porous. Much taste is often exercised in the construction of the moulting-cages, some of which are beautifully inlaid with fancy wood about the front parts. I have a couple by me prettily inlaid and veneered. One-half of the roof or top part of each cage is made to open or lift-up, beneath which is a wired frame to fit the aperture used when the lid is up for the purpose of examining the birds during the various stages of the moult.

The front of each moulting-cage should be closely wired, there not being above half the space betwixt each wire as in a show-cage. There is a necessity for the close wiring, for if when drawing a glass slide which extends along the inner side of the wire front, and again closing-in the slide, a bird should by chance protrude its head between the wires, an accident might soon occur. The close wiring prevents this.

As the young "Fancy" bird becomes more habituated to the moulting-cage, the glass slide is gradually closed. When the bird has attained the age of sixteen or eighteen weeks, and has been well attended to with the egg and cake, and the cage during the time kept well closed, a bird bearing a beautiful rich plumage—very different to that it bore when first introduced—will be found. Every attention must be devoted, for neglect of food will tend to keep back the bird, and the food must be fresh daily, and care taken that the tins be occasionally scalded and kept scrupulously clean. Great care must be exercised when cleaning-out the cages, for the displacement of a dark wing or tail feather will tend to somewhat deteriorate a bird for show. The least the birds or cages are meddled with the better during the moult.

The introduction of the new pepper diet has induced some to adopt it for the sake of imparting more colour. I have always noticed in pure-bred high-class specimens of the "London Fancy" breed, a rich and beautiful silky virgin appearance of bloom, especially noticeable in the buff or mealy kind, but which to my thinking becomes somewhat marred when the birds have been moulted upon the cayenne diet. If the colour by the use of pepper is more intensified, still to my mind the general beauty of the bird is not improved. I know the idea with several fanciers of late has gained ground that if a bird can be brought to a certain pitch of colour, it is deemed all-sufficient to rank it as an A1 bird. This is a mistaken one-sided notion. There are other matters of vast importance. Quality of feather, purity of blood, and elegance of shape, must not be lost sight of, for if the breeders in general lose sight of selecting proper specimens for breeding purposes, and judges lack in all other considerations but high colour, then the fancy will be taking a retrograde movement, and undoing that our forefathers have been aiming at—viz., "Improving the breed of Canaries." With cayenne-pepper-moulted birds colour much depends upon the quantity of pepper a bird swallows.

Just to show the restrictions placed upon breeders of the "London Fancy" birds, I quote the following rule from an old book of rules in my possession:—"Rule 13. That no member be permitted to feed his birds with anything but bread, egg, and savoy biscuits, all descriptions of seeds, and green meat of every kind; that no marigolds, saffron, or dye of any kind be permitted to be used on any pretence whatever, on pain of expulsion." Their chief aim evidently was, as stated on the title page of the book, "For promoting improvement and beauty in the breed of fancy Canary birds."

Experience of late has fully decided the matter in my mind, that a pair of birds for breeding purposes should be selected from stock not brought-up to a certain bright colour with pepper. —Geo. J. Barnesby.

SALEABLE HONEY.

It is one thing to raise honey and another thing to sell it, and with some persons the first process is often easiest. Now having in view the three announced apiarian exhibitions of this year I think a few words on this question will not be out of place. At the Crystal Palace last year, I am sorry to say, the greater part of the magnificent supers exhibited were returned to their owners unsold, for the simple reason that they were too large to carry away, as well as too costly, for most visitors would be honey buyers. In fact the smaller the super the more likely was it to be sold. The Americans, who are extensive honey-raisers, long ago discovered this, and have hit upon a contrivance by which their honey is brought to market in the most saleable form, and immense quantities are produced. The agricultural and bee-keeping journals teem with advertisements of wholesale honey-buyers. So it would be here. Let the honeycomb be sent to market in the most saleable form, and customers would be readily found, for nice clean well-filled honeycomb is duly appreciated by the wealthy classes, and 2*s.* or 2*s.* 6*d.* per lb. is not begrudged for it.

At the New York State Fair, we are told by the American "Bee Journal," that "the main strife among competitors seemed to be mostly on box honey, as to what style of box is best, all things taken into consideration. The variety and styles of packages attracted much attention, and as there were competitors from different parts of the State the display was not only attractive but practically instructive. Mr. Tennant's sample was in old style of boxes, and though of creditable appearance not quite up to present requirements, the packages being too large to bring highest market prices, so with Mr. Griswold's sample, nice honey, but not in shape to call purchasers' attention. Mr. Bettsinger's was in narrow sectional boxes, I believe the same as advertised and sold by himself and Mr. G. T. Wheeler, largely in use and known in New York State as Syracuse style. As Mr. Bettsinger's were nicely cased, they showed to the best advantage, and could be very convenient for retailing purposes, and Mr. Hadsall's sample hung in frames similar in size to Mr. Bettsinger's boxes, but not as tastily put up, yet well arranged to show all the merits in that way of getting surplus. Mr. C. R. Isham's boxes were wood tops and bottoms of any desired size and of any kind of timber, some polished off in fancy style, some merely planed smooth with glass sides and ends, held in place by angular bright tin corner pieces pronged to pass through the wood and clinch, making as strong and nice a box as could be desired by the most fastidious, and profitable to the seller as they can be manufactured, about as cheap as almost any style of glass box. Part of Mr. Isham's box was in small single-comb plate boxes 6½ by 2½ inches, and weighing about 2½ lbs. gross, the ends showing the pure liquid honey in cells built against the glass, while the sides gave a view of the white-capped comb in all its beauty and purity."

The first premium was awarded to the honey in the glass boxes above mentioned, and exhibited by Mr. C. R. Isham. I see Messrs. Neighbour & Son have already advertised a sectional super to supply the required need, and perhaps they or James Lee may be induced to place before us some like Mr. Isham's above described. Bee-keepers have abundance of ingenuity, and I have no doubt we shall find exhibited at our September show good marketable supers.

Now a few words on run honey. Much of that shown last year was very dark, made to appear still darker by being stored in green glass jars or bottles. White glass is not much more costly, and the extra expense will be amply repaid by increased sale. Remember, honey is to be eaten, and so should be put in an enticing form. The British Bee-keepers' Association hope for the benefit of bee-keepers to hold a honey fair, but I think it unreasonable to expect us to weigh up run honey by the pound, or cut out combs from large supers.—John Hunter, *Eaton Rise, Ealing.*

BEES REMOVING EGGS FROM ONE CELL TO ANOTHER.

For more than thirty years we have been telling bee-keepers that queens lay far more eggs than they set, or have time to set, and that working bees assist them in this work of distribution and setting. The statements made have been frequently disputed and doubted. The late Mr. Woodbury wrote me privately for evidence on the point, and last year even Mr. Lowe himself ventured to assert that bees do not remove eggs from cell to cell. When he made that assertion he was invited to call here and see for himself ample and satisfactory evidence of the fact that bees do remove and reset eggs. In another periodical we find a paragraph touching this question, which gives me pleasure to transcribe for the instruction of the readers of this Journal.

Mr. W. Bassano, Haden Cross, Old Hill, says, "Last year I made a four-comb nucleus for queen-raising, and for some reason the bees did not attempt to make a queen till the larvæ were too old. I then gave them a bit of comb with eggs, and again they did not care to make a queen. Disgusted with their improper conduct, I did not trouble with them for some weeks, when, having a spare combful of larvæ and eggs, I thought I would give them another chance, so introduced it into the middle of

the box. On looking at it next day, they had commenced several queen cells, and had carried the surplus eggs into the adjacent comb; not only into the cells on the side next to the brood comb, but also carrying an equal number into the cells on the other side, just as a queen having laid some eggs on one side of a comb, always (I believe) goes round and lays an equal number on the other side. No doubt for economy of heat. I was surprised, however, to find the workers carry the eggs so far, and show the same instinct in disposing of them as the queen does."

"Egg-carrying," says the editor in a note appended to Mr. Bassano's letter, "has frequently been observed, but is often disputed. We can, however, vouch for the fact."—A. Pettigrew.

HINTS FOR THE MANAGEMENT OF SMALL APIARIES.

One of the difficulties which at this time of year presents itself to persons who have as many stocks as they want, but who wish for the utmost produce of those stocks in the form of honey, arises from the natural inclination of bees to swarm. Now swarms are all very well for those who want them, but a real trouble and nuisance to a number of people who do not want them. Year after year the difficulty recurs. Everything goes well up to a certain point, and then all is changed. Here are three or four splendid hives as busy as possible, giving promise of no end of honey. Supers are put on in due time, they are being beautifully filled; another week and the rich spoil will be garnered. But, alas! off goes a swarm; every bee in that swarm has taken a good bellyful, and the super is perceptibly emptier and lighter than it was yesterday, and not full enough to be taken. What is to be done? What ought to have been done to prevent this disaster? for disaster it is most assuredly. If the swarm had not issued there would have been so many more bees at liberty to collect the honey which is sure to be abundant sooner or later; whereas now a larger number of the bees will be required to attend to the young brood of two nurseries, and much of the honey will be consumed in the new hive in making the combs, while the diminished population of the old stock will be consuming at a rapid rate the stores actually accumulated; and what if second and third swarms follow? Not to speak of the frequent loss of the prime swarm itself, although, as it was not wanted, its flight under the circumstances is almost a relief.

Now the picture I have drawn of a distressed bee-keeper is no uncommon one. It is the experience of a multitude of persons who love honey and long to produce it, who keep a few hives for the purpose, and often have no honey at all after years of patient waiting. Can nothing be done this present season to save them from disappointment?

First let us see what can be done to prevent swarming. Of course we cannot always prevent this. Some years bees will swarm in spite of all precautions. Still, no doubt, we can ordinarily prevent it. The remedy is simply to give the bees abundant space for breeding and storing honey, with ample room for comfortable egress and ingress, and facility of ventilation. For this purpose a gradual enlargement of the hive collaterally with a corresponding gradual enlargement of the entrance in the same direction would be found almost a specific against swarming. Neither ekes nor supers piled up on high are so successful in preventing swarming, because in both cases the heat rises, while the remoteness from the entrance of the upper regions, some 2 feet distant, makes it a very laborious and inconvenient matter for the bees to ventilate properly, not to speak of the trouble of climbing so high. I am not alluding to "collateral boxes" as they were called, such as were used and recommended by the late Mr. Nutt. Occasionally these answered very well, more often they failed utterly. I am speaking of one large hive, say 24 or 28 inches long, 12 inches wide, and 9 or 10 inches high, with sliding divisions, capable of being removed in the spring and replaced in the autumn. Such a hive is the nearest approach to, and yet an improvement on, one of the favourite localities selected by stray swarms—namely, between the joists and flooring of rooms which have a communication with the open air. If such hives were made with bar-frames, an exact adjustment of plunder and convenient supply of food and breeding combs could be made every autumn, when the contracting slides are replaced for the winter. The entrances to these hives should be capable of contraction and enlargement according to the season, and might range from 3 to 9 or 10 inches wide. Hives of this sort are yet to be constructed, as I am not aware of their ever having been tried.

But what of ordinary hives, how can these be prevented from swarming? The next best thing is to put on each a large flat super with plenty of space for easy communication, regardless of whether the queen breeds in them or not. The ordinary plan is to have the communications as small and narrow as possible, to prevent the queen from ascending and laying eggs in the supers. We should say to those bee-keepers for whom I am now writing, Never mind the queen ascending and spoiling the symmetry of your honeycomb. Some of it may not be quite so beautiful as you would like, but if honey abounds a large proportion of the comb will be as perfect as you could wish, and as to the rest the rearing of one batch of young bees in freshly made comb is but very slightly deteriorating. Anyhow what you lose in quality you will certainly gain in quantity, in fact you will have both quantity and quality in measure.

Suppose with all your care one of your stocks should swarm. We advise you to put it into a full-sized hive and set it in the place of the stock out of which it came. If you remove the old stock to a new temporary stand for a day or two, most of the full-grown bees in it when they fly abroad will return to the old stand and strengthen the swarm, which ought to become heavy, supposing it to be an early one. As for the old stock, now greatly weakened in population, it may be usefully employed in preventing the swarming of one of your other stocks, if you have any, instead of being treated in the usual way; for you can turn it up and after fumigating the bees with a little brown paper or fustian smoke, cut out every royal cell that you can see. This done we recommend you to place the stock as a super over one of your other stocks. It will be taken possession of immediately by the bees below, who will hatch out carefully all the young brood in the cells, and proceed to store honey in them after a thorough cleaning. If the combs should be older and blacker than those of the stock to which you propose to join them, we advise rather the reverse treatment. Place the swarmed and empty hive under the stock instead of over. By this means what honey you get will be stored in the fresher combs of the younger stock, and will be proportionately purer. This plan is largely adopted in America, and helps them to those enormous harvests of honey of which we read. Of course the honey will not be of first-rate quality, but by a judicious method of treatment by separating the cleaner and fresher combs from the rest and extracting the honey separately, a very profitable harvest will be obtained, some of it being very excellent honey.

Where common straw hives are used they can be almost indefinitely enlarged by the addition of supers or ekes. The eke is the surest preventive of swarming, but we would elevate the hive on a box of stout wood with several long parallel slits in the top—say a foot long and an inch wide. The depth and size of the box must be regulated by the season and the pasturage of the locality. Also the entrance must be large, and only at the lower part of the box. That in the old hive must be stopped up. —B. & W.

NEW BOOK.

A Manual of Bee-keeping. By J. Hunter, Honorary Secretary of the British Bee-keepers' Association. London: R. Hardwick.

Recently we had occasion to refer to all the English works that have been published on bee-keeping, and we found them amounting to more than fifty. First was "Profitable Instructions for the Perfect Ordering of Bees," and that was published almost three hundred years ago, for 1579 is the date on its title-page. Then we had before us Butler's "Feminine Monarchie," published in 1634, when Charles I. ruled the land, and which we notice only to observe that six years later, when Cromwell was Protector, John Day of Caius College, Cambridge, named his book "The Parliament of Bees;" and in 1655 Samuel Hartlib, yielding still further to political expediency, designated his volume "The Reformed Parliament of Bees!" Passing over all the others, we will only observe that within years very recent we have had thoroughly practical works published on bee-keeping by such thorough apiarians as Bevan, Taylor, Woodbury, and Pettigrew—all good and all cheap; therefore we advise Mr. Hunter in the next edition of his book to erase from its preface this sentence, "I was acquainted with no work embracing the requisites of cheapness and completeness up to our present standard of knowledge." That Mr. Hunter's volume will soon reach to another edition we have no doubt, for it is a careful condensation well arranged of all the knowledge requisite for successful bee-keeping. He does not confine himself to the results of his own practice and observations, but candidly acknowledges that he has gathered—but always naming his authorities—whatever he knew would help the novice "on the road to profitable bee-keeping in a merciful and rational manner."

Every arrangement, every need, every operation is separately considered in thirty-six sections. We will enable our readers to judge for themselves by quoting one, because it is the shortest.

"Robbing.—'Honesty is the best policy,' but bees seem to think the contrary, and 'might gives right' is a proverb more often acted upon by them. Should a hive become weak, and especially if queenless, as soon as the state of affairs be discovered by a neighbouring strong family, a raid is organised. Poor bees! gallantly do they defend their stores, and great the slaughter that ensues but numerical strength is sure to conquer. When the assailed are fully assured that resistance is in vain, they act very wisely, and instead of fighting longer, turn to and help the invaders to carry off the stores, and in reward are re-

ceived as new citizens in the freebooting hive. If a hive which is known to be weak be discovered in a state of unusual bustle and excitement, watch it narrowly; and if fighting be going on nearly close up the entrance for a few days, leaving room only for one or two bees to pass at a time; a narrow door is more easily defended than a wide open gate. Should the assailants be very pertinacious, wet a piece of tow or moss with carbolic acid, and fasteu it on the alighting board; the robbers will be too disgusted to pass, but the defenders will brave it. Fighting may often be ascribed to the bee-keeper's carelessness in spilling honey or syrup round about a weak stock, which being discovered and appropriated by stronger bees, they soon seek for more plunder in the same locality. The Rev. Mr. Kleine says robbers may be repelled by imparting to the hive some intensely powerful and unaccustomed odour. He effects this by placing in it in the evening a small portion of musk, and on the following morning the bees, if they have a healthy queen, will boldly meet their assailants. These are nonplussed by the unwonted odour; and if any of them enter the hive and carry off some of the coveted booty, on their return home, having a strange smell, they will be killed by their own household."

The volume is illustrated by many well-executed woodcuts.

OUR LETTER BOX.

Eggs (*C. A. G.*).—The notes you refer to did not mention any names, and we think it would not be advisable to publish an index to them. Moreover, it would lead to pleas and rejoinders for which we could not afford space.

Detecting Sex of Eggs (*J. T. G.*).—The knowledge you crave has been sought for many years. Many have been convinced they had acquired it till they put it to the test. The theory was that the pointed eggs produce cocks, and the round eggs pullets. We do not believe in it. We have tried for years, and the only result we can arrive at is that we believe the early-laid eggs of a sitting produce more cocks than the later ones; even this, we believe, is uncertain, but it has proved right with us sometimes.

Unusual Length of Hatching-time (*R.*).—We cannot explain why it is, but in hatching largely we have frequently twenty-four hours between the first and last chickens coming out. Such being the case, there is no reason why the time may not be somewhat extended. We are careful to remove the shells, and leave the chickens till all are out. If we were to put Spanish, Cochins, and Brahmas together, we should expect the Spanish out first from the thin shells.

Chickens Dead in the Egg (*L. G. L.*).—In all cases sitting eggs should be thoroughly damped for some days before they hatch. When this is not done, especially when the wind is in the east, the egg becomes unnaturally dry, and the inner membrane so tough that the chicken cannot make its exit. Its little strength is wasted in vain endeavours to break out. If the eggs were wetted daily for ten days before hatching time this could not happen. It may be done when the hen is off. The hands should be dipped in cold water, and then wrung several times over the eggs. It is merely following Nature. All birds leave their nests at daybreak in search of food. The grass then is wet with dew, often with white frost, sometimes from rain. The hens return to their eggs reeking with wet. They always hatch, and so will yours probably if you use like precaution.

Detecting Fertilised Eggs (*S. E.*).—We cannot help you, the fertility of an egg can be only discerned after a change has taken place, and life begins to be developed. It can be seen after the egg has been five or six days under the hen. Choose a dark outhouse on a sunny day, close the door all but a streak of light, make a telescope of the hand, place the egg at the end farthest from the eye, bring it in a direct line between the sun and the eye, and an irregular dark streak will be plainly visible, showing the change has begun. Where there is no change the egg is not impregnated.

Cooking Eggs Soft.—I learnt the following mode at Queen's, Oxford. Have a tin boiler with a coverlid. Boil the water and put in the egg for six minutes, and take the boiler off the fire as soon as you put in the egg. The reader will be surprised at how good the white is when so cooked. It is as good as the interior. Usually the white is as hard as a board, tasteless, and indigestible.—W. F. Radclyffe.

Canary Breeding (*C. S., Liverpool*).—Canary breeding cannot be carried on to such advantage when the space is limited, or the breeding compartments are not advantageously constructed, and especially when the first broods cannot be separated from the old hens while sitting their next nests of eggs. Where only one nest is provided it is a natural consequence that the eggs may become soiled and spoiled by the shifty young birds, who for a time prefer crowding about the old nest quarters. It is rarely young Canaries leave the nest before they are seventeen or eighteen days old, and by sending the hen again to nest (when the young are a fortnight old), in another part of the compartment away from the young, the eggs will neither be disturbed or soiled. But even if the hen lays her second lot of eggs in the nest where the young brood may be, each egg can be taken out and kept in bran or fine sand until the whole, or at least four of them are laid, when they can be replaced in a clean nest in the cage for the hen to sit upon. The young birds by this time will be on the turn of three weeks old, and if, when you return the nest with the eggs in, you find the young interfering with or annoying the old hen, at once partition or cage them off with the cock bird, who will bring them up and learn them to feed in a day or two. Our plan is when the young Canaries have attained the age of twelve days, to introduce into the breeding compartment a duplicate box or basket with the nest half made, and some nesting material for the hen to put the finishing stroke to. We take care that there be two hooks or nails in different parts of the cage for hanging the boxes on. We transfer the nest with the young on to the other nail, and in its place suspend the clean nest. Most hens like their old breeding quarters. The hens will be laying and no doubt commencing to sit before the first brood have left the nest, and will escape much of the annoyance they are subject to when only one nest is used. Most hens when nesting again, or sitting their eggs in another part from where the young birds are, will chastise their offspring if inquisitive or annoying. There is another advantage (which we look upon as a part of good management), and that is if you send the hens to nest earlier than they would otherwise go, if having to cope with a nest of fidgetty young birds, which have to leave the nest before the hen can well settle down to sitting, the probability will be that one-half the feathers will be stripped off or plucked by the hen, who will line her nest with the same. Now, what can be more annoying than to have what the "fancy" call their "plums" mutilated in this way, and the second feathers shooting forth before art can step in to assist Nature? Pepper and every other artificial mode of operation would then be of no avail.

The Seed Question (*Note*).—For the further information of Canary fanciers, we may state that we have not used one grain of canary seed for the past month. For canary seed we have substituted white millet.

Preserving Peas Green (*F. J.*).—Pick them when full grown, shell them dry them gently but thoroughly, and then store them in canvas bags in a dry place. When required for use soak them in water for a few hours until plumped-up, and then boil them. The following mode has been reported to us by a person well qualified to judge of such matters as being very successful:—Carefully shell the peas, then put them in tin canisters, not too large; put in a small piece of alum, about the size of a horsebean, to a pint of peas. When the canister is full of peas fill up the interstices with water, and solder on the lid perfectly air tight, and boil the canister for about twenty minutes; then remove them to a cool place, and they will be found in January but little inferior to fresh newly-gathered peas. Bottling is not so good—at least, we have not found it so; the air gets in, the liquid turns sour, and the peas acquire a bad taste.

Straw Super (*W. F. Clark*).—As soon as the straw hive on the top of the empty bar-frame hive is full of bees, they will commence to build combs in the bar-frame one, and may fill it with combs before they swarm; but sometimes bees so treated swarm before the nadir is filled. If you were to remove the frame hive and put a super on the top the bees might swarm then. Nadirs are more likely to prevent swarming than supers. Your better way will be to let it remain as it is for a month, or swarm it artificially when it is ready. At present it is not strong enough to occupy both top and bottom hives.

REMARKS.

12th.—A very fine pleasant enjoyable day. [pleasant.

13th.—Rather hazy morning; a very fine day, but rather too warm to be

14th.—Very fine day; rather stormy-looking about 7 P.M., but clear by 9.

15th.—A very beautiful day, very warm in the middle of the day; but rather cloudy in the evening, though soon clearing off.

16th.—Fine morning; and all day fair and pleasant; the evening very much cooler, in fact quite cool. [7 and 8 P.M., but fine after.

17th.—A very bright pleasant day, with cool breeze; rather cloudy between

18th.—Slightly cloudy day; a little rain just after noon, and again about 7 P.M., in each case preceded and accompanied by violent gusts of wind.

A week of pleasant weather, bright and dry, and though the mean temperature is about 7° above that of last week, only one day on which it was too warm to be agreeable.—G. J. Symons.

COVENT GARDEN MARKET.—May 19.

The supply is well kept up; business, however, somewhat interrupted by the holidays. The French goods have not come so well during the last few days owing to the unusual heat of the weather.

From observations taken near London during forty-three years, the average day temperature of the week is 68.1°; and its night temperature 44.8°.

AURICULAS: SHOWING AND GROWING.

HAVE perused with much pleasure the notices of Auricula shows, and also the remarks on exhibiting them in the recent numbers of the *Journal of Horticulture*. It was very pleasing to read of the success of the National at Manchester. However, there are, perhaps, some things in connection with the Show and the manner of exhibiting the plants that might be criticised with advantage.

First as to the remarks of "An Old Fancier" at page 364. He thinks it either wrong or in bad taste to place sticks to the trusses to hold them in an upright position; but it is very plain that if the Auricula is to receive the support of the general public the groups of plants must be effective. Now, I was not at Manchester, but was told that the effect of the Exhibition was spoiled, not so much by the dark room, but owing to the trusses falling about in all directions for the want of supports, and that the visitors might be seen to take hold of a prize-truss and hold its head up to see what the pips were like. If the stem is of the strongest description ten to one but it will grow naturally in a slanting position from one side, while the truss on the next plant may shoot off at an angle of 45° in another direction; whereas a neat stick that is scarcely seen would support all the trusses in one position.

Another objection to showing the trusses without supports is the time required to unstick the plants just before the show, and to place them to the trusses again at night. This may only seem a small matter to a grower who can bring his stock of plants in a basket on his head. I exhibited about six dozen plants at the Royal Botanic Gardens; to reach there we had to be up at 3.15 A.M., and travel behind a slow horse over a dozen miles, arriving at the gardens at little after eight o'clock; then all the trusses had to be arranged, and the pots placed where the plants were seen to the best advantage, and all to be done in a crowd of people whose only object seems to be to block the limited pathway. There is quite enough to do without untying the trusses. I have tried both ways, and I find there is a great difference between doing the work and criticising that of others. I do hope the clause suggested by "An Old Fancier" will not be put into the schedule of the Metropolitan Floral Society.

The suggestion made by Mr. Tymons about increasing the minimum number of pips from three to five I consider a good one. An Auricula with a truss containing less than five pips ought not to be taken to a flower show. Five is the minimum of the Metropolitan Floral Society. I was informed that the truss of Catherina (Summerscales) that gained the premium prize at Manchester had been cut away to three pips, each of them about the size of a silver threepenny coin or a shirt-button. The second best was about the same; while trusses of Glory (Taylor), Smiling Beauty (Heap), Omega (Turner), and True Briton (Hepworth), were left far behind. Now this is all very well in the rigid, and maybe correct, judgment of the old growers, but if this fine old flower is to become popular these old rules must be somewhat relaxed.

Then on the point of ground or body colour, why should black be preferred and all the other beautiful shades be designated "chancy?" Any other ground colour would have no chance to gain a prize in Lancashire judgment, unless a special class were to be provided for such flowers as Colonel Champneys (Turner), Marie and Sophia (Chapman), &c. Even Champion (Page) would be faulty in the eyes of a Lancashire grower.

Just a word or two on culture. Now is the best time to repot. This must be carefully done, and the plants must be kept free from green fly either by brushing it off or by fumigating with tobacco smoke. The plants must also receive plenty of air; the lights ought to be removed night and day at present. "D., *Deal*," on page 347, has said I brought my plants on by placing them in the greenhouse. Only a very few plants were forwarded in this way. The warm night temperature draws the trusses and bleaches the tubes. The Auricula will not bear forcing.

Mr. Peter Campbell of Graham's Road, Falkirk, N.B., sent me a box of blooms over which "D., *Deal*," Mr. Ball of Slough, Mr. James of Isleworth, and myself sat in judgment. Amongst them were a yellow self with green foliage, and a crimson self with green foliage. Three varieties were thought of the highest merit—viz., a blue-black self bearing some resemblance to Mrs. Smith (Smith), but much superior in form, substance, and paste; a white-edge flower had a very refined edge, the white being very pure; and a green-edged flower, the edge very pure olive green, superior to Admiral Napier by the same raiser. The paste of the Admiral is angular, the new sort has circular paste.—J. Douglas.

FRAGRANT ROSES.

It is a matter of some importance to all true lovers of the Rose that raisers should not lose sight of a great desideratum in Roses, and that is fragrance.

I am afraid, however, that this is the last qualification that Rose-fanciers consider, and if the raisers produce a Rose of first-rate form, good, distinct, and pure colour, strong growth and erect habit, they consider that they have deserved very well of their country, and that if the said Rose is quite destitute of fragrance the matter is of no consequence.

To a certain extent they judge rightly; for judges at exhibitions rarely, if ever, take the fragrance of the stand into account. I fancy I see the countenance of any of our leading judges (I do not like to mention names) if asked in the case of a disputed and difficult point of judging, to give the preference to the stand containing the most fragrant Roses! Yet, other qualities being equal, it would not be a bad way of deciding a vexed question.

I remember the Royal Horticultural Society once gave prizes to Roses to be judged by their perfume, and I have

still a catalogue in my possession where on the outer sheet the proprietor proudly informs the public that at this show he gained the first prize for "six Roses for smell;" but, alas! among other changes, notably that of refusing to pay the prize money, this is included, and the classes for perfume are withdrawn; so that there is now no encouragement to growers to cultivate Roses celebrated for their fragrance.

I remember once, at Hereford, the Marquis of Bute gave a £5 prize for twelve best York-and-Lancaster Roses, but the competition was so small that the committee persuaded him to transfer his prize to table decorations. So fragrant Roses are left out in the cold, and we live in hopes that some of the larger societies or wealthy amateurs will offer a prize for this class at one of the great exhibitions.

Now as to fragrant Roses. Here, again, by far the most superior is the Tea Rose, and if I am asked to name the most fragrant Rose I should say Devoniensis, and next place my own particular pets—Catherine Mermet and Madame Bravy, or Alba Rosea or Madame Sertot, as she is variously called Souvenir d'Elise, the most lovely of all Teas, has a most distinct and peculiar bouquet; it is really like fresh tea, and though not so pleasant as the first-named, yet is equally fragrant.

Maréchal Niel and Triomphe de Rennes possess great fragrance, while Madame Willermoz reminds one of most delicious fruit. This Rose, though rarely shown in perfection, is for fragrance almost unrivalled. Cloth of Gold is also very fragrant, and Rubens and Souvenir d'un Ami delight you with their perfume as well as charm you with their form. In fact, all the above-named Teas are good in every sense, and rarely, if ever, fail to bloom early and late.

Of the Hybrid Perpetuals it is difficult to give a list, as the great majority of this class possess most exquisite perfume; but I can name a few which are remarkably good. Général Jacqueminot among the dark Roses is pre-eminent for perfume, and La France among the lights. Abel Grand, too, is a most fragrant Rose, and that charming little button-hole Rose (which does remarkably well here), Boule de Neige, has a most sweet and distinct bouquet. Beauty of Waltham, among the light crimsons, is very fragrant, and Comtesse de Chabrillant among the light pinks. Madame Furtado, that poor weak grower, whom I almost despair of ever seeing in her beauty, is most celebrated for her perfume; and Charles Lefebvre, the grandest of dark Roses, is also very sweet.

The foregoing is a most imperfect list, but if I were to name all fragrant Roses I should want far too large a portion of your space; I have, therefore, only mentioned a few which in my opinion are most fragrant, and I hope other rosarians will supplement my list, and so make this letter the opening for another election of Roses—viz., those celebrated for their perfume.—John B. M. Camm.

[Sincerely pleased are we that an advocate for the fragrance of the Rose has ventured forth. We second all that he has said, but we are sufficiently ancient to remember Roses fifty years ago, and claim to be among the few inquired for in *The Saturday Review* who remember the scent of "the old Cabbage Rose." We delight in the fragrance of the Teas, but it is quite distinct from that of the Hybrid Perpetuals, and, indeed, that of all Roses which yield the true attar perfume. We have inhaled that perfume in the Rose gardens of the East, and testify that it is identical with that of the old Cabbage and Moss Roses. Why are these so neglected? Not one mentioned by Mr. Camm is equal and similar to them in fragrance.—Eds.]

QUEEN ONION.

In some notes on the crops of last year, which were published in the Journal in December, I called attention to the Queen Onion as a valuable early kind. Further experience has afforded such additional proof of its worth as to induce me to assign it a much higher position than I have hitherto done.

It is just about this time of the year that a hitch so often occurs in the Onion supply, the stored-up crop of the previous summer is exhausted, and really good new Onions of a useful size are not always forthcoming. To meet this want some seed of Red Mammoth, Tripoli, and Queen was sown July 15th, and the seedlings transplanted into one large bed September 5th.

Bearing in mind that the object in sowing the seed was to have a supply of Onions sufficiently large for kitchen purposes by, say, the first week in May, the condition of each kind at that time affords the best test of its merits; for however gigantic may be the proportions of Red Mammoth later in the season, if it is not larger than all other sorts when it is most wanted it is comparatively worthless. This was the condition of the two kinds at the time specified.

The Queen, sturdy yet with very slender stems, and fine bulbs 7 inches in circumference. Red Mammoth, very strong, coarse, and "bull-necked," with hardly any appearance of bulbing, the lower or thickest part having a circumference of about 4 inches. In future, therefore, preference will be given to the Queen, sowing the seed in the second week of July in the south, and a week earlier in the north, to obtain a full supply and prompt succession to the exhausted summer crop in spring.—Edward Luckhurst.

ROYAL HORTICULTURAL SOCIETY.

May 25th.

A special General Meeting of the Royal Horticultural Society was held last Tuesday in the Council-room, South Kensington, for the purpose of receiving a communication from the Council respecting the future prospects and condition of the Society, and to receive an answer to proposals made by the Council to Her Majesty's Commissioners. The chair was taken by the President of the Society, Viscount Bury. Amongst the members of Council present were Dr. Kellock, Sir Coutts Lindsay, Bart., Mr. Henry Webb, Mr. Little, Mr. Dobree (Treasurer), and the Hon. and Rev. J. T. Boscawen. Amongst the general body of the Fellows were Mr. W. Bull, Mr. G. F. Wilson, Mr. W. A. Lindsay (late Secretary to the Council), Mr. H. S. Godson, Dr. Masters, Mr. Shirley Hibberd, Mr. John Fraser, Dr. Denny, Dr. Pinches, Mr. W. E. Rendall, Mr. W. Pownall, Mr. Haughton, Sir Alfred Slade, Bart., Sir Alexander Gordon, Bart., Mr. Guedalla, Mr. Andrew Murray, &c. Several ladies were present.

Mr. Devonport, the Assistant Secretary, having read the advertisement convening the Meeting,

The Chairman rose and said that the first announcement he had to make was that of the resignation of their late Honorary Secretary (Mr. W. A. Lindsay). That resignation he had to submit to the meeting. In his resignation, Mr. Lindsay, while stating that he had taken considerable interest in the affairs of the Society, and took such steps as he thought likely to promote those interests, felt with deep regret that he could not agree with the policy of the Council or with the views of the President. Under these circumstances Mr. Lindsay thought it best for all parties to tender his resignation. It was for him (the Chairman) to ask the meeting for its confirmation of that resignation.

The Meeting confirmed it.

The Chairman again rose and said:—Ladies and Gentlemen, I now have to explain the position in which we at this moment are. My task, I regret to say, is an extremely easy one; it will be discharged in but a very few words. The result of it—the upshot, is to tell you that the Council, and we regret it, find it necessary to adjourn this Meeting for ten days. On the last occasion, ladies and gentlemen, you confided to us a certain trust, which was to make arrangements with Her Majesty's Commissioners for the future carrying on of the Society, and to submit to the Fellows a scheme for the future guidance and government of the Society. We hoped to have been prepared with such a scheme, but I regret to say time has been against us. The adjourned meeting to which I have referred was held on March the 9th, and it was not until the 16th of April we were able to obtain our first meeting with Her Majesty's Commissioners. That meeting, as I have said, was obtained on the 16th of April. Propositions were submitted by us which we had hoped would be acceptable to Her Majesty's Commissioners. Well, ladies and gentlemen, these propositions were not considered satisfactory. Then we amended our propositions on that, and, indeed, upon a subsequent occasion. At last we felt it was our duty to submit to you the circumstances under which we find ourselves placed, and I may say we were under the impression that a definite "yea" or "nay" would have been received from Her Majesty's Commissioners, and that we should have been able either to assure you we had entered into an agreement with Her Majesty's Commissioners, or that we had failed to do so. If the latter were the case, and we had failed to enter into and complete an arrangement with Her Majesty's Commissioners, we should have felt it our duty to say to you that under the circumstances it was due to our own honour—to ourselves, to resign into the hands of the Fellows the trust they had committed to us, and to beg of you to appoint in our stead those who perhaps might be more fortunate in dealing with Her Majesty's Commissioners [hear, hear]. Under those circumstances we summoned the present Meeting, believing, as we did, that before that Meeting was held a definite reply would have been received from Her Majesty's Commissioners to the last proposal—the last of six—which we have made. I do not now enter into the question of the refusal of Her Majesty's

Commissioners to entertain our proposals. That is a question I do not think it is now opportune to enter upon, because it will come up for discussion hereafter. I merely state the fact without prejudice to either party, and state it imputing blame to none [hear, hear]. We thought we would be in a position to give you definite information as to the future maintenance and conduct of the Society at this time, and under that impression we called this Meeting together. In the meantime we have received what we consider the definite answer of the Commissioners ——.

A Fellow.—When?

The Chairman.—About seven or eight days ago, but soon afterwards in that outside intimate conversation in which business is more often done than in more formal meetings, we understood Her Majesty's Commissioners did not fully comprehend the meaning of a part of our last proposal, and that it was not at all probable they might come to any decision. Gen. Scott was good enough to attend the last Meeting of our Council, about a week ago, and we then found the opinion of Her Majesty's Commissioners as to our last proposal was such as that a little longer time would bring us face to face with Her Majesty's Commissioners. I offer no opinion upon this, but, for my own part, I should feel more pleased if my honourable friends at the Council board and myself could say we had done all we could and that we resigned our trust into your hands [hear, hear]. But, the circumstances of the case being as they are, Her Majesty's Commissioners having before them the explanations we thought it our duty to lay before them, and not having received an answer to our communication, all we can ask of you is to adjourn this Meeting. We feel that ten days hence will be ample time for us to receive a definite reply from Her Majesty's Commissioners. I must point out, in justice to Her Majesty's Commissioners that during the Whitsuntide holidays "one man was gone to his farm and another to his merchandise," and so it was not altogether possible for them to assemble together. However, as far as that goes Her Majesty's Commissioners were not to blame [hear, hear]. At the same time I cannot help saying it is very unfortunate for the Society that we should be hung up in suspense [hear, hear], and I speak for myself and for my colleagues on the Council when I say that, should we be so unfortunate as not to be able to announce to you that a definite arrangement with Her Majesty's Commissioners has been made, we feel it our duty to place ourselves unreservedly in your hands, and ask you to take such action as may seem to you good in the matter [applause]. I really think I have little further to add except this, that if on the present occasion you will take my advice, given perhaps for the last time—and I assure you it is given after due deliberation and consultation with my colleagues—you will refrain from discussion on the position of the Society at this moment [hear, hear]. It could not further the objects we have in view to raise discussions which probably it would be difficult to answer at this moment, and I therefore invite you to pass, if you will permit me to say it, *sub silentio* the motion with which I shall conclude—that the Meeting be adjourned for ten days. There is one other word which I ought to say, and that is, our financial position has been greatly exaggerated. When we took office our debts—and I will not now enter particularly into figures—were very much larger than they are now. The amount of our debts has been steadily diminished under our exertions [hear, hear]; but I regret to tell you that very unpleasant action has been taken against our Society by persons from whom I think our Society ought to have looked for better treatment. Everyone here is aware that our funds have been falling off during the last two or three years, and everyone is equally aware we have been obliged to postpone the payment of the prizes granted in former years; of course I mean, as you can well understand, in last year. Well, certain gentlemen having made arrangements with their gardeners that part of the wages of those men should be whatever prizes they could make out of the pocket of the Royal Horticultural Society, and then, gardeners not having received these prizes, actions to recover them have been brought in the names of the gardeners, but in reality on behalf of gentlemen who ought, I think, show greater consideration for our Society [applause]. We have now been placed in the position either of having to pay these prizes or to be cited in the County Court for them. We choose the latter alternative for this reason—that although we have funds in our hands, and more than sufficient, to pay those prizes, yet our entire debts at this moment are rather larger than the funds at our present disposal. We think, therefore, to pay the gardeners under their threats of action before us would be, under the circumstances I have described, an objectionable form of preferential payment [cries of "hear"]. We, the Council, thought we ought not to pay at all under these circumstances—under threats, unless we could pay twenty shillings in the pound to all, which we can nearly do. But we thought it would be very unfair to our tradesmen if, because those gentlemen (for whom I have very little compassion) choose to press us in an indecent manner, we did not reserve the rights of those who have treated us with consideration. Our tradesmen have not pressed us, as they know very well we shall have ample funds from which everyone shall have his due. At the worst we do not owe half a year's income. Can anyone, or can most people say they are not half a year in advance of their income? [laughter]. I know a great many people who consider themselves extremely fortunate when they are no worse off than that [hear, and a laugh]. I merely mention this circumstance here because, between this and the time of our adjourned Meeting you may see chronicled proceedings in the County Court which may go against us, and in that case in order to carry out our principle we shall have to file a declaration of insolvency to protect our other creditors [oh! and no]. I hope, however, we shall in a short time be able to make such a statement of arrangement between the Commissioners, the Council, and our own Fellows outside as will place us in ample funds. But, ladies and gentlemen, it is well it should be borne in mind that of all those liabilities we are the inheritors, not the causers or the authors [hear]. Take my own case. It was not until after the vote which displaced the last Council that I became a member of the Society. After that vote I was asked to become a Fellow of the Society, and to do the best I could to place the Society in a better position than that in which it then stood. I acceded to that call, but I did not consider I should be made responsible for the state of things which then existed [hear, hear]. In common with other members of the Society I regretted that such a state of affairs should exist, but we did not consider ourselves responsible for it. I am prepared, and my friends of the Council around me are prepared, to enter fully and minutely into the circumstances of this Society. We are prepared to submit to you a scheme which we believe will land this Society in a prosperous position among the great societies of the country; but under the present circumstances you see my lips are sealed, and the lips of my colleagues are also sealed. I hope you will take our advice and not further discuss the position of this Society. We regret that many of you should have been brought from a distance to attend this Meeting, in order to aid, if you could, to get the Society through its difficulties. We are not responsible for this, and we hope you will be satisfied with our explanation [hear, hear].

Mr. H. S. Godson.—Have you any guarantee that Her Majesty's Commissioners will entertain your proposals between this and the expiration of ten days?

The Chairman.—None whatever.

Mr. A. Lindsay said he was of opinion that if the meeting consented to adjourn for ten days, it would be consistent with the duty the Council owed to the Society to state to the meeting what the nature of the proposals is which Her Majesty's Commissioners had under consideration [hear, hear]. The schemes brought before the Commissioners when he had a knowledge of these matters were such as neither that meeting nor any other meeting of the Fellows would entertain, and if the Council of the Royal Horticultural Society was in a position to say Her Majesty's Commissioners had accepted them, it would be for that meeting to negative them, which he had no doubt they would do. It was very important that this meeting, which was now asked to adjourn, should know exactly what the nature of the proposals before Her Majesty's Commissioners were [hear, hear]. More than that, it was highly important for the meeting, having the knowledge of the nature of the proposals, should be able to say whether they were such as they could or could not accept. So much for that part of the address of the Chairman, and he should, in the interests of the Society, ask the Fellows to weigh the matter carefully before they gave their vote upon it. With regard to a statement of the Chairman, he desired to say that as far as his knowledge went, it was not accurate to say that the debts of the Society were smaller than they had been when the present Council came into office. He (Mr. Lindsay) believed the debts of the Society were larger than they had been [cries of "no"]. Well, the debts were smaller in one sense, but if they were it was because the assets of the Society had been applied by the Council to the payments of the Society's debts [hear and "no"]. There was another point in his lordship's speech to which he should allude; it was that with respect to the prizes. As regarded those gentlemen who obtained the prizes, he felt bound to say that those of them to whom his lordship in the chair referred had very strong reasons to resent the way in which they had been reflected upon [hear and "no"]. He (Mr. Lindsay) never knew a gentleman who made the prizes his gardener obtained a portion of his wages; but there were a great many gentlemen who said to their gardeners, "If you choose to exhibit those things at your own cost, you may exhibit that which has been grown at my own cost and expenditure." Now acts of that description were very kind, and he did not think it right to say that gentlemen who acted in this way were acting in an ungentlemanly manner [hear, hear]. These very gardeners who had been spoken of by his lordship were out of pocket according to the extent to which they exhibited, and the result of the present position of affairs with respect to the Society was that the gardeners who had exhibited not only did not receive the bonus to which as prizewinners they were entitled, but, in

addition, were out of pocket money, which was their own *bonâ fide* property [hear, hear]. Under these circumstances he did not think it justifiable to say the actions in the County Court were being taken in reality by the gentlemen and only ostensibly by the gardeners. He sincerely hoped, however, they would succeed in their actions ["oh!" and hear]. The real reason why the funds of the Society had fallen off was by the neglect of provincial shows; but that, however, was not the fault of the Council, but of the general public. The Council might have held a show, and a good show, in the north this year. In conclusion, Mr. Lindsay said he was of opinion that the Chairman ought to state the grounds upon which an adjournment of the present Meeting was asked for.

Dr. KELLOCK observed that as regarded the gardeners and the loss of their prize money, Mr. Lindsay really knew nothing at all about the matter [laughter]. As to holding a meeting in the north, it was perfectly impossible to do so. There was no prize money to be got up there, and it would have cost the Society £2000 in money prizes to go to Wigan.

Mr. LINDSAY.—Have you any authority for that?

Dr. KELLOCK.—Oh yes, I have; you were on the Council at the time [laughter].

Mr. LINDSAY.—What is your authority?

Dr. KELLOCK.—It was Wigan, and it is unfair for any person to make such intemperate remarks. You only retired a few weeks ago from the Council, and if you had either good manners or good taste you would not to-day have spoken as you have ["oh, oh," and cheers].

Sir ALFRED SLADE said that no doubt anyone would have thought that the late Secretary of the Council would or could have spoken with some authority. With respect to that he (Sir Alfred Slade) had exactly the same sources of information that Mr. Lindsay had, and therefore, in the first place, he altogether objected to the principle laid down by Mr. Lindsay that the proposals of the Commissioners should either be disclosed to or discussed by that meeting [cheers]. He had understood that it was the expressed wish of the Annual General Meeting and of the adjourned Meeting of Fellows of the Royal Horticultural Society that all these negotiations between the Society and Her Majesty's Commissioners should be entrusted to the Council of the Society [cheers]. If Mr. Lindsay were on the Council now he would be the very last man to make the speech he had just delivered [hear, hear]. Mr. Lindsay said it was untrue the debts of the Society were less than what they were when he first sat at that board, but in the report presented that fact was stated, and that report was drafted by Mr. Lindsay himself [cheers and laughter]; so that when on the Council he was one who assured the Fellows that he laboured constantly to reduce the debts of the Society. He (Sir Alfred Slade) could assure the Meeting that he had as much confidence in the present Council —now that he sat amongst the Fellows—as he had when he sat at the Council Board [cheers].

Sir ALEXANDER GORDON said there was one observation he wished to make, and it was this, that it would be most unfair were they to declare their approval of any proposals or arrangement in that Meeting without consulting the five thousand Fellows of the Society. Verbal communications had been stated to be sufficient for adjourning the Meeting, but he took verbal communications to be most unsatisfactory and dangerous to act upon [hear, hear]. He should like to know whether the proposals made to Her Majesty's Commissioners were in writing, and whether they were to be taken into consideration at a future time?

Mr. GUEDALLA hoped the Council would withdraw the plea of insolvency [hear, hear], and pay the claims put forward in the County Court. It must be repugnant to every gentleman present—especially when it was considered their Society was a "Royal" one—to have a plea of insolvency entered on their behalf [hear, hear]. Why, he asked, should the Council file a plea of insolvency or a declaration of insolvency, as the Chairman told them would be the case? Let the Council pay every claim to the last farthing, and they would be supported by the Fellows.

The CHAIRMAN.—Let me call you to order for one moment. I did not say we were going to file a declaration of insolvency, but I said that if the cases went on we should rather do so than pay what we consider preferential claims.

Mr. GUEDALLA.—Well, you should pay what is due to the prizeholders [hear, hear]. Why should you be obliged to pay by compulsion? Pay away as far as you can, and when you have paid all you have got fall back upon us. I am sure it must be repugnant to every member of the Society to do such a thing as that proposed by the Chairman.

The CHAIRMAN.—I do hope the subject will not be pressed further. We are ready with our schemes. There are two of them in my hand, and I could read them to you and tell you everything that has taken place between ourselves and Her Majesty's Commissioners. We are perfectly ready to do all that, but we say it is not for the benefit of the Society that we should do so. Addressing to the Meeting questions like that which Sir Alexander Gordon put will simply place the Society in the very position we deprecate.

Sir ALEXANDER GORDON.—Well, I will only put this question, Whether the fact of asking if the proposals made by the Council of this Society to Her Majesty's Commissioners are in writing can place this Society in an embarrassing position?

The CHAIRMAN.—The whole correspondence with Her Majesty's Commissioners is in writing, and the only reason we do not bring that correspondence up is that we have not received an answer in writing from Her Majesty's Commissioners. We expect an answer from Her Majesty's Commissioners in ten days, and then we shall be glad to lay the whole matter before the Fellows.

Sir ALEXANDER GORDON.—And yet you may declare yourselves insolvent before the next ten days [hear, hear].

The CHAIRMAN.—We will as a matter of course defend the actions. What I said was put by way of illustration [oh!] What I did say was that it would be better to declare ourselves insolvent than to pay preferential claims [cries of "no."].

Mr. DOBREE (Treasurer) said if the Fellows really wanted to support the Society they ought to pay-up the amount of the subscriptions they owed. The amount was a considerable one ——

A FELLOW.—How much is it?

Mr. DOBREE.—£1240 is due from Fellows on this year ["oh, oh"]. Why do not these Fellows pay up their subscriptions? If they did so, they would materially assist us in carrying on the business of the Society [hear, hear]. We have done all we can do, but we cannot get on without money.

A FELLOW.—How much would put the Society in a good financial position?

Mr. DOBREE.—If we could find a sum of £5000 or £6000 dropped into our mouths we should be all right [laughter]. Supposing you suspended payment to-day, you have at your bankers about £2000. You owe for prizes £1400, and if I were to pay these rabid prizemen we should come to a dead stand. I will rather cut my hand off than sign a cheque to pay these prizes ["oh, oh"]. By paying them you give an undue preference to those men who won prizes at their masters' expense, because those very men who win the prizes win them at the cost of their masters' fuel, hothouses, &c. [no, and hear]. The thing is ridiculous. I have here one of the most ungentlemanly letters I ever read from a man named Wilkins about his gardener.

A FELLOW.—Read it.

Mr. DOBREE.—No, we will not read it [hear, hear]. Then to go on as to our financial position. We owe sundry accounts up to the 31st of December, and some up to the 25th of March, amounting to £1218 14*s.* 7*d.* We owe our Accountant fifty-two guineas, and we owe a Member of our Council, who put his hand in his pocket to pay for the die of the Lindley medal, between £60 and £70. That brings up our liabilities to a sum of £2703. Then we have current accounts amounting to say £200 or £300, making you owe, supposing we stopped to-day, rather more than £3000. Against that you have in your banker's hands £2000, and that we intend to protect; and if judgment is given against us in these County Court cases, the best thing we can do is to file a declaration of insolvency, and bring matters to a crisis [loud cries of "no," and a voice, "we will find funds," followed by interruption]. What are we to do if these men get judgments against us? Are we to pay all or some of them? [cries of "pay, pay," and order]. Well, you may take my place as Treasurer of the Society, but I will not sign a cheque to pay these prizes [uproar].

A FELLOW.—Somebody else must [cheers].

Mr. DOBREE.—You may do it, but I will not. As the Treasurer of the Society I am bound to protect the Society, and hence I will pay no preferential claims. If you insist on my doing it, you will have to find another Treasurer ["oh, oh"].

A FELLOW.—So we easily can [interruption].

Mr. DOBREE.—You owe about £3000, and against that you have £2000 in hand. That will pay a very handsome dividend [a laugh]. Your Fellows owe £1200, and we have a claim against Her Majesty's Commissioners for rent, &c., of between £900 and £1000. Still, all that wo'n't enable you to get along towards the end of the year. You will want a large sum to enable you to get along to the end of the year.

Dr. DENNY and Mr. GODSON rose to address the chair, but the latter gave way.

Dr. DENNY said their Treasurer had stated—whether rightly or wrongly he would not say—that they should declare themselves insolvent if judgment went against them. Well, they would be insolvent if judgment went against them previous to next meeting. Now he (Dr. Denny) asked what was to become of the Society's show after the statement made that day that the prizes would not be paid? [hear, hear]. Would they have any show whatever on the 2nd of June? Would it not be better for them to close their doors? ["no," "yes," and confusion]. Let them not turn swindlers and take 7*s.* 6*d.* for admission and yet have no show. Let them keep up the Society as honourable men, and even if the Society must fall, don't let them open their doors and charge 7*s.* 6*d.* for admission and have no show

whatever. This was a point they were not at all considering upon the question of adjournment. Let them pay their prizes [hear, hear], because if this went further, and they declined to pay their prizes, they would not have a single exhibited plant in their tent on Wednesday, the 2nd of June [hear, hear]. All he could say was that it was a very serious matter to take the public in.

The Chairman.—We do not propose to take the public in. On the last occasion we did not consider the show sufficiently good to warrant us in charging the price fixed, and we altered the admission to 1s.

Dr. Denny.—Very good so far, but what is to become of the Society, my lord?

The Chairman.—Perhaps you will find the money to put it straight.

Dr. Denny.—Had we not better wind it up?

The Chairman.—I say, wait for ten days, and for God's sake wind it up then.

Mr. Denny.—You actually propose to do it before then.

Mr. Andrew Murray reminded the Meeting that the Society was not altogether insolvent, because they had a large amount of stock at Chiswick, and various matters at Kensington, which would bring in considerable sums of money. They had a large number of subscribers and Fellows, and these prizemen, if they were asked, would be only too glad to postpone pressing their claims.

Mr. H. S. Godson said that one and twenty years ago they were in a position similar to their present one, and what did they do? They did not listen to the "cuckoo cry" uttered not only by the present but by the former Council. Why did not the Council and the Fellows put their hands in their pockets? He (Mr. Godson) was ready to put down £20, and give £5 towards the prizes [hear, hear]. Let one hundred others say the same, and the whole business could be easily settled [cheers]. If the present Council or the Royal Commissioners could not give their time to the business of the Society let a Committee of Investigation be appointed the same as there was twenty years ago. At the time he referred to they paid everybody. Let them now pay as honest men. Let every man put down his name for so much. What had they been doing? They had been inducing people to come there to South Kensington to exhibit flowers and plants for the sake of getting prizes. Let them be honest at all events, even if they spent the coats off their backs [cheers and laughter]. Let a Committee of Investigation be appointed, and he should prove that Her Majesty's Commissioners owed the Fellows £9000. The question now was, Pay or not pay.

Mr. Andrew Murray seconded the motion proposed by the Chairman, that the Meeting be adjourned for ten days.

The Chairman then put the motion.

Mr. W. Bull said he sympathised very much with the Council.

The Chairman.—I have put the question of adjournment. Let it be decided, and the Meeting will hear you afterwards.

The motion was then put and carried, with a few dissentients.

Mr. W. Bull said he desired to state that he heartily sympathised with the Council, but then their great Show took place next week and the meeting had heard nothing of what was being done to carry out that Show. There would be no prizes, and he thought there ought really to be some scheme laid before them by which the prize money could be got [hear, hear]. He was surprised to find that the Council was taking no action with those who were the friends of the Society. The prize money would not amount to more than £600 or £700. Therefore, let a number of the Fellows subscribe to pay the prize money the day after the Show. It was, he thought, a most humiliating position for the Society to be placed in.

The Chairman.—Mr. Bull's proposition will be considered.

A vote of thanks was given to the Chairman, and then the Meeting stood adjourned to Friday the 4th of June.

[It was understood that Mr. W. Bull stated at the end of his speech that he should put down £100 towards the forthcoming prize-list. In the noise and confusion caused by the Meeting breaking-up as soon as Mr. Bull began to address it, it was impossible to catch what he said.]

ROYAL BOTANIC SOCIETY.

The Exhibition at Regent's Park yesterday must, both as to quality of plants and arrangement, be pronounced very superior. On entering the marquee the bold masses of Azaleas, Roses, and Pelargoniums were strikingly effective. Time only permits a hasty glance, minus the awards, which were not made when we left the tent.

In the nurserymen's class for twelve stove and greenhouse plants in flower Mr. B. S. Williams and Messrs. Jackson & Sons staged admirable collections. Mr. Morse, Epsom, also sent good plants. In the corresponding class for amateurs—ten plants—handsome groups were contributed by Mr. Ward, gardener to F. J. Wilkins, Esq; Mr. Chapman, gardener to J. Spode, Esq.; Mr. Toms, gardener to H. Wettenhall, Esq.; and Mr. Carr, gardener to J. L. Hinds, Esq. In these groups the Ixoras, Ericas, and Azaleas were very fine. For six stove and greenhouse plants equally good specimens were exhibited, Messrs. Jackson & Sons, Mr. B. S. Williams, and Mr. Morse being prominent amongst nurserymen; and Mr. Ward, Mr. Chapman, gardener to J. Spode, Esq., Hawkyard Park, and Mr. Toms being to the front in the amateurs' class. Ixoras, Aphelexes, and Clerodendrons were prominent in the collections.

The Azalea classes were a show in themselves, so admirably were the plants bloomed and exhibited. Amongst nurserymen, for twelve plants in 12-inch pots, the examples from Mr. Turner and Messrs. Ivery & Son were well-finished densely-bloomed plants. For six plants unlimited as to size of pot, immense specimens were staged by Mr. Ward, Mr. Child, Mr. Wheeler, and nice pyramids from Mr. Ratty. Amongst the nurserymen's "giants," noticeable were those of Mr. Williams, Messrs. Lane and Son, and very perfect smaller plants from Messrs. Ivery and Son.

Roses were an imposing feature of the Exhibition. In the classes for six and nine plants Messrs. Paul & Son, Cheshunt, Messrs. Lane & Son, and Mr. Turner staged splendid examples of cultural skill, while an attractive bank of decorative plants in the class for twenty in 8-inch pots was contributed by the same renowned growers, those from Cheshunt being the best. Messrs. Lane & Son sent excellent boxes of cut blooms, La France being in splendid form.

Heaths were very good. For six plants (nurserymen) Messrs. Jackson & Sons, Kingston, and Mr. Morse, Epsom, competed. In the class for twelve the same growers sent smaller but well-grown plants. In the amateurs' classes Mr. Ward and Mr. Wheeler had splendidly-bloomed globular specimens.

Orchids were exhibited by Mr. Williams, who had healthy handsome plants of Cattleyas, Vandas, and Cypripediums. Messrs. Jackson & Son and Mr. Morse also contributed highly interesting groups. Amateurs were represented by Messrs. Ward, Ritchie, and Child, who had creditable specimens. Exotic Ferns came from Mr. Wheeler, Mr. Ritchie, Mr. Carr, and Mr. Williams, and good collections of fine-foliaged plants from Mr. Legge, gardener to S. Ralli, Esq.; Mr. Carr, gardener to L. J. Hinds, Esq.; Mr. Clark, gardener to A. Shuter, Esq.; and Mr. Wheeler.

Pelargoniums were excellently exhibited by Mr. Ward, Messrs. Dobson & Son, and Mr. James, Mr. Ward's plants averaging 5 feet in diameter. Calceolarias from Messrs. Dobson & Son and Mr. James were sturdy well-bloomed plants. Mr. R. Parker, Tooting, and Mr. Ward exhibited beautiful groups of hardy herbaceous plants, and Messrs. Jackman & Son a fine collection of Clematises.

In the classes for new plants Messrs. Ivery & Son exhibited Azaleas; Mr. Bull Pelargonium Beauty of Oxton, very telling, also a bright Aucuba, Luteo picta, a quaint Pilocerus, a bright Blandfordia, &c. Messrs. Jackman & Son had two handsome Clematises, Alba magna and Mrs. Hope; Mr. George Ivy-leaved Pelargoniums; Mr. Foster and Mr. Turner superior Show and Fancy Pelargoniums, the last-named exhibitor also showing a new white dwarf Lobelia, Duchess of Edinburgh. Mr. Braid staged his Pelargonium Duchess of Edinburgh, which is exceedingly free and floriferous. Messrs. James Veitch & Sons, Mr. B. S. Williams, and Messrs. E. G. Henderson & Sons also sent valuable collections of plants of considerable interest and beauty, and Mr. Croucher staged a novel group of Agaves.

CHAPTERS on INSECTS for GARDENERS.—No. 1.

Many persons, who not only pride themselves on being well educated but who really are so, would be much perplexed if required to answer off-hand this question, What is an insect? As the story goes, at some party where the definition was asked for, and a variety of replies, none deemed satisfactory, had been given, a Scotchman with grave face announced that he would end the difficulty, and having secured general attention remarked, "Weel! an insect is just an insect, and that's all about it!" which was a cutting of the Gordian knot. And some of us will remember the cut in *Punch*, representing a gentleman standing on a railway platform in some perplexity with a tortoise in his hand and a lot of luggage about him, and an obliging porter informs him when he asks what he will have, to pay, that "rabbits and cats are dogs, but you won't have to pay anything for that, because it's an insect!" And many other creatures as far remote from insects as are tortoises are popularly reputed to belong to that class because of their mode of life.

All creeping crawling things are insects in the eyes of some people; I have even noticed the name applied to small gliding mammals, such as the field mouse. Those with a little more idea of the right mode of classifying animals may perhaps derive some light through the circumstance that insects have more legs than quadrupeds, birds, or reptiles; but if they would

answer, "An insect is a creature with six or more legs," they are checked by the recollection of various grubs and maggots that are footless. I have heard it given as a broad definition of an insect that it is an animal that can fly, walk, or run, which is obviously inapplicable to all insects in their preparatory stages, and only suiting a proportion in the perfect or imago condition. Mr. Wood alludes to a section of the community in whose minds there rests a belief that insects are only skin and squash, but even these would scarcely give this simple formula forth as a definition. Then as to size and shape—these are no standards, since some insects are larger than certain quadrupeds or birds; and as to shape, there is an infinite variety of this noticeable in the insect world. But the word just used needs only to be broken in two, and we at once have a help to the right understanding of the nature of an insect. The body is divided into parts, sections, or segments, more or less noticeable in different species and individuals, yet always existent, and furnishing a most reliable distinction, since no such formation occurs in the higher animals. I point this out as immediately connected with the familiar English name, but there are other distinctions sufficiently obvious, and easily remembered when once pointed out, to which I shall have to make reference presently.

If I were asked, "What classes of men are by their employment brought into most frequent contact with the insect races?" I should have no difficulty in answering, Horticulturists and agriculturists; a necessary consequence from the fact that the great majority of insects are to be found living upon or closely associated with vegetable growths. Yet, speaking generally, it is not amongst these that we find a large amount of knowledge with regard to insect appearances and insect habits. If there is a familiarity that breeds contempt, as a proverb assures us there is, we may discover also a familiarity that produces both dislike and ignorance, contradictory as that may appear. Yet in saying this, and speaking more particularly of horticulture, which concerns us here, my observations are applicable rather to the time that has past than to the present moment, for amongst amateurs and professional gardeners we now perceive a growing inclination to acquire insect lore. With some, possibly with most, the moving cause is the recognition of the truth that it is highly advantageous to gain at least an outline knowledge of the insects that belong to the garden, orchard, or plantation, viewed as friends, foes, or neutrals in their relation to the work of the horticulturist. Then I am also glad to record that an increasing number of entomologists is being drawn from the ranks of gardeners, some becoming much interested in the curious structures and the remarkable habits of these creatures, long unjustly deemed to be nothing better than nature's nuisances. And the day may come when such facilities for acquiring a knowledge of insects as entomological classes, or series of lectures specially suitable to gardeners and well illustrated with living or dead specimens, may be common in London and other towns.

It is interesting to become acquainted with the histories of particular insects, and in this Journal from various sources, and occasionally of late years from the pen of the present author, numerous facts have been published which it may be presumed are not without their value to gardeners. But of course the references to insects thus given from time to time cannot be supposed to help greatly towards a methodical knowledge of insects as a class of living things, though they bring out prominently individual species. I have recently observed that, however well such life-histories may be sketched, something more is wanting to bring up the gardener's knowledge of insects to the proper standpoint. A man may read, and even ponder carefully, much that is written upon insects, and yet have very hazy notions about their grouping or classification. Is this an indifferent matter? Assuredly not. Few are so ignorant as not to perceive that a beetle and a moth are decidedly unlike each other, and that a grasshopper and a blow-fly are not next-of-kin, but they may not go much farther. Whether we have as many kinds of beetles as of moths, or in what respects the grasshopper's life is different from that of the blow-fly, about these and a host of other particulars they are in the dark. Now, it could be demonstrated that an acquaintance with insects as distinguished into orders, families, genera, and species, is helpful towards mental improvement; but it is more to our purpose to assert, as we may, that to the horticulturist a knowledge of some of the broad distinctions is highly helpful. As a general rule the habits of groups show a certain identity throughout, and with an insight into the general history of any one group of insects we are the better prepared to understand a species belonging to that group. In these pages I shall suppose myself accompanied by an intelligent horticulturist who wishes to have, in a style not too scientific, an outline sketch of the insect world so far as it concerns us in these islands; and if there should be some who think I am repeating what is, or what ought to be, already known to the reader, I would remind these that it is as well to obviate possible difficulties at the outset.

Let anyone who is by no means a naturalist pick up the next frog he comes upon, and take a big caterpillar off the handiest bush. As he looks at the somewhat incongruous pair he sees differences, it is true, yet he is most likely tempted to consider that they are in much closer alliance than, say, a quadruped and a bird. But herein he is wrong, and stress must be laid on the grand distinction between vertebrates and invertebrates. In the vertebrates, running down from man to reptiles and fishes, there is always found a backbone—the spinal column. The skull may be wanting as in fishes, or the limbs and ribs as in various reptiles, but in each class of the vertebrates there is an internal skeleton on which the framework of the body is built up. An old writer, who took upon himself to unravel the mysteries of Scripture natural history, saw a fancied distinction between the "creeping things" of Genesis and flying insects. By the former term, he argued, only such insects as creep, walk, or leap could be intended. Winged insects must be placed under the category of "fowls of the air." But from the mere possession of wings nothing can be proved as to similarity, for though birds and some insects have these organs of flight, they are farther apart in reality than insects and molluscs or worms, which are totally incapable of aërial movements.

Insects, then, like all invertebrate animals, have no backbone, and of necessity it follows that there is no central brain—no organ to which the sensibilities, resident in the various parts of the body, send "telegraphic communications," if one may so speak. All the older naturalists denied insects both a nervous and a circulatory system, but therein they were probably wrong. In the latter circumstance they came to a hasty conclusion, because on dissection they could not detect any heart nor an obvious motion of fluids throughout the body. Now our best authorities support the theory that a long muscular canal extending from the head to the tail, and supplied with a series of valves, acts as a compound heart; from it are distributed numerous minute ramifications, and through these channels, as is supposed, the dorsal vessel sends through the body, and receives again, a vital fluid, which we might call blood, as it fulfils the same end. Mr. Newman, indeed, suggests that when one caterpillar bites another, as happens occasionally among the species that are inclined to be quarrelsome, the flow of this greenish substance proves an incentive to rage, which, were it true, would show an analogy to the recognised effects of a blow drawing blood in some creatures of nobler race. Then, as to nerves, "thereby hangs a tail;" connected with these there lies a much-vexed and as yet unsolved question —How far insects have the sensation of pain? I am not going to spill any ink in the controversy here, though I have been in the battle-field in days gone by. Suffice it to say that insects have a succession of nerve-centres or ganglions, which are arranged along the body and limbs, and which seem to be independent of each other. Seem! but there is the puzzle. If they were so entirely the head of an insect might want to go one way, the body in another direction, and the legs in another; but somehow all the movements are brought into harmony. Still, it is an odd fact that, as has been often proved, you may cut an insect about strangely without causing its immediate death. Then again, as to breathing, there we have the tube arrangement again. On each side of the body of an insect an air vessel or passage is situate, with several openings, called spiracles or breathing pores, communicating with the external air. The stoppage of these is death, and hence the speed with which a wasp or bee may be laid prostrate by just touching the abdomen with a feather dipped in oil.

But as to general outline: If we take for examination a fly, which is at the lower end of the class, or a beetle, which stands at the summit; though the one has two wings merely, and the other two wings and two elytra or wing-cases, they have each six legs, the almost universal number among perfect insects; and the body is divisible into the three portions, called the head, thorax, and abdomen. In all insects the head is hard, aptly described by one writer as a kind of box, formed of a single piece, and bears the antennæ in front—peculiar organs, which in different species show so much variety. They are occasion-

ally called "feelers;" but this name properly applies to smaller organs called "palpi." If we want another name for antennæ we may call them "horns." The head is also distinguished by compound or facetted eyes, which give an insect a facility of seeing in all directions without moving the head or rolling the eyes; that, in fact, is to insects an impossible performance. Other circumstances distinguishing insects must be noticed subsequently.—C.

CUCUMBERS—ROYAL HORTICULTURAL SOCIETY.

Steadily and progressively advancing is horticulture to a high standard of excellence, both in the raising of improved varieties and in cultural practice. In no department of gardening has the advance been so decided as in Cucumbers. Many excellent varieties have from time to time been raised as improvements upon existing kinds. Their originality and quality have in many, and I may say most, instances been vouched for by the granting of certificates by the Royal Horticultural Society, decided by the outward appearance of the fruit. Outward evidences of quality are, however, seldom deceptive, so that no doubt need be entertained as to certificated subjects being all they are put forward to be in quality. There are, however, other equally momentous desirabilities, especially to the cultivator—viz., constitution and free-bearing. These latter cultural qualities have been ably carried out at the Society's experimental garden with many subjects, the two combined being the best guarantee the public can have of the sterling merit of the subject certificated.

Such a Society cannot but be of the highest value alike to raisers and horticulturists generally, as well as to the public at large, for if not directly they must indirectly be interested in all improvements of quality and quantity. In these days the one is of no use without the other, and it is just this which has brought the Society into such disfavour with horticulturists. All along the line the cry ascends, What is the good of the Society to gardeners? Its subscriptions are so high as to exclude the vast majority, whilst the advantages of membership are so indefinite as to preclude those who could, and unquestionably would, join hand and head with the Society. The whole life-history of the Society, or at least of late years, has been to drive from its councils and participation in its work practical horticulturists. As representing horticulture it, so far as gardeners are concerned, has no claim, for from the time that it took upon itself to stop criticism by rejecting the "Gardeners' Magazine" of London, because it contained some "offensive" expressions, which pointed out the inutility of the papers of its then President to practical gardeners. Various efforts, feeble though they were, have from time to time been made to ameliorate the condition and bring into closer connection with the Society the workers of the horticultural hive—notably the admission of young gardeners into the Chiswick garden for a course of training preparatory to an examination with a view to a certificate, and the admission of local societies into union, and the holding of provincial meetings. Notwithstanding these advances, the tenor of the Society has been to horticulturists, and to the craft in particular, a heave only of the cold shoulder. I write not in disparagement, nor with a desire of wounding anyone's susceptibilities, but in a spirit which not unmoved by past wrongs is fully alive to the importance of the Society as a centre of horticultural encouragement, enlightenment, taste, and in furtherance of the best interests of horticulture throughout the empire, home and colonial.

It is of no use dwelling on the palmy days of Chiswick—they are gone; but there is no good in keeping even the Chiswick establishment as an experimental garden, and fritting away its resources as such as a furnishing ground for the South Kensington garden. It is simply means put to anything but a horticultural employment, for the South Kensington gardens have not any pretension to the display of either arboriculture or floriculture in their highest forms. There is no disputing their desirability as a lung to wealthy persons who have country residences, and who miss during the London season the garden sweets, and therefore wish to have a spot near at hand to which they can resort for promenade amid bright flowers, inhaling balmy breezes and discussing sweet music. Very grand, no doubt, but what is there in it all of horticultural taste and refinement? Nothing that I can see at South Kensington would for a moment lead a horticulturist to take interest in seeking its continuance, to say nothing of the weightier consideration to him of advancing the art to which his every idea is wedded. The only way in which it can or has advanced horticulture, is by its appropriateness for the holding of the Society's meetings and exhibitions. This, if I remember rightly, was the primary object in the acquisition of the Kensington Garden. Its object has been lost sight of, and horticultural Fellows can see only their subscriptions expended upon subjects foreign to the exalting of that they have at heart—the advancement of horticulture.

Now, the pointing-out of a nuisance without suggesting a remedy is said, instead of lessening the evil, to only render it more offensive, and as the estrangement seems to be of taste and the difficulty one of debt, it is only fair that those causing the one should make up the other. Surely those who have had the garden as a promenade can well afford to meet any claims for expenses incurred in view of the advancement of their particular ideas and for their especial gratification.

In future it is to be hoped the claim of gardeners upon the Society will not be ignored, for what society professedly horticultural can exist which is not representative of the encouragers as well as the workers at the art? Every other body but this admits the claims of workers to a representative interest in matters which concern them equally with the promoters: hence boards of conciliation and arbitration are just what the Society at present needs to set things right. The days are waning when the labour by which the exhibitions are upheld will not be maintained by a monetary consideration. The labour which brings to the exhibition-table the perfection of horticultural products has a right to a representation of its interests in an intellectual manner, which is an admitted power in every industry; and any society professing to advance any art which does not admit to a fair representation in its counsels and management of affairs of all parties interested therein comes to nought, failing financially as this has done.

The claims of gardeners have been made before, and I do not see why they should not be admitted to fellowship as justifiably as those who are more favourably circumstanced as regards this world's goods, and on that account can afford to pay a higher subscription. A guinea gardener-fellowship as proposed by, I think, Mr. Wilson and seconded by Mr. Douglas, is a fair proposition, and would give the labour side of horticulture a reasonable representation. Advantages they might have in proportion to the value of their subscription, this to be settled by a committee composed of an equal number of the several rates of subscribers. But there could not be a fair representation unless voting by proxy were established. It would be most inconvenient to attend its meetings personally, to say nothing of needless expense, when an opinion could be recorded equally well before as after a subject was verbally discussed.

The subject has cropped out from having the pleasure to treat of a Cucumber which bears the Douglas motto, "Tender and True." It is, indeed, a grand sort, of free growth and hardy constitution, a short neck and nose, of even thickness, very regular outline, carrying a fine bloom, the flower well borne. It is very free-bearing, and commences to do so in its early stages—earlier than others, swells kindly and quickly; the flesh of a good green colour, crisp, and excellent in flavour. It is superior in length to Blue Gown, being a long kind—30 inches long when well grown, and good alike for exhibition or table use. Unquestionably this is the finest Cucumber in cultivation, and its merits cannot be too extensively known, which must be my excuse for so early in the season alluding to it. Duke of Edinburgh (Munro's) is also a very free-bearing sort of the Sion House class, with very short neck and nose, and about a foot in length, very regular in outline, and every way good. The flesh is crisp and good-flavoured, and it appears to have a good hardy constitution. What Tender and True is among the large kinds this is in the smaller, decided improvements upon older varieties, Tender and True being superior to all other, every purpose considered.—G. Abbey.

RABBIT-PROOF PLANTS.

In accordance with your request to your readers on page 378, I will in a few words relate my experience of plants rabbit and hare-proof or the reverse, founded on several years' observation in a place where rabbits and hares are more destructive than I have ever observed them elsewhere.

Rhododendrons are the only evergreens never touched by them. The common Yew, Privet (especially the oval-leaved sort), common and Portugal Laurels, Aucubas, Sweet Bays, Escal-

lonias, Thujas, Gorse, Laurustinus, Evergreen Oaks, and coarse Hollies are more or less eaten. Amongst deciduous trees and shrubs I have only observed Birch, Blackthorn, Elder, Sea Buckthorn, Laburnums, and Dogwood entirely escape the ravages of ground game, though Elm, Alder, and Horse Chestnut are seldom attacked except in very severe weather. Of the Fir tribe Pinus Laricio and P. insignis are rarely if ever touched. Pinaster, Scotch and Silver Firs are more or less eaten, and the Austrian Pine worse than any other sort. Fuchsia Riccartoni, Weigelas, Deutzias, Willows, and Hydrangeas are often eaten.

Hares are more generally destructive than rabbits; for instance, Aucubas, Portugal Laurels, Bays, and other plants are, I believe, seldom if at all eaten by rabbits, but are often destroyed by hares. It is easy enough in many cases to tell whether the mischief is done by rabbits or hares.—J. Ellam, *Bodorgan*.

OUR BORDER FLOWERS—TRILLIUMS.

It would in all probability be a difficult matter to find a family of plants less known than are the Trilliums, for though introduced a great many years ago we seldom see them in cultivation. On one occasion, being desirous of possessing some of them, application was made, but the answer received was, "We only have the store plant, and should not like to part with it." It was quite right to keep the stock, but why should one of Nature's choicest gems be so far in the shade? Is it that they are not known, or that they are not cared for, or both? Perhaps the truth is that they are little known and less cared for or understood; if so, no wonder that we so seldom meet with them in cultivation. There is sometimes less success in thought than in action. Thinking that a plant or subject is difficult causes us to pass by what we ought to attempt. Some thirty years ago, when looking over Mr. Backhouse's nursery at York, I noticed a plant standing on a path evidently intended to benefit by the genial atmosphere of a lovely April morning. The thought arose, What have we here? The label denoted Trillium grandiflorum. I shall never forget that plant. The Trilliums are a very singular as well as a very beautiful race of plants, and they certainly should be extensively cultivated.

It is said they are increased by seed, but to the present time I have not been fortunate enough to secure seed. They may be increased by division, but it almost unnerves one to attempt the operation; but as the old adage has it, "Nothing venture nothing have." They may be grown in pots as alpines, but should have thorough drainage, and be kept plunged where they can enjoy the sunlight and be protected from the wind. They will succeed on a sheltered part of the rockery, but it is well to protect the crowns in the winter. Much time, care, and patience is required to work up a stock, and when once well established let well alone and do not needlessly disturb them. They are quite at home in the cold fernery under glass.

After thorough drainage has been secured, a compost two parts sandy peat, one of good fibrous loam, a little leaf mould, a good sprinkling of silver sand, and charcoal dust with knobs of freestone, well mixed together, will afford them a good medium for their roots. White and red are the prevailing colour of the flowers, and in a mixed group they produce a grand effect. I have never seen them fully exposed in the ordinary border. If taken in hand they would prove an addition to the early spring exhibition.

Trillium grandiflorum is most common, and one of the best. T. atropurpureum I have not yet seen. T. sessile has much the same appearance as grandiflorum. T. pumilum is of dwarf habit, and desirable for contrast of colour. There are other species, but they are only to be seen in very choice collections. They ought to be taken in hand by some clever hybridist, and let us have a more sturdy race, for they ought to be seen in every garden where choice plants are in request. —Veritas.

[Trillium grandiflorum staged by Messrs. Rollisson & Sons at South Kensington on the 12th inst. was one of the most attractive plants in the Exhibition.—Eds.]

PACKING GRAPES, NOT TO BE EXHIBITED.

Take a garden basket of the ordinary shape, with sloping not straight sides, line it with cotton wool bottom and sides, and pack the Grapes stalk upwards as tight as they will go; tie tape to distinguish the stalk of the last bunch put in, as it is the first that should come out, and put paper over the basket. No guard or porter can turn it on its side or lift it otherwise than by the handle, and the said handle prevents anything being put on the top of it.—R. T. F.

THE DORONICUMS.

Where hardy, free-growing, bright yellow flowers are required in the month of May, no genus will supply them better than this. For a bold mass of yellow even the proverbial "sea of Daffodils" cannot surpass the glittering effect of a wavy expanse of Doronicums. The plants are very old, very hardy, and of very easy culture. They are not at all particular as to soil, and will grow both under trees and in exposed situations. Before the advent of spring gardening they were regarded as of little value, and the clumps were left to struggle for existence in the cottagers' plots and shrubbery borders where they happened to be situated. They are now considered worthy of better care, and have even won a place of being exhibited in pots at the Royal Horticultural Society's Gardens. For bold masses of colour, for distant effect particularly, they are admirably adapted. Their collective effect is greater than their individual beauty, and hence they show to advantage in large clumps and broad lines.

They are composite flowers belonging to the natural order Asteraceæ, and are increased by root-division. They may be removed safely with balls of earth as soon as they have done blooming, and can be replanted in their flowering quarters in autumn or very early in the spring. D. Columnæ grows about 2 feet high, and D. austriacum, D. cordifolium, and D. caucasicum about a foot high. These are the best, and flower in May. D. dentatum and D. scorpoides are also early bloomers. D. altaicum is a white summer-flowering variety, but the spring-bloomers are the most useful and recommendable. The Doronicums are the brightest hardy spring-flowering plants we possess, and being in perfection at the same period as Aubrietias, Arabis, Hepaticas, Polyanthuses, &c., enhances their usefulness.

These plants are likely to be more extensively used in the future than they have been in the past; and those who are anxious of keeping abreast of the times, and who covet a share in the "latest fashion" of garden decoration, would do well to add Doronicums to their list, or if they already possess plants to increase their stock by dividing the roots. When the plants have done blooming, north or partially-shaded borders are good positions for increasing and preparing these plants in summer, from whence they can be transferred to their blooming sites when the beds or borders are cleared of their summer occupants in the autumn. Patches or lines in shrubbery borders if left undisturbed will continue to bloom freely for many years. For such positions these hardy spring flowers are very suitable, and should be planted freely wherever bright flowers in May are coveted.—W.

HELLEBORUS FŒTIDUS.

It is exceedingly rare that Mr. Robson either overcolours or overestimates a plant or subject. Probably on no writer of the day is more reliance placed than on the veteran contributor. He is generally regarded as a "safe" man, a compliment which all writers would do well to win by an expression of plain practice, sober experience, and correct judgment. Yet I am inclined to think he overestimates (see page 344) this plant as a hardy ornamental early spring flower. I do not mean to assert that it is not what he describes it to be—viz., hardy, and in general appearance ornamental. It is indeed extremely hardy, and its foliage and habit of growth is agreeable, but the flowers—of which too much may be expected by those not knowing the plant—are dingy and devoid of any effect which is usually looked for in spring plants. I have grown it as a spring bedding plant, but my employer told me not to grow it again. It is interesting but too dull—sombre rather than cheerful—therefore not likely to become popular.—A Town Gardener.

Wistaria consequana.—In the gardens here, Brynkinalt, Chirk, North Wales, the seat of the Right Hon. Lord A. E. Hill Trevor, M.P., there is at present (May 21) in full flower, and has been so for the last three weeks, two plants of Wistaria consequana (sinensis) which for size and profusion of bloom I have not seen equalled. Such cover a space of wall 56 by 13 feet, and carry, roughly calculated—as it is almost impossible to do so accurately—about 2200 racemes of their lavender-

coloured flowers, many of the racemes being over 12 inches in length. From some of the spurs depend fifty racemes. I should like to hear if many such plants are in existence. I may add that these plants would have covered many more feet of wall, but are prevented doing so by vineries on either side.—J. A., *Gardener*.

THE GALEGAS.

Now that hardy flowers are having a reasonable share of attention bestowed on them, and are again deemed worthy of a place in our gardens, it is not inopportune to note the merits of this useful genus of border plants.

The Galegas are very old and very hardy Leguminous herbaceous perennials, and are known by the popular term of "Goat's Rue," in reference to an old idea that the herbage was superior for milch cows and goats. About half a dozen species are cultivated, the best being G. officinalis and its white variety alba, and G. orientalis.

G. officinalis is one of our oldest border plants, having been introduced from Spain more than three hundred years ago. It is only to be found where collections of hardy plants are cherished, or where it has taken care of itself in some shrubbery border where it has been tolerated to continue. Little more than a toleration to exist it does not require, for it has a most accommodating nature, and will grow and flower year by year with as little attention as most plants. And yet it is not only agreeable but decidedly ornamental; indeed, it is one of the best of tall-growing back plants for the herbaceous border. Its sprays are ever in request for cutting for bouquets, possessing an airy lightness and an Acacia-like foliage, which group to advantage without flatness and formality. Besides, the flowers are of a colour which is pleasing and always welcome, being of a lively light blue. They are produced with great freedom from the axils of the leaves, and the long spikes are very effective. The plants commence flowering in July, and continue until the autumn—indeed, until the growth has ceased, for so long as the plant grows it flowers.

Fig. 98.—Galega officinalis.

The height of the plants depend on the nature of the soil. In rich ground they attain a height of 3 to 4 feet, but in poor soil not more than half that height, but in each case they flower profusely; moreover, the plants will bear cutting and pinching, and are easily kept within required bounds. This and the white variety are two very useful border flowers where hardy plants of moderately robust growth are in request. They will flourish in any ordinary garden soil, and only require to be staked and neatly tied, and to be pinched when necessary to keep them in order. They will flourish on the same site for many years, providing their fleshy roots are not ruthlessly mutilated in winter digging.

They are increased by root-division during the spring and early summer months, the plant, in fact, being so easy of growth as to bear removal almost at any time when not in flower. These are free-growing yet compact and pleasing border plants, and worthy of cultivation for their ornamental appearance, and for their usefulness in affording a supply of flowers for cutting.

G. orientalis and the rest of the species are more weedy and spreading than the preceding, still where a love of hardy flowers prevail they are desirable as affording variety. But for general usefulness the species now figured and its white variety are the most worthy.—W.

CONIFERS IN EXPOSED SITUATIONS.—No. 2.

Crimean Silver Fir (Picea Nordmanniana). This Conifer, handsome as it is, does not stand the wind well, and becomes depressed in habit, the perpendicular growth being slow and weak. The leaves are somewhat browned in winter, and the last year's growths have a sickly yellow hue in spring. In moderately sheltered positions it does better and is fine, its bright green foliage contrasting well with the dark glaucous shading of P. nobilis.

Noble Silver Fir (P. nobilis). This is of free growth, not suffering from wind and exposure, and in my estimation is the finest of all Conifers; its dense dark green foliage, silvery or glaucous beneath, having an extremely beautiful appearance.

Spanish Silver Fir (P. pinsapo) is a particularly handsome tree, its growth being peculiar. The numerous branches are produced in whorls, every leaf and branch being arranged with perfect symmetry, and is highly ornamental. It is not injured in the least by wind, but grows vigorously, forming a specimen of great beauty.

Great Californian Silver Fir (P. grandis). Of this there are evidently two varieties perfectly distinct, and of different degrees of hardiness. One variety is somewhat sparse of leaves, which are rather long and slightly curved or curled. This grows but moderately, and is so cut by a hard winter as to lose some of its leaves in spring. It is very handsome notwithstanding, but is not so hardy nor so free in growth as the other, which is more dense in foliage, of deeper green, and grows 2 to 3 feet in a season, truly a beautiful quick-growing kind; it is occasionally slightly browned by cutting winds.

The Common Silver (P. pectinata), and Balm of Gilead (P. balsamea), do not do well except in sheltered positions, and there they attain noble proportions. In exposed positions the growths are browned, which spoils their appearance.

Siberian (also Swiss) Pine (Pinus Cembra). The upright conical growth and dense glaucous shading of the leaves, which are deep green on the upper surface, and from its habit taking up little room, renders it one of the most desirable Pines for a small pleasure ground, especially where something evergreen and taller than shrubs is required. It is also one of the best for planting in the neighbourhood of towns. In very exposed

positions its leaves are slightly browned in winter, but with only moderate shelter it does well, and is very handsome.

Lofty Bhotan Pine (P. excelsa) is rapid-growing and spreading, having a spread at the base of the branches often more than twice the height of the trees. To say that it is beautiful is not adequately expressing its value, for its distinctness, and bluish green drooping leaves and bright green of its wood render it peculiarly attractive. Its branches lying flat upon the ground render it a favourite resort of ground game, and pheasants make choice of it for roosting and nesting; it stands next to the Corsican Pine for escaping the ravages of hares and rabbits, which, except when fresh planted, do not eat it. Except in a very exposed position its leaves are not browned in winter, and in a moderately sheltered site are not at all injured. For rapidity of growth it is about equal with the Corsican Pine.

Weymouth Pine (P. Strobus) is cut by both the east and west winds. In an exposed position it soon languishes and dies. In a moderately sheltered situation it grows about half as well as P. excelsa, which is twice as good.

Pea-fruited Japan Cypress (Retinospora pisifera) is not unlike a plumose form of Lawson's Cypress, but with a brown or pale chocolate tint. It stands wind tolerably well, and grows moderately, and is very desirable for partially sheltered positions.

Maiden-hair Tree (Salisburia adiantifolia) grows moderately, and neither the wood nor the young leaf-growths are injured by cold.

Californian Redwood (Sequoia sempervirens) has all its growths browned and killed by a severe winter, except a slight portion of the ripe wood, from which it puts out fresh shoots annually. It has been recommended as a screen or hedge plant, and in sheltered positions it may be useful for that purpose, bearing cutting very freely.

Common Deciduous Cypress (Taxodium distichum) makes its growth so late, and the wood consequently is so unripe, that the frosts of a severe winter destroy all but the firm wood at the base of the annual growths.

Common Yew (Taxus baccata) has the young growths of vigorous plants injured by a severe winter, having a browned appearance. With moderate shelter it does well. Its varieties erecta (stricta of some) is not at all injured, nor does the beautiful elegantissima (argentea) suffer from a severe winter with moderate shelter.

Irish Yew (T. fastigiata, also hibernica) exposed to the full east and west winds grows slowly but uninjured; with only moderate shelter it does remarkably well, its deep green close growth having a fine contrasting appearance with lighter surrounding foliage.

Taxus adpressa stricta, a cone with a broad base; does only moderately, the growths in spring having, from the effects of a hard winter, a sickly appearance.

Lobb's Arbor-Vitæ (Thuja Lobbii Menziesii) is of quick growth, and is very flexile; just the habit to withstand wind, which it does remarkably well. It is not injured by severe weather; but hares and rabbits are very fond of its spray.

American Arbor-Vitæ (T. occidentalis) is browned—brown as it usually is; but I cannot say it suffers any injury by a cold exposure. The same remark applies to its variety compacta, which is of much more bushy growth.

Siberian Arbor-Vitæ (T. Wareana) grows slowly, but is not injured. T. orientalis is not positively damaged; but it grows very little. Its variety elegantissima is very beautiful, and not injured.

Nootka Sound Cypress (Thujopsis borealis) stands uninjured, and is very free-growing and beautiful; next to Lawson's Cypress this is the finest introduction of late years. It is a handsome shrub for a lawn.

Mammoth Tree (Wellingtonia gigantea) in an unsheltered position grows slowly, and stands the east better than western winds; these having greater force drive the tree eastward, or inclining in that direction. In moderately sheltered positions it grows quickly and straight as an arrow, forming a conical rather pyramidal tree of dark green aspect, slightly browned by a severe winter. Two years ago I moved several of from 6 to 12 feet high, and though all have done fairly the removal caused them in most instances to produce cones; one, a plant of about 6 feet high, has several cones, which have every appearance of ripening perfectly. Another tree, which was not moved, had also last year a mass of cones showing, its branches really matted with them; the tree has become very sickly, in fact is only just alive. There is no disputing the fact that this tree (Wellingtonia) is very much behind many others in point of growth and suitability in a high and exposed situation.—G. Abbey.

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. I.

The man who takes London or London belongings as his theme ensures a measure of success at the outset, for what has to do with the "million-peopled city" has a national interest. In writing, therefore, upon London market gardens and nurseries, I feel that it is not at all necessary to suppose that I am addressing those only who are residents in or near the capital. It is to be hoped that many non-gardeners as well as gardeners are not uninterested in such a subject as this, upon which a good deal might be said. As some limitation is desirable, the reader will understand at the outset that my present topic is the old market gardens and nurseries, such as were existent about London fifty or a hundred years ago, or even dating still further back. The majority of these have now totally disappeared, leaving no trace except, perhaps, a name attached to a locality, or here and there a tree, standing now in smoky and melancholy guise in some back garden, the history of which no one now living is aware of, but which was once a promising shrub in a nursery where gentlemen and dames of the days of King George III. strolled up and down to admire the latest importations from foreign countries. The ceaseless demand for land at an easy distance from the great centres of city bustle, rather than a cessation of the trade carried on through these nurseries led to their disappearance, and as old proprietors retired with a competence, new market gardeners commenced business at a greater distance from town; though these also in their turn, who, starting, perhaps, twenty or thirty years ago in districts which then seemed safe from the inroads of bricks and mortar, have had to yield to the demand of the times, and migrate further off where ground is cheaper and the influence of London smoke not so marked. We find in the case of some market gardens that they struggle on for existence despite their environment with masses of buildings, as long as the lease under which they are held permits the occupier to remain, until its expiration concludes the life of the sickly plants, that have somehow gone on from year to year on short commons of light and air, and the case of the "survival of the fittest" is fully demonstrated. It is only a very few years ago, for example, since a kind of small nursery garden disappeared which occupied the centre of Ebury Square, Pimlico, the sole survivor of various nurseries formerly thriving in north and south Belgravia. Now and then a famous nursery ground has been closed, and its proprietors removing farther a-field, have carried with them the old name and its traditional repute; but instances of this kind are not numerous.

Some readers may be tempted to remark, that considering the rapid growth of London suburbs during the last score or two score years, it does not seem as if the number of market gardens and nurseries had increased in proportion. There is now certainly a larger extent of land under cultivation for market purposes within, we will say, a dozen miles of London, than there ever was before, yet it is quite true the produce only serves to supply a moiety of the population. Railway facilities for the quick conveyance townwards of vegetables and fruit have revolutionised matters, and enormous quantities of such produce reach London from distances impossible in the days of our grandfathers. Yet we must not plume ourselves that we have brought things to a state approaching perfection. Something needs still to be done in the way of moderating the rather fancy prices which certain articles fetch, and also in supplying vegetables to the table in a fresher condition than appears possible under present arrangements. I will give an instance of which any resident at the west end of London has ocular proof when he glances at the streets. Frequently at early morning he will see heavily-freighted waggons bound for Covent Garden Market, well heaped with vegetables that have been pulled or cut in the market gardens of Fulham or Hammersmith. Yet it is not always the same day that these same vegetables arrive in the shops of those who are to supply the public, and when in the shops they are liable from several causes to a further detention. Far be it from me to argue that what I may call the "middle-men," should be abolished; but it does seem a pity that the grower and the retailer cannot be brought a little closer together. Not to dwell on the question of a loss of freshness, there is a needless outlay in carrying right into London from districts like

Fulham and Hammersmith produce that has to be taken back again to Chelsea, Brompton, or Kensington to be eaten.

When I first commenced essay writing, I remember that the advice was given—advice, doubtless, well meant and not without its value—that in commenting upon some historical subject we must beware of going back too far to make a commencement. It is seldom necessary to begin with Adam and Eve, or to allude to Noah and the Ark. With this caution before me still, somehow my mind reverts to the time when London had no nurseries or market gardens—when the town, "if town it could be called, which town was not," consisted of an irregular group of huts placed on the margin of a piece of water so extensive as to form an inland lake, whence, so think authorities, arose the name London, the City of the Lake. The mouth of the Thames was probably near Richmond, and this lake, part of which was shallow enough to be called a marsh, overspread those Surrey districts contiguous to the Thames which we now know as Lambeth, Battersea, Wandsworth, and Southwark, behind which rose the Surrey hills mostly clothed in wood. By the way of Greenwich and Plaistow, past Kentish localities that are even yet marshy, the inland waters reached the sea, flowing irregularly along a track several miles across between the higher grounds of Kent and Essex. Finsbury and Fenchurch tell us where marshes were situate to the north of the Thames, but the greater part of the land in this direction was forest. Our worthy British ancestors had little idea of cultivating the soil, living mainly by the produce of the fishery and by the chase. No doubt they qualified the animal diet at times by eating herbs raw or rudely cooked, the wholesome or injurious qualities of wild plants being discovered by experiment.

The Romans unquestionably were the first horticulturists of London, for though long renowned as a hardy, self-denying race, a people of iron-like temper and power, by the time they were dominant in Britain the Roman empire was verging towards the age of luxury. Having colonised London, the Romans speedily set about the improvement of the town, and by artificial drainage they reclaimed much fertile land and brought it under cultivation. According to one list, more or less correct, they introduced the "Plane, Lime, Elm, Poplar; also the Pear, Damson, Cherry, Medlar, Peach, Apricot, Quince, Fig, Walnut, and Chestnut; as well as various Roses and other flowering plants and herbs." Though subsequent events under Boadicea and others brought destruction to the Roman residents and the fine gardens they laid out in London, still there was from that period an onward movement in the way of metropolitan flower and fruit growing. Incidentally it may be noted, that as we might conjecture from the descriptions given of the locality in the early centuries of Christian era, the climate of London was more moist and warm than in later times.

Passing on, then, for contrast not to our own day, but to a period of some sixty years ago, we read that by the best calculations about twelve thousand acres of land in Middlesex alone, not to speak of Surrey, were cultivated in order to supply the metropolis with the produce of the garden and orchard. It is not so ascertainable what extent of market gardens lay on the Surrey side at the beginning of this century—by conjecture there were two or three thousand acres at least, laid out there for the same purpose—but the bulk of the supply for London needs of this sort came from Middlesex. Across the river, even when Her Majesty the Queen came to the throne, the growth of London had been insignificant, though under the Georges it had spread northward, eastward, and westward. The old distinction between London and Southwark was kept to with some tenacity, and residents in the "Borough" scarcely considered themselves Londoners. It is in Kent and Surrey that market gardens have shown a rapid tendency to increase, as Middlesex became gradually, in the suburban districts, less available to those cultivating land with a view to large profit. One author, I may observe, makes out that those who had merely market gardens did sixty years since get an average profit of more than 50 per cent., and nurserymen must have cleared more in spite of fluctuations. The advance in the value of labour and a reduction in retail prices must have tended recently to lessen profits; but then, again, we now see a variety of improvements in cultivation are pretty generally adopted. Hundreds of years ago there were some sagacious enough to note how extremely suitable the land near London was for horticulture, not only from the soil being much of it of a loamy nature and mostly well drained, but, in addition, intersected by numerous small rivulets flowing towards the Thames; also, as Brewer observes, there is an absence of inconvenient ridges, nor do stones crop-up too profusely.

Old Nordeu's comments on the Middlesex garden land are quaint. He admits that the roadways in the country, however, were far from being in a desirable condition. "This so fruitful soil," says he, "does not yield comfort to the wayfaring man by reason of the clayish nature of the soil, which after it hath tasted the autumn showers waxeth both dirty and deep, but unto the husbandman it is a sweet and pleasant garden in regard to his hope of future profit. For

> 'The deep and dirty loathsome soil
> Yields golden grain to painful toil.'"

And there was a time when the vicinity of London had many corn fields besides market gardens; the corn coming to maturity several weeks earlier than in the adjacent counties. —J. R. S. C. .

GREYA SUTHERLANDII.

Among the many important contributions to botanical science for which it must ever be indebted to the amiable and lamented Dr. Harvey, his "Flora Capensis," or Plants of South Africa, is not the least important. While engaged in its preparation he was one day sitting in his rooms in college with some dried specimens of South African plants lying before him. With one of these, as Dr. Moore of Glasneven happened to call on him, he just then appeared to be specially occupied. Handing the specimen to him, coupled with the remark that some eminent botanists with whom he had been in communication with regard to it were puzzled as to the order to which it should be referred, he asked Dr. Moore to look at and say where he thought this interesting nondescript should be domiciled. Having examined the specimen carefully, Dr. Moore returned it, confessing at the same time that he was a good deal puzzled, but that he thought, if not actually belonging to, it came very near Saxifrageæ. "Good," replied Dr. Harvey, "it is exactly there I have placed it." While they were speaking Dr. Moore noticed something like seed or a seed capsule, we are not sure which. This was promptly laid hold of, carried home to Glasnevin, sown, and the result was, raising in that establishment—for the first time in Europe—plants of Greya Sutherlandii, than which we believe a more telling or more sensational subject has not been or could be taken in hand by the intelligent and high-class plant-grower. For the first time in Ireland this remarkable plant has quite recently flowered at Glasnevin. This and once at the Chelsea Botanic Garden are the only occasions on record, we believe, of its flowering in Europe.—(*Irish Farmers' Gazette.*)

[It does not belong to the natural order Saxifragaceæ, but to the Sapindaceæ. A very good portrait of the specimen which flowered at the Chelsea Garden is in the "Botanical Magazine," *t.* 6040.—Eds.]

CONIFERS FOR EXPOSED SITUATIONS.

Mr. Abbey should add Pinus insignis to his list of Conifers for exposed situations, if near the sea or in a mild climate. It is undoubtedly the finest and most distinct of all Conifers for such localities. Its rapidity of growth is greater than that of any Fir I am acquainted with, and its bright lively green colour and dense though free habit of growth render it one of the finest, if not the finest, of the Pine tribe. When once established its hold of the ground is such that no wind uproots it. It starts into growth very early in the season, and hence is apt to be injured by severe late frosts. The climate at this place is very mild, and consequently P. insignis never suffers from the above cause here.—J. Ellam, *Bodorgan.*

DENDROBIUM CARINIFERUM, *Reichenbach.*

This nigro-hirsute Dendrobium, one of the most beautiful of the genus, is very little known. It only requires to be seen to be thoroughly appreciated. It was named by Professor Reichenbach in 1869, but he does not in his description of the plant say who sent it to him. It does not appear to have been sent to the herbarium at Kew until 1873, when it was sent from Upper Burmah by Major Berkeley.

It is abundant in Upper Burmah, and it is surprising that so few plants of it find their way to England. It is probably in consequence of the plant not being well known. When out of flower it is frequently confounded with the commoner kinds

of nigro-hirsute Dendrobiums, and therefore not thought worth collecting. It may, however, be easily recognised at any time by the peculiar form of its stem, which tapers off very suddenly at the bottom, quite unlike the stem form of any of its allies.

It is nearest allied to Dendrobium xanthophlebium, but is decidedly distinct from that plant. The ground colour of the flower is ivory white, the texture of the same being thick and shining as in Dendrobium hedyosmum. The flowers are

Fig. 99.—Dendrobium cariniferum, *Reichenbach*.

beautifully tinged throughout with cinnabar red, especially so about the sepals; and the labellum is always brightly marked with the same colour; the keels of the three sepals are highly developed; the petals are cuneate, oblong, acute, reflexed.

This plant grows well on a block of wood, and is very easy of cultivation. The flowers vary considerably in colour in different plants, some plants being very highly tinged throughout with red, whilst other plants are nearly pure ivory white, the labellum only being brightly coloured. This variation of colour makes the plant all the more desirable, and when better known it is sure to become a favourite. The flowers are sweet-scented.

The drawing is taken from a plant in Major Berkeley's collection.

Sparrows.—Some time ago one of your correspondents thought that these birds were unjustly maligned. This year, for the first time I admit, they pecked out the centre of every Carnation in my garden, though the plants were in several

distinct patches. Both my gardener and myself saw them actually at work.—G. S.

THE FLAMINGO PLANT.

The collection of the brilliant Anthurium Scherzerianum is just now one of the "sights" at Messrs. Veitch & Son's nursery at Chelsea. Hundreds of fiery spathes are upspringing from the healthy plants, and will continue a blaze of beauty for months to come. The collection of this plant is exceedingly large and fine.

This plant holds the same rank in our stoves in summer that the Poinsettia does in winter, and both are alike indispensable in their respective periods. Like the Poinsettia, though a stove plant, the Anthurium is admirably adapted to conservatory decoration. It is much less tender than is supposed, and although heat is required to grow it in perfection it is quite safe in a conservatory temperature during its blooming season, and also at the resting period a high temperature is not an absolute necessity.

It is more than probable that the time will come when collections of the Flamingo Plant will be found in every garden where gay-flowering plants are required and where well-heated vineries are provided in which to prepare the plants, for experience is proving that the plant will safely pass the winter in a much lower temperature than was at first imagined, and that a high stove temperature in winter is not essential. It is a plant that should not be grown merely to represent the species or simply to add to a collection, but, like the Poinsettia, should be cultivated by the dozen or hundred, according to the demand for decorative plants during the summer months. For associating with Ferns nothing can be more effective for room and corridor decoration, and the plants will not suffer nearly so much under those circumstances as do many stove plants.

The culture of the plant is very easy. Mistakes have been made by potting it too low and in a compost too close. It is by nature an epiphyte, and is found growing on the trunks of fallen trees where Mosses and other Cryptogams vegetate. It is well to bear that in mind, as it is suggestive of the particular culture required by the plant. A suitable compost is lumpy peat, sphagnum, leaf mould, charcoal, and sand, to be mixed to form an open fluffy mass. For small plants pots must be used, but they should be more than half filled with drainage, to be covered with a flake of moss, and the plant be potted high above the rim of the pot, after the manner of Orchids. For large plants pans are preferable to pots. About four to six weeks after potting when the roots are showing through the surface cover with green flake moss, into which they will penetrate freely. They should have a high temperature at starting, and be frequently syringed. The plants grow slowly at first, but when once established they are rapid in their movements, especially if stimulated by clear weak manure water. That made from horse droppings has been found to assist the plants considerably; cow or other cooling manures are, no doubt, equally suitable, but guano is not recommended. An average temperature of about 65° is suitable, but they are capable of enduring a much lower and will also flourish in a higher temperature. We have seen them luxuriating at 80° to 90°, and looking quite happy in 50° to 60°, and have further known them to be wintered in a house which was commonly down to 45°. There is, therefore, abundant evidence to suppose that this plant is not delicate and tender, and that it may be grown in any garden which has convenience to ripen Muscat Grapes.

The extended culture of this plant is recommended as one of the finest summer decorative plants ever introduced to our gardens. The white variety, A. Scherzerianum Williamsii, now being distributed by Mr. B. S. Williams, is a fine companion plant to the above. Although the spathe is comparatively small at the present time and in young plants, it is certain to increase in size under cultivation. The scarlet species when it first bloomed at Kew had spathes of only about an inch in length, and they are now commonly seen of three times that size, and, indeed, Mr. Ward has exhibited a plant with spathes 5 inches long. This is mentioned lest disappointment be felt by observing blooms on small plants of either the scarlet species or its white variety, and which will certainly increase in size as the plants gain strength.

Anthurium Scherzerianum was discovered in Guatemala by M. Scherzer, and was subsequently found at Costa Rica by Wendland, who sent it to the Royal Gardens of Hanover, and from thence to those of Kew, where it flowered in April, 1862. It is figured in the "Botanical Magazine," vol. lxviii., t. 5319.—W.

APPROPRIATE POTTING.

Never did we see a more forcible illustration of the importance of being "well-fitted in the arts" than when we saw plants unsurpassably well grown rendered repulsive by being in vulgar, highly-reddened, common garden pots. They were in the entrance hall of a mansion. That hall was fitly furnished, everything around was congruous, neat, yet elegant. Nothing was discordant but the flower pots, they were rude and offensive both in form and colour; they were unfitting both to the place and to the plants growing in them.

Common pottery is suitable to the greenhouse and frame, though in the first-named structure, if a place in which visitors are expected to take pleasure, the plants are far more attractive if the shelves to receive them are so made that the pots are concealed, and the surface of the soil in them is covered with moss.

Fig. 100.

In the hall or corridors of a mansion the plants should be in porcelain pots. An illustration will enforce what we mean. How deprived of effect, how degraded would this Caladium appear if in a common flower pot!

It quite suffices that the plants be prepared in ordinary pots of a correct size that the pots in which they are grown may be inserted as required into the ornamental pots. No injury is then done to the roots, and it is surprising in what a small pot a plant may be healthily grown if assisted by a full supply of water—liquid manure when suitable to the nature of the plant. Preferable to common clay pots are ornamental latticework covers, or elegant designs which are now worked by the fret saw. Some of the latter are very attractive, and are permissible as substitutes for the more valuable porcelain receptacles.

NOTES AND GLEANINGS.

Lord Henry Lennox, the First Commissioner of Works, in opening to the public the garden adjoining the Bethnal Green Museum on the 19th inst., remarked that the preservation of open spaces would form a cardinal point in the policy of any Government in power. His lordship pointed out that the inhabitants of the east end of London had also Victoria Park and Epping Forest as open spaces. Mr. Samuda, Mr.

Richie, and others interested in the open-space movement took part in the proceedings.

—— Lyons Rose Show.—A great and special Exhibition of Roses will take place in Lyons on the 11th, 12th, and 13th of June next. Several new seedlings will appear there for the first time. The jury will be composed of the principal rosarians of Europe.

—— Mr. E. Bennett, recently head-gardener to the Marquis of Salisbury at Hatfield, has left that place, and is now in business on his own account at Rabley Nursery, near Barnet, Herts.

POROUS GARDEN POTS.

A writer in a contemporary journal considers it waste of time to wash pots, unless where the potted plant is to be shifted on into larger sizes. I am not going to discuss this question, but to notice that the writer quotes Dr. Lindley as having said that "experience has settled" that plants thrive as well in pots of glass or slate as of porous earthenware.

Now I ask, Is this true? because if it is the labour of watering would be much lessened, and the roots saved from the chill which constant evaporation from the sides of the pot must produce. The Chinese, I believe, sometimes use glazed pots.

In order to lessen evaporation I once smeared with linseed oil, and then painted, several pots containing Peach trees. I cannot say that the trees looked the better for it, and I have not continued the practice. In Italy, I understand, trees, particularly Oranges, are thought to thrive better in wooden boxes than in porous earthenware. The subject is one which deserves ventilation.—G. S.

[We shall be obliged by any of our readers writing to us what *practice* has taught them on this subject.—Eds.]

FLOWER MISSIONS.

[We have received letters giving us far more credit than is our due for advocating these missions, we only aided the good movement that had been commenced. We have been asked for directions how to establish such a mission, and the best answer is contained in the following letter sent to the *Times* by Mr. S. Walliker, Post-office Buildings, Hull.—Eds.]

"The work of collecting and distributing flowers for the sick and infirm poor is so rapidly spreading, and is productive of so much direct and indirect good, that you will perhaps permit me to give a few practical hints as to the commencement and the carrying-on of the work which have suggested themselves as the result of upwards of two years' experience, during which time about thirty thousand bunches of flowers have been distributed among the poor of Hull. The system adopted here has been framed with the view of saving all possible trouble to those who send, as well as to those who distribute the flowers. A depôt was selected in a central situation convenient for the reception of flowers brought by rail, boat, or carrier; it is open all day, and someone is always at hand to receive the flowers and, if possible, to return the baskets and other packages by bearer, and trays about 2 or 3 inches deep, covered with galvanised iron netting and filled with water, are kept ready to place the flowers in, so as both to refresh and preserve them. The ready sympathy of the local press was secured, and is still in active operation, and the public were requested to send flowers, made up in small posies if possible, to the depôt. To assist the public, stout hampers divided in the centre by an extra lid (the hampers cost 2*s.* 6*d.* each), with two printed leather labels, one bearing the inward, the other the outward address, are supplied to anyone who will undertake to collect and forward flowers. Small printed card circulars are at the same time sent to those who are likely to contribute to the baskets, advising them as to where they are kept and the days on which they will be despatched. A simple record of the date, the names and addresses of senders, and special remarks, is kept, and the receipt of flowers is acknowledged by means of printed post-cards, only requiring the date and address to be written. The distribution here is not confined to the public institutions, but is made also to the sick, infirm, and aged poor throughout the town. To regulate the supplies and prevent waste, printed lists giving the names of all the hospitals, workhouses, &c., and the names and addresses of all the district visitors and others who undertake to distribute to the outside poor, are prepared. These lists have seven columns. In the first, the greatest number of bunches each institution or person can dispose of is stated; the other six columns are for the days of the week. Some visitors cannot distribute flowers on certain days, and in those cases marks are printed in the respective columns opposite the visitors' names. These lists become valuable for statistical purposes and for comparison of year with year. The number of bunches, regulated by previous supplies, to be sent to each institution or person is entered on the lists, and the flowers are sent out in covered baskets (to preserve their freshness and perfume) by a little lad in uniform (a half-time school-boy), who copies on a slip of paper, for his own guidance, the names and numbers. He is paid 3*s.* a-week. When not busy he carries on his studies. During the winter months pots and pans containing mosses and lichens, carrot-tops, wheat-ears and grains of wheat, pots of bulbs, bunches of evergreens, &c., are sent out, so that there is never a week in which something is not done to cheer the poor, especially the sick, and to assure them of the loving sympathy which exists (too often latent, however), in the breasts of their well-to-do brethren. If any lady or gentleman desires any further information which I may be able to give on this subject I shall be happy to render it."

LATE-KEEPING GRAPES.

Mr. Luckhurst has not only communicated a very entertaining but a very useful article on this subject on page 365. He has taken in hand three well-known Grapes, and has communicated, especially on that fine variety Gros Guillaume, valuable information. Mr. Luckhurst will no doubt find several adherents to the estimate he has formed of Lady Downe's Seedling and Black Alicante, but he has had too much experience of the world to suppose that his remarks will carry conviction to all. This, indeed, is not possible; for so long as tastes vary, and soils exert an influence on fruits, so long will there be differences of opinion and matters for discussion as to the relative merits of Grapes.

Mr. Luckhurst commences his letter by acknowledging that Lady Downe's Seedling is generally admitted to be the best late-keeping Grape in cultivation, but doubts notwithstanding whether many of those who find it so valuable could give a satisfactory reason for the preference which they assign it. Satisfactory to whom? that is the question. I, like Mr. Luckhurst, have grown Lady Downe's Seedling, Black Alicante, Gros Guillaume, Mrs. Pince's Black Muscat, and Muscat of Alexandria in the same house; and to dispel any doubt as to the Black Alicante not being the true variety, I may say that it was had from Mr. Pearson. It is the true variety and a fine Grape, but has never given equal satisfaction with Lady Downe's Seedling.

I can give a satisfactory reason for regarding the Grape just named as superior to the Alicante, but satisfactory to whom? My employer and myself. Now, we consider ourselves authorities on those which best answer our own purpose. I think Mr. Luckhurst will not dispute that that is a practical way of judging the matter, and one, withal, that must be recognised and generally adopted.

In the first place we use but very little fuel—that is, we do not start the Vines early, but keep up a good heat during the growing season, in fact sufficient to ripen Muscats fairly well and to produce good crops year by year. Still, it is cool treatment, as very little firing is done; and while Lady Downe's Seedling is splendid in colour and quality, Alicante is comparatively washy and flavourless. It colours well and looks grandly, but it is not half so good as Lady Downe's Seedling and Mrs. Pince's Black Muscat, and hence, despite its fine appearance, Black Alicante is not regarded as the best late Grape.

Lady Downe's has small bunches, but there are a great many of them, while the berries are good, flavour excellent, and keeping properties unsurpassed. With more heat Black Alicante might be better in quality—indeed we have Mr. Luckhurst's evidence that it is; and I hope the rule will hold good generally, for in appearance it is a grand Grape, an abundant bearer, a free setter, and not prone to shank.

Under ordinary treatment I commend as late Black Grapes, Alicante to look at, and Lady Downe's Seedling to eat; not implying, however, that the former is not fit to eat, only that it is inferior to the latter.

As a Grape for sale the true Black Alicante is probably about the most profitable that can be grown. I know it has proved

itself such in two instances where all the ordinary varieties have been tested, but the owners would never eat it themselves, and it was sent to London by the hundredweight. Dr. Hogg's "Fruit Manual" states that Black Alicante has nearly twenty aliases—good proof of its worth; and after describing it the author speaks of its flavour as "similar to that of Black Hamburgh." What could be more correct? But who will eat Black Hamburgh except as a change when Lady Downe's Seedling can be had? But what does the author of the "Fruit Manual" say of Lady Downe's? I turn to page 293, and find it described as a "very valuable Grape, and may be ripened in the heat of an ordinary vinery; richly flavoured with a faint trace of Muscat flavour, but not so much as to include it among Muscats." This is equally precise, as all must know who have cultivated the Grapes, only in some soils the Muscat flavour is much greater than in others, but in none is the Grape destitute of that fine aroma. The work also says that the berries are increased in size but not improved in flavour when grafted on the Black Hamburgh, while on Gros Guillaume it does not succeed so well, but the flavour is improved. On the first stock I have tested it but not on the second, and Mr. Luckhurst may do much to rectify one of the only faults he can bring against Lady Downe's Seedling by working it on the Black Hamburgh stock; and the other—scalding, will, as I have found, be less serious than when on its own roots.

Mrs. Pince's Black Muscat I have found under ordinary temperature to be infinitely superior to Alicante in flavour but deficient in colour. It requires more than Hamburgh heat, must carry plenty of foliage, and have good support at the roots to colour it well. It is then a splendid Grape. Its failing point is in being slow to colour.

I now turn to Gros Guillaume. This, as Mr. Luckhurst observes, is a splendid variety, and, as he opportunely suggests, it is only shy when improperly treated. Pruned on the orthodox spur system and with only ordinary heat it will seldom be satisfactory; but afford it heat, light, and room, and it will return such bunches that no black Grape can equal, and in flavour it is difficult to surpass, only let it hang until February or March. This is a most valuable late Grape, and when pruned long, and young shoots are trained-in annually, it seldom fails to carry a sufficient number of enormous bunches to yield a heavy crop. It is little use attempting to grow this variety where it cannot have room to extend, light to perfect, and heat to mature its growth; but these necessary conditions provided, it will fruit as a matter of course.

But why do we not hear more of Madresfield Court as a Black Grape to succeed the Hamburgh, and to use until the very late sorts are in perfection? It is one of the finest Grapes ever raised; it will ripen and colour in an ordinary temperature, and is a good cropper, free setter, and of superior flavour. —A Northern Gardener.

I am glad Mr. Luckhurst has brought the subject of late-keeping Grapes before the public. I have often wondered how it was that Lady Downe's Seedling should be placed at the head of the list of late-keeping Grapes. I can bear out all Mr. Luckhurst has said about Alicante and Lady Downe's Seedling. My late vinery is similar to that of Mr. Luckhurst; it contains the following varieties—Lady Downe's Seedling, Black Alicante, Mrs. Pince, Muscat of Alexandria, Duchess of Buccleuch, Gros Guillaume, Madresfield Court Muscat, and Bowood Muscat.

I suffer in the same way as Mr. Luckhurst, for in very hot weather the Lady Downe's becomes almost baked, and sometimes to such an extent that many of the bunches are almost skeletons after the thinning. This has occurred, and with abundance of air circulating through the house, from early morning until late in the afternoon. This scalding has never happened to Alicante. Out of all the Grapes I have here enumerated Alicante is the best late keeper. Mine, I feel satisfied, is the true kind, and answers exactly to the description given by Mr. Pearson; indeed I believe the Vines were supplied by Mr. Pearson.

To grow the Alicante successfully it will bear as much forcing as a Muscat of Alexandria. I have one Alicante planted in the first vinery, and this Vine is always more satisfactory than any of the same kind in a late house. The Grapes on this Vine are always left hanging until we want to prune the Vines, we then place them in bottles. Usually these Grapes are always in good condition after the same kind grown in a late house have been used. This is a convincing proof that late-keeping Grapes are better with a little forcing, and, as my late house contains such a mixed multitude, I usually assist them with a little fire heat.

I may state that the quality of the Alicante grown in an early vinery have always been superior to those grown in a late house.—G. R. Allis.

A REMINDER—COLEWORTS.

On or about the 30th of May I have for a number of years made it a practice to sow Early York Cabbage and the Dwarf Green Colewort. But what a simple subject that is to write about. True, it is simple, but then it is, like many other simple matters, very useful. It often requires the withdrawal of a simplicity of life to render its value appreciable. When we have anything in abundance its value is apt to be underestimated, but take it away for a season and the blank created is every day pressing its unwelcome presence on our notice. I was for one season without these simple necessities. I omitted to sow the seed, and my neighbours, like a great many neighbours of other people, had not recognised the value of the crop, and I could not obtain a supply of plants. I think as long as I am a gardener I shall not again forget to sow the seed, as my well-remembered blank is always a reminder of the importance of doing so somewhere near the time stated.

I felt the loss in more ways than one. My employer and his family missed the usual autumn supply of delicious vegetables, and for which no substitute was admitted to be satisfactory, and the winter greens had to be commenced, and a great portion of them consumed a month before the usual time, and a spring scarcity of vegetables followed the autumn disappointment, and all from the omission of the simple subject of this reminder. A neglect of what may appear trivial at the time may thus result in disappointment of no small magnitude, and be a source of discomfort, if nothing more, several months afterwards, and when too late to rectify the mistake.

Plants from this sowing not only give valuable cuttings in the autumn, but they are ready for planting in ground made vacant by the removal of early Peas, Potatoes, &c. Such ground seldom needs to be dug, but the plants are simply dibbed-in 15 inches apart, and the autumn rains may be depended on to give them support and make their produce sweet. They are used, and the ground again ready for winter digging and spring crops; also the winter greens proper are really preserved and prolonged for winter and spring use, which is a matter of no small importance where, as is often the case, ground is scarce and household wants are not easy to meet and satisfy.—A Kitchen Gardener.

THE GARDENERS' LESSON.

Two gardeners had their crops of Peas killed by the frost. One of them was very impatient under the loss, and fretted about it very much. The other went patiently to work at once to plant a new crop. After awhile the impatient fretting man went to his neighbour. To his surprise he found another crop of Peas growing finely. He wondered how this could be.

"These are what I sowed while you were fretting," said his neighbour.

"But don't you ever fret?" he asked.

"Yes, I do; but I put it off till I have repaired the mischief that has been done."

"Why, then you have no need to fret at all."

"True," said his friend, "and that's the reason I put it off."

NOTES on VILLA and SUBURBAN GARDENING.

Arranging and Planting Bedding Plants.—How pleasant it is to many an amateur, as well as the gardener, when the time has arrived for it to be considered safe to trust his stock of plants out in the beds. The anxiety brought about by having to nurse a stock of plants for so long under cover, and the amount of labour attached to them while so situated, turns into a sense of relief at the thought of being able once more to have them put into their proper places. Let us see if we can suggest a few simple arrangements for those who are not initiated.

Without entering into particularities, which would not be profitable, I presume there will be two main objects looked for or aimed at—that is, arrangement to be seen close at hand, or more distinct and contrasting to be seen from a distance. This last mode is found most popular in the amateur's garden, because as a rule the beds are small and borders narrow, and the colours to be arranged are but few. It is, however, always well to make

as much variation as possible, because variety, even in a small place, has a charm of its own.

A few simple modes of arrangement may here be noted; for instance, a bed of any shape having yellow Calceolaria for a centre surrounded with Scarlet Geranium Tom Thumb, and edged with Cineraria maritima or Cerastium, would look well. As another example take the Scarlet Geranium for a centre, and put the Calceolaria next, and edge the whole with Purple King Verbena or Lobelia speciosa. In either of the above, if Calceolarias are not grown, the yellow Tagetes will answer well. Another arrangement is to plant Amaranthus melancholicus, Coleus Verschaffelti or Perilla for a centre, surrounding these with Geranium Christine (pink), with an edging of Golden Pyrethrum, and there will not be much wrong. Among Silver-variegated Geraniums we may take Bijou or Flower of Spring as a type; place either of these in the centre of a bed surrounded by a band of any dark-foliage plant, such as Perilla or Beet, and then edged with Golden Chain. The above are all contrasting colours, and if the beds are large enough so as to admit of a good quantity of each being planted they will be particularly gay. But it may be that there is not space for these colours, then two must be used, taking care that the bed is properly divided for each colour to be shown off to advantage. The centre colour ought to occupy fully two-thirds of the bed; arranged thus they would look well. Scarlet Geranium, such as Cybister or Stella, edged with Calceolaria or Golden Chain; Coleus Verschaffelti edged with Cineraria maritima; or make Centaurea candidissima a centre, and edge with Mrs. Pollock Geranium; or take either of the last-named and plant in the centre, and they will be pleasing with an edging of blue Lobelia. Again, I admire a bed planted with Silver-leaved Geranium Manglesii and edged with Verbena pulchellum, or yellow Calceolaria edged with Purple King Verbena or Viola cornuta.

Now, if we come to a more harmonious arrangement we may place a pink in the centre, such as Christine, and edge with scarlet; or a pale yellow in the centre, such as Calceolaria angustifolia, and edge with the deep yellow Gazania splendens; or a blue Lobelia edged with the light-flowered Lobelia Paxtoni. Such arrangements are very necessary at times in a design to bring out the principal features in an arrangement of a more complicated nature.

Speaking generally, the plainer the shape of the bed the easier it is to plant, and the better will its arrangement be seen. For my part, though I like strong contrasts which can be seen at once, I have also a special liking for soft combinations of colour. There seems to be in these something to study, and which the more one examines the more does their beauty come to light.

The amateur, who must at times be sorely puzzled to know what is best to grow in his small place, will find some consolation in knowing that there are now many plants used for bedding of a dwarf habit, such as Golden Pyrethrum, Golden Chickweed, Mesembryanthemums both variegated and green, Lavender Cotton, the golden and silver variegated Thyme, and several others which occupy but little space during winter, and some of which are comparatively hardy. I ought also to mention Sedum elegans and the Variegated Grass, Dactylis glomerata variegata.

Now, if an arrangement totally different from that named above be wanted, by the addition to the above list of Alternantheras spathulata and magnifica, the amateur may work out almost any design his taste may lead him to in what is called carpet bedding, and thereby add an extra charm to his place, giving also a kind of relief to the blaze of colour produced by the ordinary flowering plants. These few remarks are intended as a guide or starting point for the amateur's use, not by any means exhaustive of the general system of bedding.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

UNTIL last Thursday the weather had been warm by day, the thermometer ranging from 70° to 80° in the shade, and the nights were comparatively mild, so that all growing crops including the Potato have made much progress. In earthing-up rows of Potatoes the mould should not be drawn-up with the hoe from each side to form a ridge close to the stem of the plant, as this plan throws all the rainfall into the bottom of the trench. The proper way is to draw-up the mould to form a ridge on each side of the row, so that a shallow furrow may be formed where the Potato plants are growing.

Asparagus is now producing abundantly, the beds requiring to be cut-over every morning. It has been recommended by some to water the beds at this time, but unless the season has been exceptionably dry but little benefit would result from it, and if the weather should set in cold the water would do harm by chilling the ground, which would certainly check the growth. No amount of frost would be likely to injure the roots of Asparagus when dormant in winter, but the young succulent growth are easily injured; cold weather checks their growth, and spring frosts kill them to the ground. Water may generally be applied with advantage during the summer months when the plants are in full growth; according to the strength of the plant in summer so may the quantity of the next year's crop be calculated upon. Manure water may be applied with advantage. We have seen excellent heads produced from gardens near the seacoast, and where annual dressings of seaweeds could be applied to the beds. Salt has also been highly recommended as a manure.

We are thinning-out crops of Onions, Carrots, Parsnips, &c., and hoeing between the rows. Wherever opportunity offers ground is prepared for succession crops, and the ground is hoed wherever there is the least appearance of weeds. Now is the time to have the garden clean and in good order, as, if weeds are allowed to make any headway now, there is little chance of completely eradicating them during the season.

PINERIES.

The usual time to pot suckers is in August, from the plants that ripen their fruit through the summer months; but if a few strong suckers can be potted now into 6 and 7-inch pots, the pots plunged in a brisk bottom heat, and a minimum temperature of 70° kept up, the pots will soon become filled with roots, when they may be repotted into 10 and 11-inch pots. These they will fill with roots by the autumn, and the plants will be of a fruiting size by the end of October. After they have had a rest up to the first week in January they may be started, and will produce fruit in June and July, and plants of this age produce finer fruit and do not require nearly so much space as those kept through two winters. When their management is understood Pines are easily cultivated. The turfy part of medium clayey loam five parts, one part rotted stable manure, two pecks of charcoal broken into pieces from the size of a boy's marble to that of a pigeon's egg, and one peck of half-inch bones, will grow the plants well.

Use clean pots, well drained; over the drainage place some turfy loam from which the finer particles have been beaten and sifted. The compost must be rammed-in rather firmly with a wooden rammer. The same treatment is again necessary when repotting. When the plants are repotted it is an excellent opportunity to add fresh material to the bed and to turn it over, mixing the fresh tan well with the old.

PEACH HOUSES.

In the late house there is plenty of work now tying-down the shoots to the wires. Avoid by all means crowding the trees with too much young wood. It is the nature of Peach trees that are trained on the fan system to become bare of young wood about the centre of the trees. This may be remedied by judicious cutting-back, and also by training the young wood over the bare stems of the branches. The Peach trellis ought to be furnished with bearing wood equally distributed over the whole surface of the trellis. It is necessary to again draw attention to thoroughly syringing the trees night and morning. The house may generally be shut up about 5 P.M., and that is the best time to syringe. In dull cold weather it may be as well not to syringe at night, as mildew may attack the trees; if it does, dust the leaves affected with sulphur at once. When the trees are in full growth they require as much water as Vines.

Outside borders are not likely to suffer for want of water, but should the roots be inside water must now be freely applied, and dress the surface with rotted manure; this causes the rootlets to work up to the surface, where they receive the benefit of the dressing.

In the earliest house, where fruit is ripening, the work is now pleasant enough if the trees have been well managed. Leaves that are shading the fruit should be pushed aside or picked off to allow the sun to act upon it. Plenty of air ought to be admitted night and day, and if the roots had a liberal supply of water before leaving off syringing no more will be required until all the fruit is gathered. If red spider was left on the leaves at that time they will play sad havoc with the leaves before all the fruit can be removed, so that they may again be syringed.

PLANT STOVES AND ORCHID HOUSES.

It is necessary to warn cultivators of the insect pests that increase so rapidly at this season. Red spider is even more insidious in its attacks than the dreaded mealy bug, and many plants are seriously injured before the enemy is perceived. Dracænas and Palms must be watched for it, and sponged if necessary with soapy water. The Cocoa-nut Palm is a favourite haunt of red spider, but the broad leaves can be readily washed with a large sponge. But the plants ought also to stand in a position where they can be syringed daily. Occasionally sponging the foliage of Dracænas, especially such useful decorative sorts as D. terminalis and D. Cooperi, is adopted and recommended, as the leaves are more brilliant by the cleansing.

Attend to training the climbers trained to the roof. One of the most useful of stove climbers is the Clerodendron Balfourii; this is never attacked by insects, and at the present time it is a mass of bloom. Stephanotis floribunda is another excellent plant to train to the roof. The flowers are prized for all sorts

of decorative purposes. It will do well cultivated in large pots, but it is far better to plant it out in a well-drained border, as the dark green large glossy leaves will testify, and the flowers are as large again. Mealy bug is a very troublesome pest on this plant. As this plant is invaluable where quantities of cut flowers are required, it is worth while to spend some time in cleaning it; the bug must be destroyed by hunting them up and picking them off by hand, and by washing with a sponge and soapy water. We do not allow the growths to become crowded or intertwined with each other. As nearly all the climbing and many other plants are now in flower, and as it is very desirable to retain their freshness as long as possible, just sufficient artificial heat is kept up as will raise the night temperature to 65°, the atmosphere is a little drier and more ventilation is allowed by day, but as the south-west winds have prevailed this week it has been necessary to be cautious.

Ferns and foliage plants are frequently syringed with tepid water, taking care not to wet Gymnogrammas, as the gold and white powder being washed about quite spoils the fronds. Orchids in flower are removed to a cooler house, where the bloom lasts much longer than it does in the stove.

FLOWER GARDEN.

By the time this is in print nearly all the bedding plants will be out, the exceptions being the more tender plants, such as Alternantheras, Coleus, Iresine, &c. We always bed out early, seldom later than the second week in May, but the plants are strong and well inured to the weather. Our belief, and it receives confirmation annually, is that one good plant that has not been too closely crowded with others is worth six weakly specimens that require half the season before they become established. High winds have been a source of annoyance to us while planting, but in all other respects circumstances have been favourable.

Now is the time to attend to Violets. The best runners should be selected and planted in rich soil, the leaves should be washed in soapy water to destroy red spider. In our light gravelly soil this pest is very troublesome; in dry seasons the leaves on the old plants have been quite destroyed by midsummer. Lee's Victoria Regina, figured some time ago in this Journal, should be extensively grown. The flowers are very large, richly coloured, and highly scented.

It will now be time to plant out Dahlias. If the plants are still in cold frames the lights should be off night and day, unless there are signs of a frost. The permanent sticks should be placed to the plants as soon as they are planted. Of course the ground was prepared in the autumn by being deeply trenched and well manured; nevertheless a rich compost should be placed round the roots to start the plants into growth at once.

Hollyhocks—if the spikes are wanted about the last week in August or early in September—should now be ready to put out; indeed they might have been planted with advantage earlier in the month. In Scotland we used to plant about the last week in April or the first in May for the September shows, and the plants were propagated in the previous autumn. In the south plants propagated by root-grafting in spring make the best spikes. The ground for them requires to be prepared as for Dahlias, and the treatment in other respects is similar. Red spider destroys the leaves if it is not washed off by syringing.

We have finished potting the Auriculas, the plants are now rooting freely. No mistake will be made in potting any class of flowers if the operation is performed at the time the roots are active. Any plants with long stems were cut over at the surface of the ground, the head potted in a small pot and placed under a bell-glass; this prevents the leaves from flagging, as if this occurs the cutting or crown will not do well. Many offsets start from the headless stump and soon form strong cuttings. —J. Douglas.

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Crystal Palace Company.—Flower Show, May 29th; Rose Show, June 26th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.

Coventry.—May 31st. Mr. T. Wigston, 3, Portland Terrace, Lower Ford Street, Sec.

Leeds.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.

Burton-upon-Trent.—June 16th. Mr. Wm. Shave, Bond Street, Sec.

Jersey.—Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon.-Sec.

York.—June 16th, 17th, and 18th. Mr. Jno. Wilson, 13, New Street, York, Sec.

Glasgow.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.

Exeter (Rose Show).—June 18th. Mr. J. N. Gray, Queen Street Chambers, Hon.-Sec.

Fareham.—June 23rd. Mr. H Smith, Sec.

Stowmarket.—June 24th and 25th. Mr. S. Prentice, Hon.-Sec.

Reigate (Rose).—June 26th, 1875. Bushby Britten, Esq., Hon.-Sec.

Wisbeach.—June 30th. Mr. C. Parker, Hon.-Sec.

Maidstone.—(Roses), June 30th, at Vinters Park. H. Benstead, Esq., Hon. Sec., Rose Club, Mill Street, Maidstone.

Norfolk and Norwich Horticultural Society.—Rose Show, June 30th. E. A. Field, Hon.-Sec.

Birmingham.—July 1st, 2nd, 3rd, and 5th. Mr. Quilter, Aston Park Sec.

Spalding.—July 1st and 2nd. Mr. G. F. Barrell, Hon.-Sec.

Brockham Rose Show.—July 3rd. Rev. Alan Cheales and Charles Mortimer, Esq., Hon.-Secs.

Southgate.—July 3rd. John Miles, Esq, Hon.-Sec., Southgate, N.

Durham and Northumberland.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.

Grantham.—July 7th and 8th. Schedules, &c., from Mr. Lyne, Bookseller.

Winterton.—July 7th and 8th. Mr. McCallum, Sec.

Frome (Rose).—July 8th. Mr. A. R. Baily, Hon.-Sec.

Kilsby.—July 8th. Sec., Mr. C. E. Bracebridge.

Nottingham.—Rose Show, &c., July 8th, 9th and 10th. Apply to Alfred Kirk, Municipal Offices, Nottingham.

Oxford (Roses).—July 9th. Mr. C. R. Ridley, Hon.-Sec.

Heworth.—July 14th. Mr. R. H. Feltoe, Heworth, York, Hon.-Sec.

Oundle.—July 14th. Mr. Alfred King, Sec.

Tonbridge.—July 14th. Mr. W. Blair, Free Press Office, Hon.-Sec.

Wimbledon.—July 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Sunnyside, Wimbledon, Hon.-Sec.

Darlington.—July 16th, at Southend. William Hodgson, Sec.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Books (*A New Subscriber*).—Our "Garden Manual" contains directions relative to all you mention. You can have it free by post if you enclose twenty postage stamps with your direction.

Summer-pinching Fruit Trees (*F. J.*).—Leave the trees until the end of June. Apple trees are now in full flower. It is best not to pinch any trees until the fruit is set. We have pinched a few Pear trees on the walls that have no fruit upon them.

Peach Leaves Partially Decayed (*Kingsbridge*).—The roots do not supply a sufficiency of sap to maintain growth. Water with weak liquid manure copiously, and put mulch over the surface at night, but removing it during sunny days. We cannot guess about holes in Vine leaves.

Peach Leaves Blistered (*An Old Subscriber and L.*).—The blistering is occasioned by exposure to very low temperatures, such as night frosts. Protection is the only prevention. Pick off all the blistered leaves, and take care that all the aphides on them are destroyed with them. The shoots should be thinned-out, so that the young growth may be laid-in thinly to mature for the next season's crop; the fruit should also be thinned, leaving a fruit to about every square foot of wall surface. If you wish a fruit to remain at the base of a shoot to be removed, pinch that shoot in preference to removing it altogether, and the few leaves left will nourish the fruit. Amateurs' Peach trees are frequently overcrowded by laying the young wood in too thickly.

Rose Aphides and Mildew.—In answer to "*D. J.*" the Rev. Mr. Radcliffe writes:—"I kill the first and last broods of aphides with finger and thumb, and then syringe. They first appear on the hot south walls. I immediately kill them. The first brood proceeds from eggs laid in September. The September aphides are oviparous, and the spring and summer broods are viviparous. I believe, if not interfered with, there are ten generations in a season. As regards mildew, I simply cut off the twig and burn it before the parasitic fungus has time to spread. I do the same with orange fungus. By destroying the egg-layers in September you will stop much spring and summer mischief. My chief remedy for insects is cold water and squeezing.—W. F. Radclyffe."

White Parsley.—"Your correspondent, 'Sigma,' is deceived respecting the 'white Parsley' used by chemists to flavour essences. He has probably seen it in the bottles, but it is only the ordinary Parsley used to colour, not to flavour essences. The chlorophyll, or green-colouring matter, of the Parsley, being extracted by the spirit, leaves the Parsley blanched. It is generally used for the mint essences.—A. Deck."

Echeverias and Sempervivums (*Miles*).—When planted in the beds they are better turned out of the pots, as they grow much more freely. There is no advantage in putting them out in the pots, unless the plants may be as large as is wished, and the planting with the pots acts as a check to growth, also the plants are more safely removed from the beds in the autumn than plants which are taken up and potted.

Peach Leaves Blistered (*Idem*).—Insects, probably aphis, are the cause of the leaves curling, or it may have arisen from the blistered state of the leaves occasioned by cold. The worst infected leaves we should remove, and with warmer weather the leaves will come all right. There is no remedy for blistering of the leaves but more efficient means of protection to the tender growths from frost or cold weather. For the aphis no remedy is so effectual as a thorough syringing with tobacco water, the juice diluted with six times the volume of water, and each gallon of the diluted liquid holding in solution 2 ozs. of soft soap.

PALMS FLOWERING IN THE OPEN AIR (*L. M.*).—We presume they are Chamærops Fortunei which is a fine plant for sheltered positions. We do not think they would be injured by flowering, which we should certainly allow, and should be glad if you would inform us the after-state of the plants and the result as to fruit. It is not common for this plant to flower outdoors in these islands.

COOLING'S MATCHLESS BROCCOLI (*J. W. K.*).—It headed with us this year at the middle of April, and is only just over. It is a desirable kind with close heads. Its usual season is the close of March or early in April.

HERBACEOUS PLANTS FOR FORCING (*M. A. P. B. L.*).—Dielytra spectabilis, Spiræa japonica, Lily of the Valley, Solomon's Seal, Helleborus niger and var. major. These and Pinks we recommend, but the two latter are not of much use for cutting. Other plants for forcing, and admirable for cutting, are shrubs, as follows:—Azalea ponticum vars., Deutzia gracilis, Kalmia latifolia, Lilacs Charles X. and Persian, Rhododendrons, Prunus sinensis flore-pleno, and Roses. The treatment of the whole has been from time to time given in our pages.

PLANTING ECHEVERIAS (*W. B.*).—In a soil such as yours the raised parts of the bed may, after the proper shape is given, the walls builded firmly, and the plants put in, be thinly coated with Roman cement mixed about half and half with soil, and a thin layer or coating of it laid on the raised parts just covering them, and whilst wet or soft sprinkle it with soil to prevent the cement being noticed. Or a bank may be built of road scrapings, soil, and cow dung, in equal parts made into a mortar.

SEMPERVIVUM SEEDING (*Idem*).—Keep it in the house in a light airy position and fertilise the flowers, not potting the plant, or at least not until the flowering is past and the pods of seed are well developed. This even we do not advise unless the plant is pot-bound.

BUDS MAGGOT-EATEN (*C. A. J.*).—We fear that white hellebore powder would not destroy the grubs, for they are within the buds of your Apple, Pear, and Rose trees. Every bud attacked should at once be picked off and destroyed to prevent the small moths being produced from the grubs, which would give birth to more grubs.

SHALLOTS *versus* POTATO ONIONS (*J. H.*).—Shallots have much smaller and more leaves than Potato Onions. The appearance of Potato Onions does not differ very materially from Portugal Onions.

ROSES FOR WEST WALL (*E. G. H.*).—As you say Teas will not do, the following Hybrid Perpetuals may answer:—Alfred Colomb, Baron de Bonstetten, Capitaine Lamure, Charles Turner, Climbing Victor Verdier, Duke of Edinburgh, Edward Morren, General Miloradovitsch, Glory of Waltham, Louis Van Houtte, Madame Canrobert, Madame Hippolyte Jamain, Madame Laurent, Paul Neron, Princess Beatrice, and Thomas Methven.

LILY OF THE VALLEY NOT FLOWERING (*Idem*).—They are too crowded and cannot perfect the crowns. The situation is also unfavourable. They do best in slight shade, as that of a north border, and should be planted in clumps of about six crowns each at 9 inches apart, in rows a foot asunder, and four rows in a bed, and one row left out. The soil should be rich and light, watering freely in dry weather during growth. The planting should be done in November. Thinned-out to clumps of about six crowns each and 9 inches apart the old plantation may remain, giving a top-dressing of rich compost.

SNOWDROP TREE (*F. A. B.*).—It is the Halesia tetraptera, and so named in honour of the venerable Stephen Hales. It is a native of South Carolina, where it flourishes by the sides of shaded rivulets.

PEA TRELLISES (*G. B.*).—We have never used those made by Mr. Burns, and advertised by him. We have used such trellises and found them preferable to pea-sticks in most respects.

WOODLICE IN GREENHOUSE (*C. L. W.*).—Place a little hay loosely round the sides of the structures they infest, and in the morning pour boiling water down the walls a little above the hay. This, of course, kills all it touches, and repeated several times will entirely destroy them, though they will in time reappear. When this method cannot be adopted on account of the boiling water being likely to injure the plants, your best plan will be to place a boiled potato wrapped lightly in a little hay in a small flower-pot, and put the pot on its side where the woodlice are troublesome. This trap should be examined every morning, and the woodlice secreted in the hay shaken into boiling water. A number of traps of this kind, put down every night and examined in the morning, will soon thin their numbers.

INSECTS ON CURRANT TREES (*H. W.*).—The caterpillars found on your Currant trees and Gooseberry bushes are the larvæ of a saw-fly, Nematus Ribesii. Hand-picking is the best remedy, but you may try syringing them with lime and soot water mixed with soft soapsuds; also you may burn weeds to windward of the trees. When the grubs fall to the ground it should be well battered flat with a spade to kill them. In the winter the earth under the trees should be removed to the depth of several inches so as to carry away the chrysalides.—I. O. W.

INSECTS (*C. J. H.*).—You ask for much information about the grub sent, but do not say where it was found or what it had attacked to enable us to answer you properly. It is the larvæ of the common daddy-longlegs. Water the ground with lime water and soapsuds or gas-tar water now, and employ children to catch the flies when they arrive at the winged state.—I. O. W.

POULTRY, BEE, AND PIGEON CHRONICLE.

EGGS AND EAST WIND.

MR. ROBSON reminded us in that part of our Journal devoted to horticulture of the many benefits we indirectly receive through the beneficial influence of the much-reviled east wind acting on the soil. It is a word in season, for if there is one saying more than another that I have become weary of this spring, it is that popular but miserable and fallacious old distich which every second person one meets thinks it proper to shout in one's face as an accompaniment to the usual remarks about the coldness of the season. If the gentle Elia had only been a denizen of the country instead of the town, I am sure that among his prattlings about popular fallacies he would have given us something in refutation of this crusty rheumatic old bachelor's proverb about the east wind. I am persuaded that if we could trace it to its source we should find it issuing from the querulous lips of some gouty old gentleman laid-up with a roll of flannel round his toe. Do you doubt it? Nay, I am sure that no gardener ever gave birth to such a libel. The gardeners' proverb is, "A bushel of March dust is worth a king's ransom." And how will you have the dust without the east wind? It might perchance have been jerked out by some disappointed poultry fancier, some ancient Briton or noble Roman done out of his early brood of fighting Game chickens, and in this case I can fully sympathise with him, for we poultry-keepers learnt early to regard the east wind with anything but friendly feelings; but no gardener would ever so sweepingly condemn that which enables him to lay a good foundation for all his hopes. No, no, let us speak the truth, which in this, as in so many cases, lies betwixt and between the two extremes.

The east wind is a good friend under a rough exterior. He does much useful work, but he does it in a very unpleasant way. He brings blessings to the multitude, but knocks on the head a select few. He romps with the strong and healthy, but the delicate find his horseplay rather too much for them and collapse. This is one of the instances in which an all-wise Creator has judged it better that the few should suffer for the benefit of the many. In my own case my heart is divided. As a zealous horticulturist I cling to the east wind as a faithful but rather overbearing friend; as a rabid poultry fancier I have a sort of idea that I could dispense with it altogether.

What in the world is it it does to the eggs? Can't somebody tell us? Is there no way (I speak as a poultry fancier) to defeat our insidious opponent? Why should he be permitted to addle all our prospects any longer? You have doubtless had it explained to you by knowing people that our enemy is so mischievous because he is so dry, and that as we cannot make the wind wet we must make our eggs wet. Did you find the water cure answer? I never did. Wet or dry my eggs will not hatch at certain times, and wet or dry at other times they will. You may put turf at the bottom of your nests, you may sprinkle your eggs, damp the breasts of your hens, and pour water round your sitting places, but if the east wind has had its way you will have no chickens. Why is it? Now I am afraid some will think me a heretic; but I will tell you the conclusion I have come to: that constant damping as an antidote against east wind is a fallacy—useless, and in some cases (that is in very cold weather) worse than useless. "What, you ignoramus!" says one, "don't you know that hens which steal their nests always bring out the best broods? and they sit their eggs on the damp ground." No, sir, I don't know it. I have lately heard of a hen which early this season stole her nest, and sat in the manner described, but she hatched no chickens at all. I have heard, too, of hens choosing hayloft and other dry places for their nests, and having good broods.

I admit that hens which go away and sit naturally generally succeed best; but the reason given for it is not the true one. In the first place, hens that have proper nesting places under shelter rarely forsake them until cold weather is past. I never knew one of mine steal a nest until the warm weather had set in. If they try it in frost and east wind their eggs hatch, not better, but worse even than those under cover, in spite of damp ground and other supposed advantages, but in May or June nearly every egg produces a chick. Well, so they would if you had put them under a hen in your sitting house. The cause of it is not the damp ground, but the favourable conditions under which the eggs were fertilised and laid.

My opinion is that the vitality of eggs is not much affected by the east wind after they are laid, or during incubation; but that the mischief occurs before, to the birds themselves, during the time they are laying the eggs. I have no doubt that the cocks are seriously influenced by cold weather, and as a consequence the eggs are not properly fertilised. Added to this, the hens themselves are chilled and checked, so that, though they often continue to lay, their eggs are of very little use for hatching.

On the other hand, if eggs are laid during mild genial weather no amount of east wind during incubation will seriously affect them. My best brood this year was hatched from eggs set upon during three weeks of incessant bitter cold wind, with severe frost nearly every day. These eggs were laid during the mild weather we had in January. The nest was in a dry sheltered place, and no water was used in any way. My hens laid freely during the frost and cold winds in February, and beautiful-looking eggs they were; but I remarked at the time, "I question whether many of these eggs will hatch," and so it came to pass, not more than two in a dozen proving fertile. Those that were laid by hens in the most sheltered run hatched best. The run most exposed to the wind, though the hens there were with a vigorous cockerel, and my other birds with old cocks, produced the fewest good eggs.

I should much like to hear when other breeders obtained their best results this season. Considering the very mild January I quite expect that the eggs laid during that month

produced the best hatches, and that those who managed to have plenty of January eggs obtained also plenty of very early chickens hatched during the month of February. I quite expect to hear also that the broods in March and beginning of April were unusually small and weak, for the latter half of February and most of March was bitterly cold, and few eggs laid at that time would be fertile.

Now, if what I have advanced be true, what is the remedy? Sprinkling and damping the eggs during hatching is all nonsense. If the weather is very cold it will only give the hen more trouble to keep up the necessary temperature, and do more harm than good. It is not the eggs, but the fowls themselves that must be looked after. Do not let them stand about in the wind waiting for their breakfasts. Shelter your runs towards the north and east as well as you can. Provide for the hens a few extra dainties. Spice them up a bit, for it is the only time that spice will do them good. Favour your cocks especially with a little animal food, and as long as they are out keep them occupied; for I really think it would be better to shut them up most of the day if the run is exposed, than to allow them to stand about on one leg in the cold. If you have any eggs take them out warm from the nest, and do not leave them about, for if the weather is very severe they may be frozen. —R. W. Beachey.

CHICKEN FROM DOUBLE-SHELLED EGG—BREEDING PURE.

We have just successfully hatched a Houdan chicken which was enclosed by two distinct shells one within the other.

I should be glad to learn whether it is necessary for pure breeding to keep the breeds separate, except, of course, at such seasons as the eggs are required for hatching. The analogy of pigs, horses, dogs, would lead one to expect that constant separation is necessary.—E. L.

[We have seen before that which you note. We have, however, seen it only once, and our great surprise was how the chicken made its way through two strong shells, for they were fully formed and of an average thickness. When once hatched it became an ordinary chicken. These things have doubtless happened before, but they were not noticed. We have now preserved in spirit two perfect chickens, the result of a double-yolked egg, which was broken that the condition of it might be ascertained. Each is attached to a yolk. Both yolks and chickens are thoroughly distinct and perfect. We can recollect when these eggs were looked at with dislike and few would eat them. Even cook looked askew at them and would rather not use them, and the poultry woman asked to get rid of the hen that laid them. "There was something about her she didn't like, and she never roosted like the other fowls." "If you noticed, she had a cute look that didn't ought to belong to a fowl." The only offence of the poor hen was, she was subject to twins.

We believe there is no analogy between fowls and the animals you mention. All the Gallinaceæ are subject to season after their first laying. In some, as in all Game, they cannot be made to deviate from their appointed time for breeding. Indeed the only difference of sex would seem to be in plumage except during a few weeks of the year. The same is true of Ducks and Geese, and of all birds in a state of nature. The only deviation is, if a Pheasant or Partridge loses its first eggs it lays a second nestful. The Pewit or Lapwing that lays the delicious eggs known as Plovers' eggs will, if the eggs be taken three times, lay a fourth, but after that the season is past and she lays no more. In both cases it is curious that the desire to perpetuate its species, and thus fulfil the purpose for which it is sent, would seem to enable a bird to become fruitful at will, because if the first eggs had been left the Pewit would have sat on them and hatched them. A hen Pheasant running wild will lay fifteen or sometimes seventeen eggs and then sit, but if the eggs are taken away she will lay twenty-five or thirty. This fecundity is only during the season, and that extends over twelve weeks at the outside; sex then seems to disappear till the next breeding season. It is not exactly the same with poultry, because pullets lay at a certain age, but after they become hens they lay only in their season, and that is after the severe weather is past. For these reasons we do not think it necessary to keep fowls separate during the winter months. We have had many running together for years. We separate them two months before we wish to put the eggs under hens, and have never been deceived. For these reasons we do not think them subject to the same rules as the quadrupeds you mention.]

THE PRESENT HATCHING SEASON.

Having seen several letters in "our Journal" relating to the present hatching season, I thought—having received fourteen sittings of eggs from various parts of the country, and having kept a tabulated record of the result—that my experience would perhaps be interesting to my fellow fanciers. Herewith I enclose the form of particulars. I may say that, with the exception of three sittings, these eggs were purchased from well-known exhibitors at a cost of from 10*s.* 6*d.* to 25*s.* per dozen exclusive of carriage. The hens were set side by side upon the earthen floor of a house exclusively devoted to sitting hens, and where the temperature ranged from 45° to 65°. They were all taken off the nests at the same time by myself, supplied with food, water, and dust bath, and returned after an interval of from ten to twenty minutes according to the weather. The usual sprinkling and water bath was attended to.

I may add that the only ailment that I have had among the chicks has been diarrhœa, and that only to a slight extent. I feed about every two hours from 6.30 A.M. to 8 P.M. with chopped egg, bread and milk, bread and beer, grits, oatmeal, barleymeal, buckwheat, barley, and boiled liver. They have grass and vegetables *ad lib.*—N., *Ventnor, Isle of Wight.*

[We regret not being able to afford space for the very full tabular report of the proceedings and results, but we will give an epitome of them. There were 178 eggs, and these were divided into fourteen sittings. The chickens hatched were seventy-six, and thirty-six were dead in the shells. The other eggs were either broken, clear, or addled. Distance travelled and packing seem to have no material influence. Thus, thirteen Hamburghs' eggs travelled 296 miles, and changed trains five times, yet produced eight chickens. The same result exactly occurred with Houdan eggs after travelling fifty miles and three changes. Whether packed in paper and hay, or in oat husks, or in wadding, nine packages out of the fourteen came with eggs unbroken.—Eds.]

BEDLINGTON SHOW OF POULTRY, &c.

The eleventh annual Show was held at this plucky colliery village on the 17th and 18th inst. The weather was very fine and warm, and the birds protected by two excellent marquees, which while being a perfect protection admitted the light in a perfect manner. There were some empty pens as might be expected, the birds arriving late; and in Pigeons almost one-half the birds were not in the pens, Mr. Van der Meersch's being among the lot.

Cochins were good, the cup for the first four classes going to an exceedingly rich pair of Buffs, and in the next class the section cup for five classes was awarded to a grand pen of *Spanish*, the second being also a grand pen. *Polish* were all noticed. First Silvers, and the rest Gold. The third and highly-commended pens had capital pullets, but poor cocks as compared with the winners. *Game* had six classes and had good entries. In single cocks were eighteen entries, almost every pen being good, the cup for Game being awarded to a Duckwing cock which was grand in every particular second was a Brown Red, good in style and colour but a little scant in tail. The best single hen was a Black Red, one of the best in fact that has been out of late; second was a Brown Red, and third a Duckwing. Black and other Reds were, first a hard and close-feathered pair of Brown Reds; second a pair of Champion Black Reds, not, however, in the highest order; and third good Brown Reds. Duckwings were not a good class, only the first-prize pen being of any note. *Hamburghs* had four classes, and these were very even throughout, the cup going to a neat pen of Gold-spangles. Poultry, any other, were, first Black Hamburghs, and second and third Houdans. *Bantams* were a smart section, the birds being well shown and mostly in capital feather. Single cocks were good, except that some of the best were a little heavy in tail. Hens a fair lot, the first winner very good, second a Brown Red. In Red Game Bantams, pairs, the first, the cup was awarded to Black Reds, good in style and general quality, but the hen a little white in ear, but they seemed to be shown in a most natural state; second and third of that colour were very good. In the next class Duckwings were first, and needed only soap and water to have ensured the cup; second were very smart Piles, as also the third. The latter, however, were a little too light on the wing ends. Black Bantams were very good, but some of them a little overshown. Only the first in Aylesbury *Ducks* were good, but the Rouens were a good class; and in the Variety class first were Pintails and second Widgeons.

The cottagers' classes were a surprise to us, class after class proving good, the Cochins being about the best of such classes we have ever seen in the north of England, many birds proving quite perfect, and in almost the same degree these remarks will apply to the Bantams.

Pigeons, as before stated, were pretty numerous, and also as a rule well placed, the cup going to a capital Carrier cock. Second was a Dun cock, and pen 211 being very good but rough and not well shown. The first Short-face was an Almond cock, good in head but a little muddy in colour; second was a good Black Mottle. In Long-faces first and second were Black Mottles, both good; although we were surprised pen 215, an Almond, did not receive one prize—but perhaps this was right. Pouters were a grand class; the first was a Blue and second a White cock, many other birds being justly noticed. Two Black-pied

hens were really good, pens 239 and 242. Dragoons were not to our mind, being mostly of the broad-shaped-headed kind, and few were noticed. Nuns were good, but many pens were empty. In Owls first was a foreign White, and second a Silver English. Fantails poor, and Magpies only moderate, if we except the first-prize Black. In Antwerps Mr. Yardley's well-known Short-faced Silver was first, and a good Silver Medium second. The Selling class was poor.

CAGE BIRDS were but few in number but a very select lot, the winner in each class being particularly good of its kind, the first in Dutch being a grand showy specimen. Mules showed the great care exercised in their breeding, some almost clear birds and many even-marked birds turning up. The Goldfinch class was particularly good, in fact it is seldom we find any class to surpass them.

In consequence of the wording of the schedule in the class for singing birds it was ruled by a knot of the Committee that Canaries were excluded, and the consequence was that birds not strictly known as song birds were awarded the prizes—viz., first a Bullfinch and second a Snow Bunting; and we think it would be much better in future if this class be expunged and one for British birds be substituted, then exhibitors will not be misled in making their entries.

RABBITS were but poor if we except the first-prize Tortoise-shell Lop buck, which was a very good specimen.

DORKINGS.—1, J. Carr, Whitby. 2, W. Swann, West Sleekburn.

COCHINS.—*Buff or Cinnamon.*—Cup, G. H. Procter, Durham. 2, W. Swann. *hc*, E. Winwood, Worcester. *c*, Urwin & Ibeston, Whitby. *Any other variety.*—1, G. H. Procter.

BRAHMA POOTRAS.—1, W. Swan. 2, C. Cruddace, Seaton Delaval.

SPANISH.—Cup and 1, H. Beldon, Goitstock. 2, J. Oliver, Burradon Colliery. 3, R. Simm, Bedlington.

POLISH.—1 and 2, H. Beldon. 3, R. Parsons. *vhc*, H. A. Clark, Aspatria, Carlisle.

BARNDOOR FOWLS.—*Crossbred*—1, G. Robinson, North Frodingham. 2, J. W. Lawson. 3, J. Ford, High Ewart Hill. *c*, J. Merriman, Bedlington; J. Short, Wooler.

GAME.—*Any variety.*—*Cock.*—Cup and 1, J. Young, Bebside Colliery. 2, J. W. Brockbank, Kirkseaton. 3, E. Aykroyd, Eccleshill, Leeds. *vhc*, W. Younghusband, Darlington; Miss M. J. Nelson, Cockshaw, Hexham. *hc*, J. Howey, Longhirst Colliery; T. E. Satterthwaite, Castle Howard, York; G. Latimer, Washington, Durham; G. Bennett, Dinnington Colliery. *c*, J. JUDGES.—*Poultry, Rabbits, and Cage Birds:* E. Hatton, Pudsey. *Pigeons:* T. J. Charlton, Bradford.

SUNDERLAND POULTRY SHOW.

WITH so many enthusiastic fanciers it has long been matter of surprise to us that an annual open show has not been held at this place, but we think this first attempt has so far succeeded as to ensure its annual occurrence, for the first day being exceeding fine the gate money was something handsome, although the second day proved somewhat showery. It is, however, to be regretted that some other time was not chosen, for two shows in the north of England held at the same time cannot be expected to do as well as if held separately, and Bedlington having established a claim to the Whitsuntide holiday by eleven shows ought to have been allowed that time unmolested. The entries were 199, those of Bedlington being 204. The show field was a little too far from the principal parts of the town, but an excellent marquee was provided, and Fothergill's pens were used with good effect.

Dorkings were first, and on our entering we were surprised to find Mr. Widdas's grand pen left out, but we found they were too late for competition. The winners only were good. The winning pens of *Spanish* were very good, and we were particularly struck with the quality of the cock in the second-prize pen. *Cochins* good in Buffs, Mr. Proctor winning, as also in the next class with a neat pen of White; Partridge winning second. Dark *Brahmas* were a fair class, more numerous than some of the others. In *Game* (Reds) the first were Mr. Mason's well-known old, very old, pen of Black Reds. Brown Reds were second, but the class was not good. Pen 50, Brown Reds, were, however, very good, though young. In Game, Any other, Duckwings won, both good, the cock in the first especially so. Pen 60, Piles, were good but out of feather. In single cocks we are sorry we could not agree with the first award; this was a Black Red of enormous size, in our opinion quite 9 lbs. weight, and very coarse. Such a bird should not be allowed a place. The second was a Brown Red, well placed, but a little out of condition. Pen 63 (Morgan) we should have placed first, this bird being faultless, and by far the best Game fowl in the Show. Hens were very poor. In *Hamburghs*, as in some other classes, many pens were empty, but the winners were very good throughout, the cup going to Gold-spangles. *Malays* were a good class, and may be taken as a guarantee of what may be expected if classes were provided generally for this handsome variety of bird. In the Variety class first were Silver Polands and second Black Hamburghs. *Bantams* were the section of the Show, and being the figurehead of the fancy in this locality we were not surprised to find so good a lot; but before proceeding to criticise the awards in this section it is but fair to state that in some parts of the tent the rain had penetrated, and nothing tends so much to alter and improve the style of a Game Bantam, so that seen under other circumstances our opinions might have been quite different. In Black or Brown Reds we liked Mr. Hall's highly commended pen 118 in preference to any other, although the

first were a good pen, as also the second. The class was of rare quality, and many more notices might well have been made. Duckwings won both prizes, although there were some most perfect Piles. In the first-prize pen the cock was a gem, but the hen a wretch indeed; more, however, for want of bloom than anything else. Second was a fair pen. To both of the above we preferred Mr. Nelson's Duckwings and Messrs. Bellingham & Gill's Piles. Black Bantams were good and in fine order. Bantam cocks were the best class in the Show, almost all being worthy of notice, and we could not envy the Judge's task here. Black Reds were the winners. Hens were poor, and the *Ducks* of both kinds of moderate quality.

Dorkings.—1, D. Gellatly, Meigle. 2, Henderson & Wardle, Bornopfield, Durham. *c*, J. White, Northallerton.

Spanish.—1, H. Beldon, Goitstock, Bingley. 2, R. Shield, Swalwell. *hc*, W. McIntyre, Ochilhee.

Cochins.—*Cinnamon or Buff.*—Cup, 1, and 2, G. H. Proctor, Durham. *hc*, C. Turner, Norton, Stockton; J. Hine, Kendal. *Any other colour.*—1, G. H. Proctor. 2, W. Newbegin, Newcastle.

Brahmas.—*Dark.*—1, T. F. Ansdell, St. Helen's. 2, W. Whiteley, Sheffield. *hc*, C. Venables, Sheraton, Castle Eden; Lady A. B. Peirse, Bedale Hall, Bedale; T. F. Ansdell. *Light.*—1, W. Whiteley. 2, S. H. Lloyd, Maghull.

Game.—*Black or Brown Reds.*—Cup and 1, J. Mason, St. John's, Worcester. 2, J. Robson, Bishop Auckland. *vhc*, Henderson & Wardle. *hc*, Miss M. J. Nelson, Cockshaw, Hexham; J. Dixon, Monkwearmouth. *Any other variety.*—1, J. A. & H. H. Staveley, Driffield. 2, J. Mason. *hc*, J. Robson; T. Young, Bebside, Morpeth; E. Winwood, Worcester; R. Walker, Gomersal, Leeds.

Game.—*Any variety.—Cock.*—1, J. Harrell, Bishopwearmouth. 2, A. Sugden, Cleckheaton. *hc*, C. E. Morgan, Bishop Auckland; Miss M. J. Nelson. *Hen.*—1, C. E. Morgan. 2, T. Young.

Hamburghs.—*Golden-spangled.*—Cup and 1, H. Beldon. 2, T. P. Carver, Langthorpe, Boroughbridge. *Silver-spangled.*—1, H. Beldon. 2, G. Alderson, West Hartlepool.

Hamburghs.—*Golden-pencilled.*—1, T. P. Carver. 2, H. Beldon. *c*, J. N. Lawson, Ryhope. *Silver-pencilled.*—1, H. Beldon. 2, J. T. Gilbert, Bishopwearmouth. *hc*, Dr. Davidson, Bishopwearmouth.

Malays.—1, Rev. A. G. Brooke, Shrawardine Rectory, Shrewsbury. 2, R. Hawkins, Seaham. *hc*, G. Burnell, Rugeby.

Any other Variety.—1, H. Beldon. 2, H. A. Clark, Aspatria. *vhc*, G. W. Grainger, Bishopwearmouth; J. T. Proud, Bishop Auckland. *hc*, W. Coulthard, Southwick; T. P. Carver; C. Venables; Bridgwater & Yoxall, West Bromwich; A. Buglass, Durham.

Game Bantams.—*Black or Brown Red.*—Cup and 1, G. Hall. 2, T. Stansfield, Millfield. *hc*, G. Hall, Kendal; F. Holt; Miss M. J. Nelson; J. Ferry, Cowpen, Morpeth. *Any other colour.*—1, D. Hunter, Sunderland. 2, T. Mallen, Sunderland. *hc*, Miss M. J. Nelson; Bellingham & Gill, Burnley; T. Stansfield.

Bantams.—*Black and White Rosecombs.*—1, J. Mayo, Gloucester. 2, H. Beldon. *hc*, Milner & Beanland, Keighley; Miss M. B. Yeoll, Bishopwearmouth; R. H. Ashton, Manchester. *Any other variety.*—1, T. B. Carver. 2, R. A. Boissier, Peasharst.

Bantams.—*Any variety.—Cock.*—Cup and 1, Miss M. J. Nelson. 2, A. Sugden. *hc*, W. Newbegin; R. Brownlie, Townsend; H. H. Thompson, Bishopwearmouth (2); D. Hunter, Sunderland. *c*, G. Hall. *Hen.*—1, T. Clark, Sunderland. 2, T. Stansfield. *hc*, G. Alderson; Miss M. J. Nelson; J. Barlow, Monkwearmouth; G. Hall; A. Sugden.

Ducks.—*Aylesbury.*—1, R. Roddom, Hetton-le-Hole. 2, F. E. Gibson, Middleton-in-Teesdale. *Rouen.*—1, W. H. Young, Driffield. 2, Miss M. J. Nelson. *Any other variety.*—1 and 2, J. Johnson, Sunderland.

Selling Class.—1, J. Hine. 2, J. Robson. *hc*, W. Allon; J. N. Lawson.

The Judge was James Dixon, Esq., North Park, Bradford.

"A SWARM OF BEES IN MAY IS ——."

While hay is being sold at £8 per ton the most advanced and pronounced apiarians dare not finish the above sentence or make the assertion; still I, and many others, venture to assert that bee-keeping is both an easy and profitable occupation. To both rich and poor it is, or may be, a self-rewarding recreation. I speak from experience in saying that it is a pleasing and upholding thing for a son of toil to know that while work and weather combine to cover his forehead with perspiration, his industrious bees are working harder than he and gathering together the worth of a week's wages in one day.

Aforetime I have had great pleasure in writing for the encouragement and benefit of working men; and for their encouragement I will here state that from 1870 to 1874 my profits from bee-keeping, after deducting all expenses, amount to £220. The first three years of this period were considered unfavourable for bees. 1873 was the most unfavourable year for them I ever experienced; and last year, though unfavourable till the end of May, became favourable in June, and continued so till the end of the season. These facts and figures are named here to help young apiarians to look hopefully to the future.

Bee-keeping is an easy and profitable pastime. Where shall we find anything living that requires less attention than bees? They clean and furnish their own houses, and in ordinary seasons store up more honey than they need—honey enough for the market or their owner's use. A few hives in a garden indicate recreation, not toil—profit, not expense. What less costly to keep than bees? With sugar at 3*d.* per lb. (some is sold in Manchester at 2½*d.* per lb. good enough for bees) bee-keeping is not a losing game even in unfavourable seasons. The expense of feeding during unpropitious weather is as nothing now compared to what it was fifty years ago, when sugar cost from 9*d.* to 1*s.* a-pound. Four or five shillings' worth of sugar given as syrup to a swarm will enable it to fill, or nearly fill, its hive with combs and store up food enough for the winter months, thus making a stock hive worth 30*s.*

Once in possession bees may be managed on any system their owner likes. On the multiplying principle one will become three, and ten will increase to thirty in one season. Swarms from small hives under good management or kindly treatment will fill larger hives. In this way stocks increase not only in number but in value. With good stocks of bees and a little knowledge of them progress and profit will be made. To working men bee-keeping is more than a hobby; it is an aid to breadwinning in his family—a perennial source of income.

Bees may be managed on the restrictive or non-swarming system. An eagle may be chained to a block of wood or stone, and a vine may be grown in a pot; but all this is restrictive and unnatural. Bees have powers of multiplication, expansion, and growth that may be restricted to narrow limits, and there kept in a state of dwarf-hood. But on any system of management there is but little work or attention required. Where bees are farmed to the utmost extent, and taken from one locality to another, there is an expense of both time and money.

"Where shall we find a market for our honey?" is a cry that comes frequently to us from the country, and from bee-keepers in all positions of society. This cry indicates skill and tact in apiculture, and it is very pleasing to us to know that hundreds of bee-keepers are now pocketing the proceeds of very successful management. In country places there is a difficulty in finding a market for all the honey gathered in a good season. But so far as I know, all country bee-keepers do in time find a market and demand for their produce. I am frequently hailed by buyers in Scotland, but last year I was hailed by a dealer in Chelsea market, London, who wanted all I had. Fortunately I did not send any to him, afterwards learning that he is one of a "long firm," who obtained honey from some bee-keepers in a neighbouring county without making payment.—A. Pettigrew.

CEMENT FOR GUIDE COMBS.

When using bar-frame hives or supers it becomes a necessity in order to secure good straight combs to furnish some guide for the bees to start their foundations on—a thin strip of comb, Neighbour's impressed wax sheets, or simply a narrow strip of molten wax run down the centre of the bar; either of these plans answers, but how to fix the wax guide to the wood has always been a trouble. Various smelters have been invented, but they are troublesome from the liability of the hot wax to congeal before the operation is successfully completed. This led me to set my wits to work and bring my chemical knowledge into use to discover some solvent for wax which would make a good cement; after trying several things, the result was the "liquid wax" I exhibited at the British Bee-keepers' Association's Conversazione, and which answers the purpose admirably, not only for a cement, but to form a wax guide itself when desired. It is made thus: take of wax cut up small 1 oz., put it into a wide-mouthed stoppered bottle, and add to it 1 oz. of benzine or benzole, not benzoline; in twenty-four hours it will be found to be a paste which may be rubbed smooth on a slab with a pliant table-knife. The benzole has the well-known gassy smell, but being highly volatile passes completely away after a few hours' exposure to the air. In cementing on the strip of guide comb use the cement as a bricklayer does mortar in laying a brick, pressing the comb into it, or a ridge of the cement may be placed on the bar. I have tried it both ways, and find the bees have not the slightest repugnance to it, showing that no trace of the benzine is left.—John Hunter, *Eaton Rise, Ealing.*

DRIVING BEES FROM SUPERS.

As your correspondent, "W. G.," is not alone in finding it rather difficult to rid a super of honeycomb of its bees, a few words here may help others as well as himself. On taking a super from a hive the first thing to be done is to sever it from the hive by drawing a fine wire between the two, then raising the super about three-eighths of an inch by wedges to allow the bees to lick the honey clean from the broken cells. They generally do this in less than an hour. As soon as it is done, smoke from fustian or corduroy rags should be blown into the super by the top hole in abundance. This smoke makes the bees run from the super into the bottom hive.

This easy and simple mode answers well in warm weather, for often not a bee remains behind. In colder weather bees are not so easily dislodged. On two or three occasions we have had to use a small bit of brimstone rag amongst the fustian rags ere we could make the bees leave the supers. The smallest taste or sniff of sulphur fumes terrifies bees and makes them run for their lives. But the greatest precaution is necessary in using it, for if given freely, or even in moderate doses, it would kill the bees amongst the combs; and dead bees between the combs of a super could not be taken out without injuring the combs. Sulphur should not be used by inexperienced people. If a dozen or two of bees remain amongst the combs after the smoke of fustian rags has been applied, we take the super off for a few minutes and cover it with a cloth, then carry it to the door of the hive in which the noise of the bees attracts and withdraws the bees from the super. Once make them run, bees are like a flock of sheep or a pack of hounds in following one another. In running from super to hive the bees make a

sound as they do in swarming, and this sound or noise soon empties the super of every bee. All this may be done in a very short time, and I think there is no better mode of ridding supers of bees than the above.

There are instruments invented and sold for this work, but I have never required anything of the kind. Sometimes we have not had time to contend with a few stubborn bees in the combs of supers, and have carried the supers into a cellar and placed them at a distance from the window, which was opened to let the bees fly out and go home. Sometimes we have placed the supers on their crowns and covered them with a bit of flannel or woollen cloth. As soon as the combs became cold the bees left them and settled on the woollen cloth. In resorting to the cellar the process is slower, and therefore the danger of having the combs spotted by the bees is greater.—A. PETTIGREW.

THE CARR-STEWARTON HIVE.

THERE are this year very many modifications of bar-frame hives presented to our notice and offered for sale at prices ranging between 10*s.* and 50*s.* per hive. The modifications in most of them are so slight and unobservable that it takes an expert to discover them and tell us what they are for. But the Carr-Stewarton hive is a distinct combination of two hives and two principles very dissimilar.

The principle of the Stewarton hive is united to that of the common bar-frame hive. The Carr-Stewarton hive is a three-decker, or three-storeyed, and is managed on the Stewarton principle. The hive I saw is neatly made and pleasing to the eye—far more symmetrical than most bar-framers. When all its parts are put together it stands about 17 inches high, and is 13 inches wide inside measure. In each of the three compartments there are windows all round, and wooden blinds or shutters hung on hinges and neatly fitting. It is quite a fancy hive, and likely to please ladies and amateurs. Its price complete is about £2 without the cover. The hive I saw has a framework of wood very neatly filled with straw; the materials of this hive are therefore unobjectionable, but some of the same kind of hives are, I believe, made wholly of wood. The hive in question contains two kitchens and a pantry, or two stock boxes and a honey box. The stock boxes are 5½ inches deep or thereabouts, and the stock box 4 inches deep.

As the inventor doubtless meant it for a honey hive, he may not be offended if I look at it from a practical point of view. When a box or compartment of a hive is only 6 inches deep, with frames inside, the combs in the frames must be very shallow—too shallow for vigorous growth and prosperity, and the bees in the bottom box too near the door when they first begin to breed in spring. Shallow hives are not the best for breeding purposes. Hives 10 or 15 inches deep are much better for breeding in than those that measure 5 or 6 inches only. I am of opinion that for great results in honey or honeycomb this Carr-Stewarton hive is too complicated and small. For honey-gathering I should prefer a hive with one compartment only, or "stock box," one-third larger than both stock boxes in this hive; but the appearance and the workmanship of the Carr-Stewarton are admirable.—A. PETTIGREW.

OUR LETTER BOX.

TUMOUR IN HEN'S CROP (*W. H.*).—Tumours such as you describe usually arise from the general unhealthiness of the fowl. As we know nothing of either the management or feeding you adopt, we cannot advise you.

REARING YOUNG TURKEYS AND GUINEA FOWLS (*David Drake*).—Young Turkeys require to be fed almost like young Pheasants. They should have at first bread and milk, some chopped egg, mixed ground oats or ground barley, in which onion tops may be chopped very fine and mixed. In cold and trying weather they may have some beer to drink, and some bread soaked in ale to eat. They also like curd made with good milk, and they thrive on it. One most important thing is that the hen should be kept in confinement, or she will drag the poults through the dewy grass, and lose half of them. The hen should be put during the day where she has the most sun; and when the poults are three weeks old she may be let out, but only when the grass is perfectly dry. You may treat Guinea Fowls the same; but they may be let out earlier with the hen, say at a fortnight's end, but that must be when it is dry.

SEED FOR BULLFINCH (*Subscriber*).—Summer rape seed crushed or steeped now and then in water all night, and afterwards dried in a cloth. It is more suitable than canary seed. Occasionally give a little hempseed, also a little crushed plain biscuit and green food, such as watercress or small salad. No sweets. The buds from the ash, oak, or pear trees may be given. A part vegetable diet will tend to rectify the bird's system, and cure it of the hoarseness. The bird's stomach is evidently out of order.

POSTPONING HIVING A SWARM (*J. H. D.*).—Shading a swarm as it hangs on a tree does not prevent the bees from seeking a more comfortable home, and one in which combs can be built; and it does not prevent them from going to one as soon as it is found. You should have hived your swarm as soon as possible after it settled on the tree. In about ten days after the hive swarmed you may have a second swarm. For three days and nights before a second swarm issues the young queens may be heard piping.

PREVENTING SECOND SWARMS (*A. S.*).—It is an easy thing to prevent hives from casting off second swarms. Young queens generally come to perfection in about ten days after the old queen has left the hive with the first swarm. As soon as piping commences or one young queen is hatched, all the royal cells may be cut out of the hive. When this is done no after-swarming will take place. If all the royal cells containing queens cannot be seen or reached the bees of the hive could be wholly driven out in a few minutes, and thus the bee-master can do what he likes. But the simple operation of driving the bees out generally sets at liberty the confined princesses. They are, in a sense, prisoners in cells, and when their keepers and attendants are alarmed and scared by the drumming and tumult of the hive they bolt out of their cells. If all the queens thus bolt out no after-swarming will take place, even if all the queens be thrown back with the bees into their hive. If any of the princesses remain in their cells they could be cut out before the bees are cast back.

FEEBLE HIVE (*Amateur*).—We much fear that your feeble hive is not worth the trouble and expense of nursing. It would be far better to fumigate the few remaining bees and obtain a new swarm to put in their place. They would pay you in the end far better. It is quite clear from your account that they have lost their queen through old age or some accident. Before you put a swarm into the hive examine the condition of the comb, and cut out any of it that looks defective or moth-eaten.

REMARKS.

19th.—Sometimes very bright, sometimes dark; loud thunder and vivid lightning commencing at 2.10, but it was neither near nor long-continued; very bright night.

20th.—Fair but overcast in morning, rain at intervals, and much colder towards evening.

21st.—Fine morning, showery afternoon, fine evening and night.

22nd.—Dull morning, fine at noon, showery afternoon, fine evening; but the wind high all day.

23rd.—Very fine and pleasant all day, rather cool at night.

24th.—Bright pleasant day throughout.

25th.—Another fine, pleasant, but not hot day.

A pleasant spring week; temperature a little lower than in the preceding week.—G. J. SYMONS.

COVENT GARDEN MARKET.—MAY 26.

THERE is no particular change in the condition of the markets since last report, supply and demand being about equal. The only deficiency worth noting are the usual good samples of Peaches and Nectarines that are to be seen at this season. English Pines have been in better request, but heavy consignments from St. Michael's *vid* Lisbon are in the river, and will be sold in a few days. Potato trade heavy; large consignments from Jersey and Guernsey on hand.

From observations taken near London during forty-three years, the average day temperature of the week is 70 0°; and its night temperature 46 2°.

THINNING FLOWERS AND FRUITS.

BY reducing the number of fruits borne by a plant to a reasonable limit we thereby gain size and quality; but although this is believed and acted on to a certain extent by all fruit-growers of any pretensions, it is too often deferred so long as to make it of little or no use. If it is once admitted that thinning is beneficial it would certainly be more consistent with reason to thin as early as possible. Rose-growers and Chrysanthemum-growers for exhibition need no spurring-up to make them thin their flowers betimes; they know full well that if they want fine specimen flowers they must thin early, so that the good things which Mother Earth supplies for nourishment may not be too much subdivided. If this is the case with flowers, the greater part of which are abortive, how much more must it be so with the flowers of fruits, which must of necessity be fertilised before they can swell.

Now, I have a very strong impression that this act of fertilisation is the hardest work a fruit tree has to do. It generally takes place before the tree has perfect root and leaf action, and often during the most unfavourable weather. An abundant bloom on fruit trees is an event I have a particular dislike for, it so very often produces barren results. Every flower must have a certain amount of supply from the plant to insure its fertilisation, and the supply we know is limited. A large tree might be able to perfect with ease a thousand flowers—an addition of an extra five hundred would be too much of a strain on it. Well, then, supposing instead of a thousand there are many thousands, perhaps millions, there must be a tremendous struggle going on for the mastery—not a civil war, but a sort of all-round fight, and the result is frequently the utter annihilation of all the combatants.

Thinning the flowers before expansion would have prevented this; it cannot be done with large trees, but there is no difficulty about small trees, such as are usually grown in gardens, and it is these small garden trees which fall oftener than the more natural-grown orchard trees do, and for this reason—they are pinched time after time during the summer and induced to make fruit buds where, if left to themselves, wood buds only would be produced, and the consequence is a superabundance of fruit buds.

I have nothing particular to say against this system of producing miniature fruit trees; they are very handsome and very interesting, but if carried to the extreme the form of the tree and the beauty of the flower is often all one has for the trouble. To have fruit we must be prepared to sacrifice a little of the beauty of the flowers either by pulling them off singly before they expand, or, what is better, by pruning the fruit spurs in autumn, as soon as growth is finished, to a reasonable number.

With regard to stone fruits, I have proved over and over again the utter fallacy of deferring the final thinning till after stoning, and I am pleased to see that Mr. Douglas at every favourable opportunity advances views on this subject in harmony with my own. Thin immediately swelling commences, leaving a few extra fruits in case some should be deformed from the flowers having been injured. Do not leave the fruits till they grow to the size of marbles and then say you will try this system, it will be too late then. When practicable thin partially before the flowers expand; half the number of flowers are so placed that they will be of no use if they set, and it must be folly to leave these at least to the detriment of those which are well placed.

One of the evils of overcropping is that it prevents leaf growth. You may see a Peach tree or a Vine indoors receiving the best of attention in every other respect, but is too heavily cropped, the growth of which at certain times when there is a little extra strain on the plant—say at the time of flowering or stoning—is completely at a standstill. When this is the case it ought to be taken as a warning that the work the plant has to do is too much for it. Without continual healthy leaf action you cannot have fruit either large or of good quality. Probably the cause of fruit falling at the stoning period is owing to this stagnation of growth of foliage produced by overcropping. Certain it is that moderately cropped trees, if healthy, do not drop their fruit.

Thinning ought not to stop at stone fruits. Nothing pays for thinning better than the Pear; and let those who will sing the praises of late Peaches, they are welcome to sing about them and eat them too, as long as I can lay hold of a Doyenné du Comice or a Beurré Superfin Pear.—William Taylor.

CUT-BACK ROSES.

I think Mr. Reynolds Hole, one of the greatest authorities on all Rose matters, has laid down a dictum in his book on Roses that to grow blooms fit for exhibition they must be grown from the bud on the Briar. In other words, only maiden Briar blooms are fit for exhibition. Now I think this axiom has been over and over again proved to be false, and I should like to ventilate in your columns this question—Is not a cut-back plant either a Manetti or a Briar Rose equal to the maiden blooms of the Briar if cultivated with the same care? My own opinion is most decidedly yes, and I can produce most excellent evidence that this opinion is by no means a rash one. I will ask any of your readers who saw them to recall to their minds the Roses which Mr. Baker of Heavitree showed at the Crystal Palace, Hereford, and Exeter in the year 1871. At Exeter he showed forty-eight Roses in the open class for a £10 cup, and beat Mr. Keynes of Salisbury. Now he was here showing entirely from cut-back Manetti Roses, while Mr. Keynes were all maiden blooms. At the Crystal Palace, and at Hereford, he was first in every amateur class, as also in the open class for twelve blooms of the same Rose. He had not that year a maiden plant in his possession. This year he will almost entirely be showing from cut-back Manettis, and I prophesy that he will show such

blooms as have never been seen since 1871 on any amateur's stands.

Let anyone, then, who thinks that to grow prize blooms they must bud their own stocks, look out for his Roses at the shows this year, and compare them with the nurserymen's maidens. The year I won two firsts in the only classes I showed at the Crystal Palace was 1872, when I did not possess a maiden plant, and since I have budded my own I do not think my blooms have been so good.

I am not writing this in the interests of nurserymen, but simply to open a question which I think will interest all lovers of the Rose. Indeed I believe the nurserymen (though greatly against their interests) will almost to a man condemn my proposition. But why will they do this? Simply because they have nothing to do with cut-back plants; they know very little of them; their object is to sell all their stock year by year, and they will at the close of a season even sell at a sacrifice rather than not clear their ground. Mr. Walters of Exeter at the close of the season sells splendid Manetti plants at 5*s.* a dozen. The nurserymen then show entirely from maiden plants, and they speak according to their experience. But let anyone walk down a line of Roses at one of our nurseries in June or July, and see what a lot of coarse bad blooms there is, redeemed only by a few magnificent blooms here and there. I venture to say that he will see far more bad blooms there than he will in his own or any other amateur's carefully tended rosery.

Then the advantages of growing cut-backs are numerous. In the first place you are doing good to some of the best fellows that ever walked, I mean the large Rose nurserymen. You keep their trade going like a house on fire, and doing good to others should be one great principle in all that appertains to the queen of flowers. Secondly, you save space and time to an enormous extent. Let anyone look at the space, say, that a thousand or two thousand Briars take up in a nursery, and then look at the time those take before they give you blooms. They are planted in November, and it is not till June or July in the second year that your Briars become Roses. Thirdly, then the failures. These represent in amateur collections a very large per-centage of the whole; while, on the other hand, one of our large nurserymen rarely sends out any but strong plants, which nearly always do well. Fourthly, then there is the weary labour of budding, of tying, untying, rubbing out the wild growth, tying up the young growing shoot, the expense of the bast, the disappointment of some of your choicest Roses being destroyed by the wind in spite of all your efforts. Lastly, the late development of these maiden plants. The Crystal Palace fixture is often too early for the maidens, never for the cut-backs.

These and many other reasons cause me to recommend cut-backs to all whose space is the least limited, who want quick returns for their money and care, and who want to compete at the early shows. If you have space and unlimited money at command, then go in for both kinds so as to secure succession; but if you are obliged to choose between one or the other, grow cut-backs.

I am writing this in the hope of its eliciting discussion and any amount of contradiction. "I likes to be despised" in Rose matters, so long as my despisers know anything about the matter; but what I like much better is to see any subject connected with the Rose discussed in the columns of our Journal, which I consider is the greatest friend that the queen of flowers possesses. I know that there are a vast number of your readers who look out week after week for articles or letters on Rose culture, and that the more men read the more they cultivate Roses.—John B. M. Camm.

ROYAL HORTICULTURAL SOCIETY.

June 2nd.

Considering all the surrounding circumstances—the real impediments, the hard sayings, the failures of the minor shows, the unsympathetic tone existing, it is a matter of surprise that there is a show at all to report. "Great" only in name was the general prognostic of the principal display of the season, and it was never expected that for quality or extent the exhibition would be worthy of its designation as the "Great Summer Exhibition of the Royal Horticultural Society." Still the display is a good one, the quality of the plants sent being more noticeable than the quantity. They were staged in the two conservatory corridors, and were the objects of generally favourable criticism. The plants exhibited for Mr. Bull's prizes were extensive and valuable, and as being the introduction of one firm in the course of three years speak volumes for English commercial enterprise. Referring to the classes we find several empty, but those occupied generally contained good plants.

In the class for twelve Orchids Mr. Douglas staged bright, healthy, well-bloomed plants of Cattleya Warneri, Dendrobiums Farmeri, Bensoniæ, and nobile; Lælia purpurata, Cypripedium spectabile, Phalænopsis grandiflora, Masdevallia Harryana, and Oncidiums papilio, ampliatum major, and phymatochilum. The first prize was awarded to him.

Mr. Douglas also exhibited in the open class, and had the premier award. His group consisted of Orchis foliosa, exceptionally fine; Dendrobium thrysiflorum, noble spike; Masdevallia Whitbourniana, very bright; Cypripediums spectabile and barbatum, Lælia purpurata, &c. Both these were clean bright groups.

For twelve new plants, Orchids excluded, Mr. Bull had Phyllotænium Lindeni in fine form, capital examples of Pritchardia grandis, and Kentia Moorei, Anthurium crystallinum, Dracænas, Crotons, and the beautiful Fern Pleocnemia Leuzeana. Mr. Williams had two noble weeping tree Ferns, Cyathea Burkei and Alsophila Williamsii, a large Ficus Parcellii, Dracænas, Crotons, &c.

For eight greenhouse Azaleas (nurserymen), Messrs. J. Ivery and Son, Dorking, staged densely-bloomed pyramids, 4 feet high, of Flag of Truce, Reine des Pays Bas, Chelsoni, Forget-me-not, Tricolor, Charles Encke, Oracle, and Madame de Cannaert d'Hamale. This was the only collection in the class, and was worthy of the first prize awarded.

For six Azaleas (amateurs), Mr. Ratty, gardener to R. Thornton, Esq., Sydenham Hill, was the only exhibitor with the same immense pyramids which he exhibited at the Palace. Criterion is fully 6 feet in diameter at the base; Burlingtonia, a beautiful deep pink, is a globe 6 feet over; while Extranei, Iveryana, and Gledstanesi are considerably larger. They had the first prize.

For fifteen Azaleas (open), the first prize was awarded to Messrs. Ivery & Son, who had plants varying from 18 inches to 3 feet in diameter, and closely bloomed. The most striking were Mars, Iveryana, Duchesse Adelaide de Nassau, Surprise, Grand Crimson, very beautiful; Fanny Ivery, and a seedling with a singular mixture of white and scarlet blooms. This was a well-grown and highly attractive group of plants.

For twenty fine-foliaged plants in pots not exceeding 12 inches in diameter Mr. Bull exhibited a bright and beautiful group of medium-sized plants, of which Paulinia thalictrifolia, Croton Weismani, Dracænas regina and Goldieana, and Pandanus Veitchii were remarkably well grown. The Palms also were good. Smaller plants were staged by Mr. Wills, of which Sphærogyne latifolia, Aralia fastigiata, Zamia Lehmanni, Xylophylla latifolia, Dieffenbachia nobilis, and Terminalia elegans were very ornamental. Mr. Aldous also exhibited, and had the third place. For nine fine-foliaged plants (nurserymen), Mr. Wills exhibited a large Pandanus Veitchii, Phormium tenax variegatum, Encephalartos villosus, Dieffenbachia, Dracænas, &c.—a very good group. Mr. Aldous competed, but his group was deficient in bright colours.

For twelve Palms in 8-inch pots (open), Mr. Bull exhibited bright glossy plants, of which Verschaffeltias melanochætes and splendida, Dæmonorops palembanicus, Cocos Weddelliana, and Hyophorbe Verschaffelti were the most noticeable. Mr. Wimsett, however, was first with larger but not such choice and attractive plants. In the class for six Palms (nurserymen), Mr. Wills had large plants but deficient in lustre, but merited the first prize which was awarded them. For six Crotons (open), really excellent plants were staged by Mr. Bull of Weismanni, Youngii, volutum, undulatum, spirale, and majesticum. These were fine in health and good in colour. Twelve Dracænas and Cordylines (open), Mr. Bull had healthy and well-coloured plants in 12-inch pots, varying from 2 to 5 feet in height, of D. Baptistii, Chelsoni, Fraseri, regina, Mooreana, triumphans, Shepherdi, Weismanni, rex, magnifica, amabilis, and the distinct and effective species Goldieana. Smaller but equally well-conditioned plants were staged by Mr. Wills of the above-named sorts, with the addition of excelsa, Macleayi, very dark; Guilfoylei, Kaiorkiana, Youngii, and Dennisonii. Probably no finer plants than the above have ever been exhibited.

In Class 36, six new plants, Orchids excluded, Mr. Bull staged a rich group, amongst which Blandfordia princeps was conspicuously beautiful. He had also quaint Pilocerus, Lomaria Doboydeusis; Dracænas canescens, bright green and white, and Goldieana; Anthurium Scherzerianum album, and Palms in variety.

Six Lilies (open).—Nice plants were staged by Mr. Bull of Auratum, Tigrinum splendens, pyrenaicum, Szovitzianum, davauricum erectum, and bulbiferum umbellatum, and a first prize awarded. This was the only entry in this class.

Twelve hardy perennials (open).—Mr. R. Parker was first with fine specimens of Lupines, Pæonias, double Pyrethrums, &c. A smaller but a very nice group coming from Mr. Dean, Ealing. Hardy plants were not staged so well as at previous shows.

For twelve hardy Ferns (nurserymen), Messrs. J. Ivery & Son

were first with fresh good plants 3 feet in diameter, of which the different varieties of Lastrea Filix-mas and Athyrium Filix-fœmina; Polyetichums angulare, Wollastonii, and decurrens; and Osmunda regalis cristata were the most noticeable. Second place being given to Mr. R. Parker, Tooting, with small but equally attractive plants. Some of them, however, can only by a stretch of terms be pronounced hardy.

For two Dasyliriums Mr. Croucher, gardener to J. T. Peacock, Esq., exhibited two good plants and had a first prize; the first prize for six Yuccas going to the same exhibitor, who had good plants of aloifolia quadricolor, A. variegata filifera, Mooreana, conspicua, and Eylesii. Mr. Croucher was also first for two Beaucarneas.

In the Miscellaneous classes a group of Dracænas was exhibited by Mr. Wills. Mr. Laing staged Pandanuses, Ferns, Aroids, and bicolor Pelargoniums in undeniable health. Mr. Dixon, Beverley, exhibited three plants—a Dracæna, Palm, and Pteris, which did not appear to be an improvement on existing sorts. Mr. Williams exhibited a small and elegant group of ornamental decorative plants, Erica Eximia and the Flamingo Plant being particularly bright. Mr. Wills exhibited an extensive collection, consisting of a groundwork of flowering plants, relieved by Palms and Ferns, and edged with the green Moneywort—a very pleasing and attractive group, superior to that with which he won the first prize at the Palace on Saturday. Messrs. Kelway & Son set up thirty-six beautiful blooms of double Pyrethrums, and Mr. Parker twenty-four Irises and Pyrethrums.

In the class for six Cycads Mr. Bull staged a valuable group, consisting of Dioon edule, Cycas revoluta, Macrozamia spiralis, and Encephalartos majesticus, villosus, and Vroomii.

For the Davis competition prizes Mr. W. Kemp, gardener to the Duke of Northumberland, exhibited nine medium-sized plants, evidencing superior cultivation, of Gonstyllis tulipifera, Aphelexis macrantha purpurea, Acrophyllum venosum, Boronia serrulata, Dracophyllum gracile, Clerodendron Balfourii, Erica Cavendishii, and Epacris miniata splendens. For six Tree Ferns Mr. Wills was the only competitor, with specimens 10 feet in length of trunk and nice heads.

In Class 68 for prizes offered by Mr. Bull for collections of plants of his introduction, the first place was assigned to Mr. Thynne, Great Western Nurseries, Glasgow, who had a splendid Encephalartos villosus ampliatus, fine Dæmonorops palembanicus and periacanthus, Macrozamias plumosa and spiralis eburnea, Dracænas, &c.—a well arranged and excellent group. Second Mr. Wimsett, Ashburnham Park Nursery, immense Maranta, Palms, Dracænas, Crotons, &c. Mr. Cypher, Cheltenham, securing with small plants a third prize. Mr. Wright, Lee, Kent, had a first award with Dæmonorops palembanicus, Dracæoas, Marantas, &c.—a handsome collection. In Class 70 Mr. Dixon, Hull, staged a fine Macrozamia spiralis eburnea, excellent Dracænas and Crotons, Aralia Guilfoylei, Maranta Makoyana, &c., and was placed second. In Class 67 (amateurs), Mr. Croucher, gardener to J. T. Peacock, Esq., Sudbury House, Hammersmith, was first with Palms, Dieffenbachias, Dracænas, Marantas, Macrozamias, Nidulariums, &c.; Mr. Legge being second; and Mr. Pilgrim, Fairlawn, third with a nice lot of small plants. A prize was also awarded to Mr. Coomber, gardener to Lieut.-Col. Wilkinson, Fitzroy Park, Highgate, for an attractive group. In the class for exhibitors not previously winning Mr. Bull's prizes, Mr. Legge, Cleveland House Clapham Park, staged one of the best cultivated groups in the Exhibition, Dieffenbachia nobilis, truly noble; Dipladenia Brierliana, Dracænas, &c., in excellent colour.

FRUIT.

Of Grapes fifty-four bunches were exhibited. The first prize for three bunches of Muscat of Alexandria was won by Mr. Bonse, gardener to D. McIntosh, Esq., Havering Park, with nicely finished examples; second honours going to Mr. Douglas, and third to Mr. Stephenson, gardener to F. C. Barker, Esq., Leigh House, Essex. For three bunches of Buckland Sweetwater, Mr. Douglas secured the first prize with three fine bunches and a second prize for Canon Hall Muscats, immense berries, but rather poor bunches. Mr. Bones had a second prize for Dutch Sweetwater, and Mr. Bannerman second for Grizzly Frontignan. Foster's White Seedling were exhibited by Mr. Bannerman and Mr. Lane. Black Hamburghs were very fine. Mr. Douglas was first with good bunches, very black, and even in berry; Mr. Brush, gardener to Lady Hume Campbell, being second, and Mr. Bannerman, gardener to Lord Bagot, third.

Fine bunches of Black Hamburgh and Foster's White Seedling were exhibited, not for competition, by Mr. Harrison, gardener to the Earl of Derby.

Of Pines, five fruits were exhibited. For two Smooth-leaved Cayenne Mr. Miles, gardener to Lord Carrington, had first prize for good fruits. A first prize was also awarded to a fine specimen of the same variety to Mr. Harris, gardener to Mrs. Vivian, Singleton, Swansea. In Class 49 a first prize was awarded to a very fine fruit exhibited by Mr. Grant, gardener to J. B. Glegg, Esq., Withington Hall.

Handsome Tomatoes and superior Chilies were exhibited by Mr. Miles, and had a bronze medal awarded.

In Green or Pale-flesh Melons there were only two exhibitors. The first prize fell to Mr. Gilbert, gardener to the Marquis of Exeter, Stamford, with Colston Bassett Seedling. Second, Mr. W. Stevens, gardener to J. B. Elliott, Esq., Chesterfield Park, Essex. Class 66, for Scarlet-fleshed kinds, Mr. Gilbert was again first with Read's Hybrid. Second, Mr. Stevens, with Malvern Hall. Third, Mr. W. Sanders, gardener to J. East, Esq., Longstock House, Stockbridge, Hants, with Ward's Netted.

For fifty White Cherries Mr. G. T. Miles, gardener to Lord Carrington, High Wycombe, Bucks, secured the prize for a fine plate of Elton. In Black Cherries, Mr. Miles was again first with Black Circassian, also fine.

For Strawberries of the British Queen type there was a small competition. Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, came first with a dish of very fine fruit of Augusta Nicaise. Second, Mr. J. Pottle, gardener to Sir R. Wallace, Bart., Ladbourne Hall, Wickham Market, with British Queen. Third, Mr. W. S. Stevens with the same variety. For any of the Sir C. Napier or Sir Joseph Paxton type, the first prize again fell to Mr. Douglas for Dr. Nicaise. Second, Mr. Ridout, gardener to W. S. Brown, Esq., Woodhatch Lodge, Reigate, with Sir C. Napier. Third, Mr. Pottle, with Sir Joseph Paxton.

For Figs, any kind (open), Mr. J. Pottle was first with White Marseilles, and Mr. Miles second with a dish of Brown Ischia.

For a dish of Peaches, any kind, the first prize was won by Mr. Miles for a dish of well-ripened Stirling Castle, and for a dish of Nectarines the same exhibitor took a first prize.

For the prizes offered by Messrs. Sutton & Sons for six dishes of Peas there were two competitors. Mr. Pragnall, gardener to D. W. Digby, Esq., Sherborne Castle, Dorset, had fresh and full examples of William I., First Crop Blue, Emerald Gem, Ringleader, Little Gem, Bijou.

For Messrs. Carter's prize for six varieties of Peas there were also two competitors, Mr. Pragnall again winning with fine dishes of Blue Peter, First Crop, Premium Gem, White Gem, Unique, and William I..

For Messrs. Suttons' prizes for four varieties of Melons and four varieties of Cucumbers, Mr. Read, the Gardens, Arley Hall, was the only exhibitor. Of Cucumbers he had Telegraph, Tender and True, Marquis of Lorne, and Duke of Connaught. Of Melons, Golden Perfection, Horticultural Prize, Victory of Bath, and Read's Hybrid.

An erection by Messrs. Weeks & Co. representing an entrance to a conservatory was neat, strong, and ornamental, and well adapted for its purpose; it attracted the notice of visitors.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. John Gardner, gardener to Sir J. D. Astley, Bart., Elsham Hall, Brigg, sent his seedling Melon Duchess of Edinburgh, raised by crossing Bromham Hall with Bodorgan Orange, but unfortunately it was not ripe, and required ten days longer to be able to judge of its merits. Mr. John Booth, the Gardens, Osmaston Manor, Derby, sent fruit of Wright's Favourite Melon, a large, long oval fruit, with a deep orange-netted skin; but it did not possess sufficient merit to warrant the Committee to recommend it. Mr. Booth also sent another large one called Osmaston Manor, with a paler and more netted skin. This was not ripe. Mr. James Batters, the Gardens, Chilworth Manor, Romsey, sent a fruit of the true Smooth-leaved Pine weighing 5¼ lbs., which at this season was considered as an evidence of skilful cultivation, and it was awarded a cultural commendation. J. J. Watts, Esq., Whistley Farm, Devizes, sent a dish of a seedling Plum called Improved Orleans. The Committee pronounced no opinion as to its novelty, as the information they possessed on the subject was insufficient; but they awarded a cultural commendation. Mr. William Gardner, the Gardens, Eatington Park, Stratford-on-Avon, sent a dish of good early Peaches, which received a cultural commendation.

Messrs. James Carter & Co. sent specimens of their Fern-leaved Parsley, the Covent Garden Garnishing, and the Champion Moss Curled. The Fern-leaved has the leaves cut into very fine thread-like segments, and has a close knotted appearance; the others are more or less curled after the fashion of the old curled Parsleys. Henry Webb, Esq., Redstone Manor, sent specimens of young Peas very much affected with the caterpillar of a dipterous insect.

FLORAL COMMITTEE.—R. W. Postans, Esq., in the chair. First-class certificates were awarded to Mr. W. Bull, King's Road, Chelsea, for Oncidium curtum, a very ornamental species with a golden yellow lip irregularly margined with brown spots and blotches, sepals and petals brown and yellow; the growth is like O. sarcodes; to Messrs. T. Cripps & Son for Clematis Lord Nelson—it does not seem to be free-flowering, but the flowers are of great substance and of a distinct bluish purple colour; and to Mr. B. S. Williams, of Upper Holloway, for Polystichum lepidocaulon. Second-class certificates were voted to G. F. Wilson, Esq., of Weybridge, for Lilium Hansoni, a very fine species of the Martagon group. It was figured in the "Botanical Magazine" as L. avenaceum. The leaves are

arranged in whorls as in L. Humboldtii, and the colour and spotting are also similar to Humboldtii. To Messrs. Crippe for a very free-flowering sweet-scented Clematis named Lady Alice Nevill; and to Mr. W. Bull for Pelargonium Prince of Wales, a bright red variety of the Queen Victoria type.

Mr. Wilson had Lilium Thunbergianum splendens, certainly the finest of the species that has yet been shown.

Messrs. Cripps sent seedling Clematis Blue Perfection, Maid of Kent, and Duke of Edinburgh, Quercus striata, and Crataegus filicifolia. Cut Aquilegias camo from Mr. Webster of Gordon Castle; and Æchmea Maria Regina from Messrs. Dixon of Beverley.

A vote of thanks was given to Messrs. Veitch of Chelsea for a collection of cut flowers of Ixias, Iris, &c.

Messrs. W. Barron & Son, Elvaston Nurseries, Borrowash, Derby, sent a collection of new Coniferous plants—Retinospora tetragona aurea, a very pretty species from Japan; Cupressus Lawsoniana elegantissima, which has more white in its composition than any other variety, and if true to its character will be very useful; Taxus elvastonensis aurea, very distinct; Retinospora pisifera aurea, very fine. Many other distinct species were in the collection.

Mr. E. Holmes, Whittington Nurseries, Lichfield, sent a species of Juniper from Virginia, an erect-growing species of graceful character. Seedling Pyrethrums from Messrs. Kelway of Langport, Galopin red and Eugénie white, were of very fine character. Mr. W. Thomson of Clovenfords Vineyard received a vote of thanks for a very spike of Vanda suavis with nineteen flowers.

BATH AND WEST OF ENGLAND SOCIETY'S SHOW.

CROYDON, JUNE 1st.

THE horticultural tent at the Bath and West of England and Southern Counties Association is always a prominent feature of attraction to visitors. This year it is no exception, for the Hon. and Rev. J. T. Boscawen has spread a floral feast of no mean order. He has disposed of his material to the best advantage, and produced an example of plant-grouping which is—as it was meant to be—instructive. As a rule the arrangement of plants is too close and formal, notably was this the case at the Palace on Saturday last. But Mr. Boscawen will tolerate no crowding, or permit no flatness, whereby one plant only hides the deformity of another. Neither will he follow the stereotyped plan of arranging the "highest at the back;" but he boldly brings to the front towering Tree Ferns, and around their stems is grouped in the most agreeable manner Orchids, Mosses, and stove plants.

This, it must be remembered, is not an ordinary exhibition, where the plants are grouped in classes, but the whole are arranged with a view to the best aggregate effect. Thus we find a charming combination of Adiantum farleyense and brilliant Cattleyas. We find splendid examples of Utricularia montana from Sir W. Marriott associated with noble Stag's-horn Ferns from Messrs. Rollisson & Sons, and elegant Palms from the Rev. A. H. Bridges. We notice handsome stove plants from Mr. Stephenson Clarke intermingled with equally good specimens from Mr. Crowley, and Orchids from Mr. Brymer. We find gorgeous Rhododendrons from Mr. Noble surmounted with handsome Dracænas from Mr. Bridges, and flanked by Palms from Messrs. Rollisson. Thus does Mr. Boscawen exercise his taste, and labours with an energy which commands success to spread a feast not only for gratification but also for instruction.

To enable him to carry out his designs he solicits plants from all who are able and willing to contribute, and sends the best acknowledgment in his power to gardeners who respond to the invitation. Thus voluntaryism and good feeling are the main springs of the Exhibition, and whoever knew these agencies to fail? True some large exhibitors failed to fulfil engagements, but even that was a favour rather than otherwise, for the tent was filled, and any further addition would have been an incubus rather than an attraction.

Amongst those who contributed to the Exhibition was Mr. King, gardener to Stephenson Clark, Esq., Croydon Lodge, who sent an extensive collection, comprising Palms, Ferns, Pandanuses, Selaginellas, a good Clerodendron, and the bright yellow Verbascum chrysophyllum. The plants were healthy and well grown. Equally good were those from Mr. Strachan, gardener to Philip Crowley, Esq., Waddon, consisting of good Crotons, a fine Rhyncospermum, an excellent Blandfordia nobilis, Ericas, Dieffenbachias, Gloxinias, and the attractive Saxifraga nepalensis. Mr. Penfold, gardener to Rev. A. H. Bridges, Beddington House, sent excellent Palms, Tree Ferns, capital Dracænas, Nepenthes, a very good Maranta fascida, &c. Mr. Hill, gardener to Sir W. Marriott, Down House, Blandford, sent remarkably well-grown Orchids and other good plants. Orchids also came, both in plants and cut blooms, from W. E. Brymer, Esq., M.P., which were well grown and interesting. Messrs. W. Rollisson & Sons, Mr. B. S. Williams, and Mr. Noble also contributed well; and Messrs. Paul & Son, Cheshunt, sent their specimen Roses. The plants are being admired by thousands of visitors, and Mr. Boscawen has the satisfaction to feel that his labours are appreciated.

In the show grounds we noticed as prominent objects the seed and root museums of Messrs. James Carter & Co. and Sutton & Sons, which are enjoying a good share of patronage. Horticultural erections are exhibited by Messrs. Dennis & Co., Boulton & Paul, Parham, Cranston, &c. The weather is bright, and visitors numerous.

CRYSTAL PALACE FLOWER SHOW.

MAY 29TH.

A FALLING barometer on Friday, and a drizzling morning succeeding, portended an unfavourable day for the first great summer Exhibition, which was held in the Central Transept on Saturday last. The day, however, although dull was dry, and enabled a large number of spectators to visit the Palace and Show. It was worthy of their patronage, for the display was an excellent one, equal, perhaps, to the best of past years, and superior to most of them. But the most gigantic plants appeared dwarfed in this lofty transept in comparison with the effect the same plants would produce in a large marquee. Still, even in the Palace the noble Roses, gorgeous Azaleas, massive Heaths, and fine stove and greenhouse plants asserted their power of attraction, and compelled a recognition of their intrinsic excellence. Not quite all the classes were filled, but in most of them was good competition, and an idea of their numbers is conveyed when we note the plants extended down each side of the transept to a length of 150 yards.

In the nurserymen's class for twelve stove and greenhouse plants Messrs. Jackson & Son, Kingston, occupied the premier position with remarkably good specimens, of which the most striking were Azalea Petuniæflora, a huge pyramid of rich pink; Anthurium Scherzerianum, good; Dracophyllum gracile, a remarkable close and fine specimen; Boronia pinnata, an excellent plant; Hedaroma tulipifera, very fine; with Clerodendron Balfourii, Aphelexis macrantha purpurea, Pimelea Hendersoni, very dense; and Erica depressa multiflora. Mr. B. S. Williams had second honours with a valuable group, comprising Azaleas, Aphelexes, Ericas Tricolor Wilsoni, and Cavendishii, Hedaroma tulipifera, Allamanda grandiflora, very bright; Bougainvillea spectabilis, Medinilla magnifica, &c. Mr. Morse, Epsom, was third with smaller but good plants, of which Hedaromas, Aphelexes, Ericas, and an Ixora were the most effective.

In the amateurs' class Mr. Ward, gardener to F. G. Wilkins, Esq., secured first honours with nine splendid examples, consisting of Anthurium Scherzerianum with about fifty spathes, an immense Genetyllis tulipifera, a handsome Statice, a good Erica and Aphelexis, a capital Azalea, &c. These were perfect globes of bloom of 5 to 6 feet in diameter, and in excellent condition. Mr. Chapman, gardener to J. Spode, Esq., Hawkyard Park, and Mr. Peed, gardener to Mrs. Treadwell, St. John's Lodge, Lower Norwood, were placed equal second. Mr. Chapman's best plants being a grand specimen of Ixora Prince of Orange, Heaths, Eriostemons, and Azaleas. Mr. Peed's, which were larger but not better, consisting of Clerodendron Balfourii, Francisceas confertifolia and calycina, Azaleas, &c.

In the nurserymen's class for fine-foliage plants Mr. Williams staged a group of large plants, but deficient in light and bright colours, which did not show to advantage with the fine lively groups of the amateurs. In these Mr. Legge, gardener to S. Ralli, Esq., Cleveland House, Clapham Park, was worthily placed first with a well-grown collection, bright, fresh, and beautiful. Crotons Weismanni and Younghii were admirably finished, while Dracæna Baptistii, Alocasia Lowii, a Dieffenbachia, and Palms were in excellent order. Mr. Chapman, gardener to J. Spode, Esq., was placed second with larger plants but less bright, consisting principally of Palms. Mr. Child, gardener to Mr. Torr, Garbrand Hall, being third, his best plants being Gleichenia speluncæ, a Dicksonia, and a highly coloured Croton Weismannii.

In the nurserymen's class for nine Cape Heaths Messrs. Jackson & Son secured first honours with plants combining good size with fine quality. The best were Ericas ventricosa coccinea minor, mutabilis, Shannoni, ventricosa grandiflora, and tricolor speciosa; Mr. Morse being second with medium-sized well-bloomed plants, of which E. Devoniana, E. Perspicua nana, and E. Westphalengæ were noticeable. Amongst amateurs Mr. Ward was first with six plants of undeniable excellence, embracing a gigantic example of Cavendishii, a fine Tricolor impressa, Eximia superba, a model, and a densely-bloomed Elegans. Mr. Peed was placed second with good Ventricosas, a superior Eximia, &c.; and Mr. Wheeler, gardener to Sir F. H. Goldsmid, third.

Azaleas were excellently shown; in the nurserymen's class Mr. Williams was the only prizetaker; the collections were extremely effective. In the amateurs' class of six plants Mr. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham Hill, was a good first, with enormous pyramids fully 6 feet across the base and 7 feet high, each well finished. His most noticeable

plants were Holfordiana, Miltoni, Criterion, Stella, Gladstaneaii formosa, and Extranei. Mr. Child was second with obtuse pyramids 6 feet high, and Mr. Roach, gardener to C. Dorman, Esq., The Firs, Sydenham, third; the most attractive plant of his group was Model. Mr. Peed also exhibited well. In the open class for twenty plants Mr. Ratty was first with immense globular and pyramidal specimens in 15 and 18-inch pots; Mr. Turner, Slough, being second with medium-sized plants in 8 and 9-inch pots, the best sorts of which were noticed last week. In this class was a disparity between the schedule and exhibition card, the latter stating the pots should not exceed 12 inches in diameter, but as the schedule did not determine the limit Mr. Ratty was entitled to the prize for his fine collection, anomalous as appeared the award and condition card.

Orchids were a rich display. In the nurserymen's class for twelve Mr. Williams was first with the finest group this year exhibited. His Cattleyas were grand, Cypripedium barbatum very fine, Dendrobium densiflorum an excellent example, and the rest good. Messrs. Jackson & Son had second honours with a fine Cattleya Mossiæ, a beautiful C. Mendeli, excellent Vandas, &c. In the corresponding class for amateurs Mr. Ward won the premier place with a fine collection, the best being Dendrobium thrysiflorum with four fine racemes, Lycaste Skinneri, Odontoglossum Bluntii, Pescatorei, and phalænopsis, Cattleya Mossiæ superba, Oncidium sarcodes, &c., all the plants being in rare health and finely bloomed. Mr. Gray, gardener to H. Smithies, Esq., had second place with good plants, and Mr. Wheeler being placed third. In the class for six Mr. Ward was again to the fore; in this group he staged Odontoglossum vexillarium in fine form and colour, Phalænopsis grandiflora, Odontoglossum phalænopsis, Oncidium ampliatum, &c. Mr. Child was second with, amongst others, good plants of Aërides Fieldingi, Dendrobium Farmeri, Oncidium ampliatum major, and Cypripedium Stonei. Mr. Budd, gardener, Heathfield, had the third place. Mr. Peed also exhibited.

Mr. Lambert, gardener to H. W. Segelcke, Esq., Herne Hill, was placed first for six table plants with Cocos Weddelliana and other Palms, Adiantum gracillimum, Dracæna gracilis, &c. These plants were fresh and bright in small 32 sized pots. Mr. Hudson, gardener, Champion Hill, and Mr. Wills, Exotic Nursery, Onslow Crescent, were equal second. Mr. Hudson's best plants were Pandanus Veitchii and Croton Johannis, both in fine order; Mr. Wills having Aralia Veitchii, Pandanus Veitchii, Terminalia elegans very fine, Croton Weismannii, &c., Mr. Wheeler having the third place. Six excellently-grown Selaginellas were staged by Mr. Collins, gardener to R. H. Bristowe, Esq., Sydenham Hill, which were worthy of recognition.

In the class for nine Dracænas Mr. Wills was the only exhibitor. He staged plants of rare excellence.

Pelargoniums were well represented. For nine plants in 8-inch pots Mr. Turner had the premier award with symmetrical plants 3 feet through, good in bloom and colour. The best were Example, Mary Doyle, Blue Bell, Prince Leopold, Pompey, and the delicate white and pink Claribell; second honours going to Messrs. Dobson & Sons with Conqueror (lilac), Beacon, Thetis, Atalanta, Eclipse, &c. The above were not flat, but naturally-grown plants. In the corresponding amateurs' class Mr. Ward was first with the largest flat-trained plants in the Show, the most noticeable being Warrior, Prince Leopold, Maid of Honour, Royal Albert, and Mary Hoyle. Mr. James, gardener to W. F. Watson, Esq., having the second award with a level excellent group, the best being Prince Leopold, Snowflake, and Mary Hoyle. In the Fancy class Mr. Turner was first with well-bloomed medium-sized plants of Mrs. A. Wigan, Brightness, Neatness, Madame Sainton-Dolby, Ellen Beck (good), Acme, &c.; Messrs. Dobson & Sons being second with nearly the same varieties; a third award being given to Mr. Foreman. Mr. James, however, exhibited in the miscellaneous class the six best Fancies in the Exhibition.

Roses were numerous and fine. For nine plants Messrs. Paul and Son, Cheshunt, and Mr. Turner, Slough, the redoubtable champions, being placed first and second respectively. Messrs. Paul's plants were uniformly large; Mr. Turner's containing specimens unequal as to size. The blooms in both groups were grand, of the same sterling old varieties which have been previously enumerated. Who after witnessing these noble bushes would spend their strength on perfecting standards? In the class for twenty plants Mr. Turner walked over with fresh and beautiful specimens of popular varieties. For six plants (amateurs) Mr. E. Ellis, gardener to J. Galworthy, Esq., Coombe Warren, Kingston Hill, was first, and Mr. J. Mooreman, gardener to the Misses Christy, Kingston, second, with highly creditable collections.

In the Clematis class Messrs. G. Jackman & Son had no competitors. They staged Alba magna, the best of all; Mrs. Hope, lavender blue; Mrs. Gassiot, silvery lavender; The Queen, Vesta, &c.

In the groups arranged for effect Mr. Wills and Mr. Waters, gardener to A. Mongredien, Esq., were equal firsts. Mr. Wills' were good rich-foliaged plants, brightened by Azaleas, Spiræas, and Pelargoniums; Mr. Waters' group was composed almost wholly of flowering plants, which were good, but were too close and formal in the arrangement. Mr. Foreman, gardener to E. E. Nicholson, Esq., was second with a good and well-arranged collection; Mr. Peed being placed third for good plants, but deficient in foliage. Very effective groups were also staged by Mr. Thompson of the Crystal Palace.

For new and rare plants Mr. B. S. Williams was placed first with an interesting collection. Towering above the group was a grand weeping Tree Fern, Alsophila Williamsii, a plant of undoubted value and intrinsic beauty. He had also Dracæna Fraserii, Dipladenia Brierliana (a richly-coloured variety), Croton majesticum, Metroxylum filiare, &c. Mr. Ley, Croydon, was second with ornamental and healthy plants of Zamia Lindeni, Calamus pnyamo very good, Palms, Dracænas, &c.

Seedling Pelargoniums were exhibited by Mr. Foster and Mr. Turner. Of the show varieties Mr. Foster had certificates for Grace, Prince Rupert, and Malcolm; and Mr. Turner for Fancies Countess of Dudley, Duchess of Edinburgh, and Mrs. R. Baker; also to Forcing Pink Derby Day, a great improvement on Anne Boleyn.

Miscellaneous groups of plants were exhibited by Mr. Williams and Mr. Wills; fine tree Mignonette by Mr. Coulter and Messrs. James Carter & Co., who also had their striking Coleus Duchess of Edinburgh. Messrs. Dobson & Sons exhibited superior Calceolarias; and Mr. Satchell, gardener to J. W. Anderson, Esq., and Mr. Waters also had good collections. Mr. Parker, Tooting, staged a beautiful collection of hardy plants; Mr. Hooper, Bath, handsome cut blooms of double Pyrethrums and Pansies; Mr. Taylor, Headington, Oxford, charming boxes of Rose Devoniensis; and Mr. Chapman, Oxford, highly coloured Maréchal Niels. Mr. Smith, Isleworth, had variegated Pelargonium Alice. Mr. Laing exhibited an attractive group of plants, including finely coloured bicolor Pelargoniums; Mr. John Spittle, Birmingham, a collection of Tulips; and last, but not least, Messrs. Jackson & Sons staged charming plants of a hardy Saxifrage, S. nepalensis. These plants were perfect pyramids of bloom 2 feet high, literally covered with thousands of white star-like flowers.

First-class certificates were awarded to Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, for a number of new plants.

VINES UNDER GLASS.

A Practical Treatise on the Cultivation of the Grape Vine. By W. Thomson, *Tweed Vineyard.* Eighth Edition, enlarged. W. Blackwood & Sons, Edinburgh and London.

The fact that seven editions, amounting to ten thousand copies, have been sold in twelve years, and that the eighth edition is then required, is a testimony far surpassing any favourable criticism we can offer on the volume before us. It is the testimony of the gardening community. A thoroughly reliable guide for growing Grapes under glass was expected from Mr. Thomson, his practical knowledge and ability justified the expectation, and it has not been disappointed. In thirty-eight sections everything needed for instruction how to cultivate the Vine under glass, to avoid or overcome its diseases and insect enemies are detailed. On open-air culture Mr. Thomson scarcely gives any information, and he should have qualified his sentence that in Britain "the Grape Vine can only be grown in the open air with very partial success," by prefixing the word "North" to "Britain," for in the southern districts of our island it is so grown largely, and the outdoor cultivation is annually increasing.

ROYAL HORTICULTURAL SOCIETY.

My attention has been drawn to your number published May 20th, which evidently refers to me in a manner more pointedly than complimentary. I therefore request you in your next issue to state that your informant, whoever he may be, has no authority for the statement supplied you, that "in my capacity of auditor of the Society's accounts I have so egregiously failed as to pass accounts as paid which never have been paid, and for which I never could have seen the vouchers."

I beg to assure your readers that the accounts of the Society are well kept, that accounts are no novelty to me, and that I saw vouchers for every item; that I ventured to examine somewhat into the accounts prior to the year for which I was the auditor, and found ample evidence of the recklessness with which the displaced Council has brought this honourable Society to the verge of ruin.

If ruin is the unfortunate fate awaiting us the entire fault lies with the gentlemen who have left the present Council a legacy of debt beyond the power of any body of men to cope

with, against the antagonistic and open hostility of Her Majesty's Commissioners of 1851, who clearly care less for horticulture than I did when I first became a Fellow for the pure love of flowers upwards of thirty years ago. I may further add that the accounts have also the advantage of being vouched for by one of the most eminent firms of public accountants in England, so that the Fellows of the Society may feel certain of their accuracy.—HENRY LIGGINS, 3, *Ladbroke Square, W.*

[In the statement of revenue and expenditure for the year 1874 issued by the Council along with the report at the last annual meeting, there is credit taken by the Society for having paid the Pomological Director the sum of £95 16*s.* 6*d.* This statement is signed HENRY LIGGINS, *Auditor*. We are informed that not only has the Pomological Director never received a farthing of that amount, but that no such amount is due to him for the year 1874. Does Mr. Liggins assert that he saw the receipt of the Pomological Director for that payment?]

EARLY POTATOES.

THE Ashleaved Kidney Potatoes in Cork Market look riper than any I saw last week in Covent Garden Market. I am told the market here has been supplied during the last three weeks. You would be benefiting the farmers here if you could persuade them to devote fields to the cultivation of early Potatoes, Peas, &c., as their communications with Liverpool are so cheap and quick by water that with three-weeks advantage of climate, ventures in this way would certainly turn out remunerative.—P. N. W.

[Repeatedly we have advised the growers of Potatoes to cultivate none but early-ripening varieties. When we grew Potatoes we planted none but the true Ashleaved, took up the crop in July, stored them in layers alternating with sand in a dry cool cellar, and they were undiseased and supplied the table until new Potatoes were ready the next year.—EDS.]

THE ROYAL HORTICULTURAL SOCIETY—MASTER AND GARDENER.

LIKE other exhibitors I was much interested in the result of the Special General Meeting of the Royal Horticultural Society, and hoped against hope that something would arise out of the Meeting that would place the old Society once more upon a firm foundation, whereon we could all work together for the furtherance of the art for which the Society was instituted. Our expectations have once more been doomed to disappointment. Probably this will always be so until the Council are advised to consult the leading horticulturists as well as the general body of Fellows when they are in any difficulty.

About five or six years ago, when it was thought desirable to amend the schedule, all the exhibitors were summoned to a meeting convened by the Council by circular, and his Grace the Duke of Buccleuch did not think it derogatory to preside over that meeting, supported by the late lamented Bishop of Winchester. I was present as an exhibitor, and had the opportunity of stating my views on the matter with other gardeners. Major-General Scott, the Society's late Honorary Secretary, was also present, and everything was arranged to our entire satisfaction. Now, if a meeting of this sort had been convened at the time the Council determined to make the 50 per cent. deduction from the prizes, the exhibitors to a man would have supported the Council in whatever arrangement it was thought desirable to adopt: but unfortunately the present men who are in power prefer sledge-hammer argument to any system of conciliation. This was fully proved in the unwarrantable attack made by Lord Bury and the Treasurer of the Society on gardeners and their employers.

It is entirely the fault of the Council that the Fellows have to bear the humiliation of being dragged into the County Court, and I wish to state fully at the same time that I do not approve of the action taken by the exhibitors. Although one of the largest creditors amongst them, and however much I disapprove of the way the Council have managed the Society this year, I have too much respect for the honour of the Society ever to be prevailed upon to take action against them.

Another reason—fortunately I am not one of "those men" who are paid out of the prize funds. My kind employer pays large sums of money annually to support the exhibitions, and never has inquired how or when I receive the prize money. He was kind enough to say, when I thought it my duty to ask who was to receive the prizes, "You, of course;" and that is all that has ever passed between us about them.

Then as to wages. An employer might say, "Well, my gardener is making a good thing out of his prizes, it will not be necessary for me to raise his wages as I would have done if he had not been competing." This could hardly be said to be paying the gardener out of the prize money, but it would amount to the same thing. It has not been so with me; my employer naturally supposed that as his gardener was able to carry off a very large proportion of first prizes he must be a good gardener and worthy of encouragement, and my wages have been much increased in consequence.

I would rather—much rather—have refrained from entering into any personal relations between master and gardener; but if there is any impropriety in doing it the blame rests with Lord Bury, and his lordship either ought to say who are the employers who pay their gardeners partly out of the prize money, or if he cannot do this make ample apology for the expressions he has used. I am personally acquainted with nearly all the exhibitors, have known and had intimate relations with the most prominent of them for many years, and never yet have I heard any gardener say that part of his wages was paid out of his prize money. If reckless unproved statements continue to be made at meetings by members of the Council, and bitter feelings thereby engendered, the reconstruction of the Society on a satisfactory basis will be impossible.—J. DOUGLAS, *Gardener to Francis Whitbourn, Esq., Loxford Hall.*

NOTES AND GLEANINGS.

WE are informed that Professor W. T. THISLETON DYER is appointed to the office of Assistant Director of the Kew Royal Gardens.

—— PARSLEY.—In the neighbourhood of Chobham, Surrey, they have a lore that if Parsley seed be sown on any other day than Good Friday it will not come double.—(*Notes and Queries.*)

—— WE have before us two PORTRAITS OF ROSES raised by Mr. W. Paul. We usually mistrust coloured portraits of flowers, but as we have seen one of these Roses, Star of Waltham, and the picture is no exaggeration of that very fine and sweet-scented flower, we are willing to believe that the other portrait of Queen of Waltham is truthful, and if so, it is a still finer Rose than Star of Waltham.

—— THE PRIZE LIST of the Stamford Horticultural Show to be held on September 15th and 16th is most liberal. The premiums amount to £300. There are thirteen silver cups and no entry fees. Nottingham also offers in prizes for the Show on July 8th, 9th, and 10th the sum of £750, the Rose prizes alone being £240, which should ensure a free response. Liberal prizes are also offered at Burton-on-Trent on the 16th inst., and at Wakefield on August 28th.

—— "JACK-BOLLS."—This is a pet name for Potatoes in this part of Dorset. It has occurred to me that possibly this name may be a perversion of "jack-bowls," the smallest ball in the game of bowls, once most popular in this county, as elsewhere, being denominated the "jack," and fairly representing in size an average, or somewhat large, Potato.—C. W. BINGHAM, *Bingham's Melcomb.*—(*Notes and Queries.*)

SWEET-SCENTED ROSES.

I QUITE agree with my good friend Mr. Camm that the absence of scent is very much to be deplored in any variety of the queen of flowers; but while I delight very much in the perfume of the Tea Roses, I do not think it is to be compared with that of many of the Hybrid Perpetuals. To the list of those already given would you allow me to add that of a Rose which for this and its other good qualities deserves to be better known than it is, especially as it is an English-raised flower—I mean Van Moltke, raised and sent out by Messrs. Bell of Norwich? I gathered a bloom of it to-day from one of the few pot Roses I have, and anything more fragrant it is impossible to conceive—I mean in that peculiar attar of Rose perfume which is so grateful; while in build it is not unlike a really fine Alfred Colomb grown out of doors. I have not often seen this Rose recommended, but I believe it to be a really desirable variety.—D., *Deal.*

MANY thanks to Mr. Camm for broaching this odoriferous subject. I had determined—seeing that there will not be a general election of Roses this year, the Rose parliament being

biennial—to take up the matter of fragrance this year, with the consent, of course, of the powers that be. It will be well, then, for noses to be on the alert. In one of the replies received last year the subject was suggested, and I think it may be taken up this year, coupled with an election of the newer Roses. At least this is the idea that has occurred to me in connection with Rose elections for the present year.—JOSEPH HINTON, *Warminster*.

("The powers that be" cordially assent.)

NOVELTIES IN THE ROYAL GARDENS, KEW.

CHRYSANTHEMUM CATANANCHE, one of the choicest introductions resulting from the expedition to Morocco of Dr. Hooker, Messrs. Maw and Bull, is flowering on the rockwork. Besides being new to the science of botany, it is the *beau ideal* of a rockwork plant, being a dwarf perennial, brilliant in flower, and quite hardy. The rootstock branches freely, forming a dense tuft of many heads, with silvery leaves cut into linear segments. The flower stems are erect, 3 to 6 inches high, bearing one capitule nearly 2 inches in diameter, with the rays of a creamy yellow colour, and a band of rich maroon round the centre. The involucral bracts are broad, silvery white, and of hyaline texture, thus resembling Catananche, whence the specific name. On the Greater Atlas, at elevations of from 7000 to 9000 feet, it forms large patches on the slopes exposed to the sun, and in the rocky valleys. It is increased by division without loss, every piece being willing to grow. This is a good alpine for pot cultivation, succeeding well in such confinement.

Æthionema coridifolium of the "Botanical Magazine," a plant of true beauty, is here in flower. We do not mean that with the same name well known long ago, and sometimes as a beautiful weed; but quite a different plant from a cultivator's point of view—the Iberis jucunda of Scholt and Kotschy, introduced some time ago by Messrs. Backhouse. It is no less charming, and having a delicate less rambling habit is more suitable for select rockwork of limited extent. The height in this case is about 3 inches, and every branch bears a dense raceme of pink flowers. Truly they are more like Æthionema than Iberis, therefore a good name to distinguish it from the original would be Æ. jucunda. It certainly belongs to the former genus, and not the latter. Native of Asia Minor and Lebanon.

Philydrum glaberrimum is flowering in the Temperate house, and, like the above Chrysanthemum, is new to science as well as to cultivation. It was introduced by Mr. William Bull. Though not possessing the showiness necessary for popular decoration, it is ornamental, and also of botanical interest. It forms a tuft 3 feet high, of dark green ensiform leaves an inch in breadth. The flowers are ivory white, thickly disposed in handsome panicles, which rather exceed the leaves. This makes a third species for the curious order Philydraceæ, there having been only two known hitherto, each forming a genus. It is supposed to be a native of the Pacific Islands. Philydrum is remarkable and interesting from the flowers having a dimerous perianth and only one stamen.

Azalea linearifolia flowering in the same house may be defined as a floral *curio*. The leaves are graceful, about 3 inches long, and very narrow. The corolla lobes are also long and narrow, and being divided to the base, or nearly so, render the plant quite distinct and unique in appearance. It is a native of Japan, and cuttings strike freely.

MARKET GARDENING AT MANCHESTER.

THE township of Sale was once called Sale-moor, and properly so, for the greater part of it was covered with heather, growing in thin black light soil resting on a bed of gravel and white sand 12 feet deep. It is fast being covered with good property, and becoming a healthy suburb of Manchester. It is five miles from Manchester, and is on the Cheshire side of the river Mersey. The trade of the place may be said to be market gardening; indeed it seems to form the central township of an extensive camp of market gardeners. The Smithfield Market of Manchester, like Covent Garden of London, is the central vegetable mart for an immense population. Many of the large and populous towns of Yorkshire, and almost all in Lancashire save Liverpool perhaps, are chiefly supplied with vegetables from the Manchester mart. And the greater part of them are grown in this neighbourhood.

The soil here is exceeding light and hungry, but healthful and easily worked. It is rented at about £5 and £6 per statute acre, and stable manure costs 10*s*. per ton. Notwithstanding the high rent and dearness of manure the market gardeners seem to do well, being industrious and clever in working and cropping their land. The London market gardens, and the rotation of crops taken from them, interested me much some twenty or thirty years ago. First came Radishes and Lettuces, which realised from £40 to £50 per acre; next a crop of French Beans, and this was followed by Colesworts, all well done in one year, and profitable. The farmers in this locality catch the spirit of the market men in endeavouring to obtain all they can out of their land.

Strawberry-growing forms a large element of market gardening here. Many farmers make large plantations of Strawberries, and realise, I am told, about £100 per acre in good seasons from the fruit. The soil here evidently suits Strawberries, for it yields heavy crops of them for many years in succession. As soon as possible after the fruit is picked the leaves of the plants are mowed off with a scythe and the beds dressed a little. This is all that is done. Someone may say the cutting the leaves off is a mistake, or as the late Dr. Lindley put it some thirty years ago, it is like cutting the lungs out of a man. The leaves were cut off the plants thus in the garden where I served my apprenticeship, and the plants bore immense crops. In this locality the practice answers well. I am of opinion that the young leaves do more real work for the plants than the old foliage would if left on. The price paid for gathering Strawberries is 6*d*. per dozen quarts, and we have heard of able hands earning very great wages at the commencement of some seasons.

Manchester is celebrated for its Celery, and nowhere else can we find better Celery, seldom any so good. The men here make no fuss about growing fine Celery. The drills are made and manured in the ordinary way, but the plants are planted early and small from the seed bed, instead of being pricked out and coddled in a frame. I never saw Celery from a gentleman's garden equal to some produced for the Manchester market. The plants when dibbled in the trenches are so small that they can scarcely be seen for a time. Celery makes a profitable crop, and is quite equal to fallowing for cleansing foul land. As Celery is much hardier than most gentlemen's gardeners fancy, some of them would do well to try early plants from the seed bed.

Horseradish of all vegetables has the least attention given to it in a gentleman's garden, and is generally grown in some out-of-the-way corner, owing, in some measure, to the fact that when once in the ground it is difficult to eradicate. At Stretford and adjoining township, on the Lancashire side of the river, Horseradish is grown and produced in beautiful condition, every stick of it thick, straight, and clean, very unlike the short knobby, knotty, ugly stuff so often produced from the odd corners already alluded to. Horseradish here is grown somewhat after the fashion that Seakale roots are prepared elsewhere. Long roots of it (Horseradish) are taken up, and the side roots on these are cleaned off, so there will be at least 12 inches of clean stems from the crowns or leaves to the feeding roots. These long roots are planted in a slanting direction underneath the ground, and when fully grown they may be taken up as large and straight as an Altrincham Carrot. They fetch a good price at the proper season.—A. PETTIGREW.

THE EVERGREEN OAK.

OF this, *Quercus ilex*, there are seven varieties:—1, *Integrifolia*, plain-leaved; 2, *Serratifolia*, saw-toothed-leaved; 3, *Fagifolia*, Beech-leaved; 4, *Crispa*, leaves wrinkle-edged; 5, *Latifolia*, broad-leaved; 6, *Longifolia* or *Salicifolia*, long or Willow-leaved; 7, *Variegata*, white-edge-leaved.

Which of the varieties a correspondent, "M. F.," intends to plant we do not know, but we can say that the foliage of all is very dark green, and that it is a tree which rarely is effective unless planted far in the rear of others with paler foliage; it then gives an appearance of depth to any recess.

It is one of the best of trees for affording shade to a seat placed beside its stem. An example may be seen near the Round Pond in front of Kensington Palace. A tree similar to our engraving is now in flower at Loxford, the delicate green of its catkin-like inflorescence contrasting finely with its foliage, and is very ornamental.

Near London and in the more southern counties it grows rapidly from the planted acorn, attaining to about 20 feet in height in ten years. It then grows slower in tallness, but

spreads rapidly, and becomes the good shader we commend it for.

The Evergreen Oak does not well bear transplanting, and Mr. Robson some years since published in our pages—"I believe the most successful results have been accomplished by planting in May, and even at the end of that month; but I only give this advice on the authority of a friend, as I have not personally transplanted at that time. Young trees are also recommended. If the weather is dry and bright some shading is desirable for a few days, and a shower of rain will work wonders; by the end of summer the tree will have assumed its proper costume, and all will go on well. If I had a plantation of this tree to make in the autumn I would be disposed to adopt the most primitive mode of all, and that would be to

Fig. 101.—Evergreen oak (Quercus Ilex).

put in the acorn where the tree was to grow, and if the soil and subsoil were all right I would leave the rest in a great measure to Nature."

In the excellent and accurate little volume published by The Christian Knowledge Society on "The Forest Trees of Britain," by the Rev. C. A. Johns, it is noted that the Evergreen Oak is a fellow-countryman of the Latin classic poets, from whom it has received frequent and honourable mention. Even with us it attains a considerable size; but in the milder climates of Italy, Spain, &c., it becomes a large tree, and reaches an age equal to that of some of our most venerable Oaks. Hence it not unfrequently acquired an historical interest, and for this reason perhaps, more than for its picturesque beauty, it was made the theme of poetic song. The Roman naturalist Pliny, who flourished in the first century of the Christian era, mentions a tree growing in the Vatican which claimed a higher antiquity than Rome itself. It had brazen letters in the ancient Etruscan characters affixed to its trunk, from which it would appear that, before the Roman name was known, it was a sacred tree. Its age must therefore have been eight hundred years at least. The shape of the leaf varies greatly in different individuals, and even not unfrequently on the same tree, being sometimes scarcely notched at all, at other times deeply serrated, and at others quite quickly. It is this last

variety which has procured for it the name of "Holm-Oak." It also resembles the Holm or Holly tree, in having its most prickly leaves on the lowest branches. The acorn, which does not arrive at perfection until the second year, resembles that of the Oak, but is somewhat more slender, and the cup is scaly. Some trees bear sweet and edible acorns; those produced by others are bitter, and both kinds are sometimes to be found on the same tree.

THE VERATRUMS.

The Veratrums or Hellebores are a genus of plants possessing powerful medicinal properties; indeed they are highly poisonous, owing to the peculiar alkaline principle found in the root, and known as veratrin. A small dose of this administered to the lower animals is sufficient to cause instant death. It also acts with singular energy on the mucous membrane of the nose, exciting violent sneezing if only the most minute particle is taken. The leaves of V. album when reduced to powder form the well-known white hellebore which has been used so effectively in destroying the Gooseberry caterpillar. But as being ornamental rather than medicinal we would notice this family of plants.

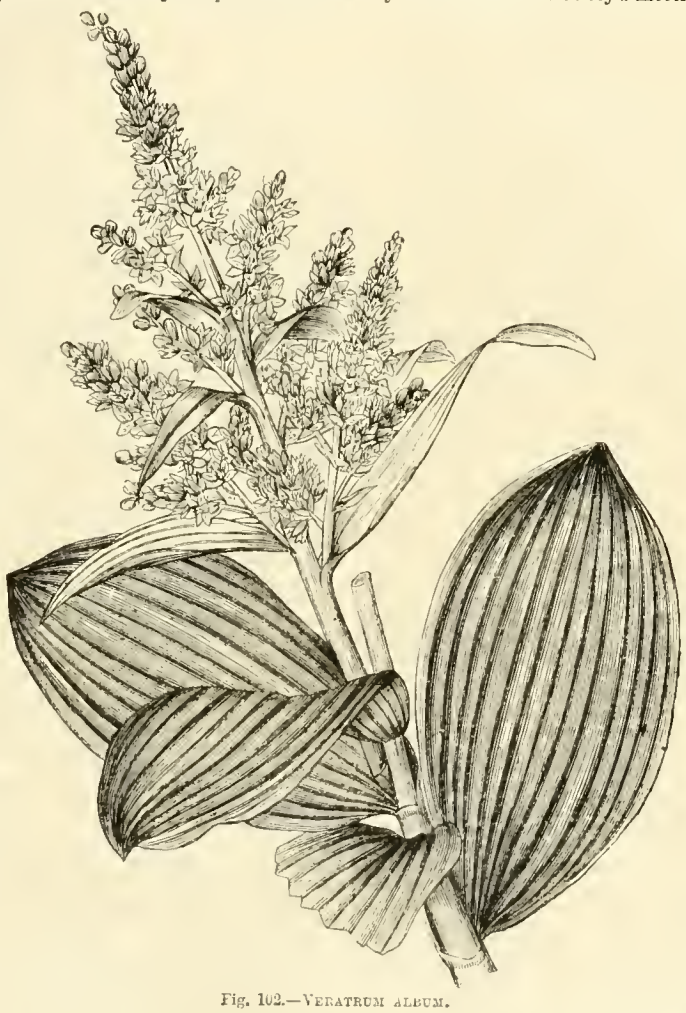

Fig. 102.—Veratrum album.

The name of Veratrum is taken from *vere*, truly, and *ater*, black, in allusion to the colour of the roots. They belong to the natural order of Melanthaceæ, and are hardy herbaceous perennials. Some of the species are handsome border plants of distinct and stately appearance. They add to a noble spike of flowers foliage which is distinctly ornamental by its stout texture, expansive form, and the bright green and regularly corrugated appearance of its surface.

The best of the species is V. album, and, except for the sake of variety, the others are not worthy of culture in our gardens. V. album is, however, a distinct and striking plant, and possibly, were it tender and required some nursing, it would be regarded as an ornamental sub-tropical plant. Certainly where foliage is expected to play a part in garden decoration this plant is worthy of a place; it also possesses features of attraction in habit of growth and flower. It is a native of the Alps and Pyrenees, and was introduced as long ago as 1548.

As an alpine plant of robust growth it is one of the best, and is worthy of a place on bold rockeries, and rooteries, and rustic mounds. It will also flourish admirably in the open border, and is suitable to plant at the front of shrubberies. It will grow in any soil, but to flourish to perfection it should have deep rich loam, such as Rhubarb delights in. It will then grow to a height of 5 feet, and its bold white spikes are decidedly ornamental in the middle of summer.

V. nigrum, or the dark purple-flowered species, is much the same in habit as the preceding, but does not grow so tall, and is less ornamental; while V. viride, V. parviflorum, and V. angustifolium are destitute of attraction in the flowers, and are only interesting by their habit and foliage.

V. album, as the figure suggests, is worthy of cultivation, and is now being taken care of by those who possess the plant, but who have for a long time suffered it to be neglected. It is readily increased by division of the roots in the spring, just when the plant is making fresh growth, which is the ordinary mode of propagation. Plants may also be raised from seed.—W.

FORCED VEGETABLES IN POTS.

In the Journal of May 13th, No. 737, in the report of the Royal Horticultural Society's meeting was noticed some forced vegetables grown in 8-inch pots, and exhibited by Mr. T. Batters, gardener, Chilworth Manor. Being on a holiday recently, I paid Mr. Batters a visit, and saw the forced vegetables growing. I can assure the readers of the Journal there is no deception in the growing of these vegetables in pots. There they may be seen — Peas, Broad Beans, Kidney Beans, Potatoes, Vegetable Marrows, and Tomatoes—all growing in 8-inch pots, and they are the picture of health and fruitfulness.

Mr. Batters kindly turned out a root of Potatoes to show me, and there were fifteen good moderate-sized tubers to a single 8-inch pot. The tubers varied in size, some being very large for the space they had to grow in.

The Peas were really superb, and an excellent crop too; the variety was Maclean's Little Gem, a first-rate early wrinkled dwarf Marrow Pea, and excellent for forcing. The seed is sown about the middle of November, and when up thinned out, leaving six Peas to a single pot, of which there were fifty. They are kept in a cool vinery all the winter where frost is excluded. When it is required to keep the house at a higher temperature after the Vines have been started the Peas are removed to a cooler house, and kept as near the glass as possible, with plenty of air daily. Mr. Batters informed me he had already gathered three gallons, and at the time of my visit there were from seven to eight good-sized pods to a single haulm and averaged seven large peas to a pod.

The Canadian Wonder Beans were also splendid, being very prolific and the pods being of great length. Broad Beans were also excellent.

The Tomatoes, Orangefield Dwarf, quite surprised me. The plants were raised by cuttings struck in October, 1874, and potted-on into 8-inch pots. There was some splendid fruit on the plants, which carried a heavy crop.

The Vegetable Marrows were also raised from cuttings in October, the varieties being Custard Marrow and Moore's Vegetable Cream, the latter being the most prolific. The plants were in excellent health, and bearing abundantly. My time was very short and hurried, otherwise I should have

been able to have given a more accurate detail of the above vegetables.

At the same place may also be seen Watercress in pots, and other things in the vegetable and salad way. I hope Mr. Batters will give us a few remarks on forced vegetables, &c., some time in the Journal, as it will be very beneficial to those gardeners having but a small amount of labour, and at the same time are expected by their employers to have everything just the same as those who have greater conveniences at their command.—F. H. Froud.

[The vegetables referred to were highly creditable examples of pot-culture.—Eds.]

NOTES on VILLA and SUBURBAN GARDENING.

KITCHEN AND FRUIT GARDENS.

A few general remarks at this busy time will doubtless be of some service, and it is well to remind villa gardeners that much of their success depends not only in insuring comparative tidiness, but in the proper attention to all their crops at this time of the year; and again, while there is yet time to make up for any main crop of which there is likely to be a deficiency, it will be best to sow again at once. Therefore take care to examine all crops, and judge from their appearance whether more is required; and further, by hoeing and stirring the soil well now it destroys such an extensive progeny of weeds, and benefits the crops also, which greatly lessens the labour during the remainder of the season. If the late crops of Potatoes are not earthed up they should be at once; delay in this matter often injures them, because the small rootlets run so wide that it is impossible to mound the earth without checking their growth.

Early Celery should be earthed a little, previously pulling the suckers off if any are showing. Plant out another row for succession, and prepare trenches for the general crop, which ought to be pricked out and growing on a border preparatory to planting out. Plant another row of Scarlet Runners if room can be found for them, and earth-up and stake those which are growing fast. This crop thrives best if it is not allowed to suffer from the want of water from the time it comes up till it has done bearing. It is one of the most profitable vegetables.

Cauliflowers just coming in from hand-glasses should be well supplied with water, or the produce will be small and more quickly run to seed. Sow at once a small quantity of seed to supply an early autumn crop, and do not in finally planting out neglect to give them a rich soil, and yet they had better be in the open garden than on a hot sunny border under a wall at this season. Onions—if necessary, prick-out a lot of the best on ground previously prepared, taking care that they are not planted deeper than they were when taken up. Thin out the remainder of the crop before they become too large.

Sow a good breadth of ground with Turnips for early autumn use; it will be best, perhaps, to first decide how much ground can be spared for this crop, and then sow a portion now, and again at the end of the month. This will insure a succession which will be useful a considerable time. The seed ought to be sown in a shady place instead of a hot or sunny one. If Parsnips are not thinned out they should be at once, leaving them about 8 inches apart, and take care that the ground is well stirred between them. It cannot be done after the foliage has covered the space allotted to them. Where Leeks are grown it will be as well to prepare a place on a rich piece of ground, or make small trenches as for Celery, and prick them out at once. Another lot may follow as soon as the ground can be prepared for them.

Plant out Brussels Sprouts at once, and also Snow's and other early Broccoli, and then if ground cannot at present be spared prick-out all other successional crops on good soil, to be finally transplanted at a more convenient time. Sow at once all the different sorts of late Greens to fill up spaces that are at present occupied with other crops, but let all the most forward sorts sown in April be planted out at once.

Asparagus continues to be plentiful, but it will be best for further supply if it is not cut quite so close as formerly; this will leave enough growth to keep the roots in a thriving condition, and be an assistance to next year's crop. Beds of this vegetable lately planted must be well supplied with water and kept clear from weeds, to insure the formation of crowns and more mature growth next year. Of Peas sow more as others appear above ground. Any of the Marrow sorts may be chosen, but if there is any choice do not sow them in the hottest part of the garden, but the coolest. Very hot spots do not suit Peas for late crops.

Plant-out the smooth-leaved sort of Cabbages for an autumn crop, and take care that the Ulm and other Savoys are planted out as soon as ground can be spared for them. But it often happens that in small gardens plots are not to be found for crops of this kind; therefore, to save time and insure a regular succession of vegetables, they ought to be planted between rows of other crops, such as Beans or Potatoes, which are likely to come off soon enough to allow them the place to themselves.

Strawberries appear to be setting freely, but they must have plenty of water if the weather should prove dry before they approach ripeness. The ground between the rows should be covered with grass or clean straw to keep the fruit clean when heavy rains fall, and as a mulching to prevent a rapid evaporation after watering.

Vines on walls will now need attention, for even if disbudding has been done the shoots remaining will need stopping a joint or two beyond the bunch, excepting those needed to fill up vacant spaces, which must be laid in all their length, and all shoots should be fastened to the wall. Continue the thinning of fruit on wall trees, and go on with the nailing of all shoots that are likely to be battered about by the wind, and on trees with green fly apply a frequent syringing with weak tobacco water.—Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

Beds of Strawberries require all the attention we can afford them; the fruit has set abundantly and well, and ought now to be thinned out. First in importance is giving the plants an abundant supply of water, and as soon as the water is applied to mulch the ground with short manure. We have given each plant about two gallons of water, and the mulching will retain the moisture. We shall, when the fruit has swelled a little more, support the trusses with sprays or small branchlets of elm and hornbeam that were prepared in the winter. This is the best way to keep the fruit clean, and it allows it to ripen better by allowing the sun and air to play freely around it. Those who cannot obtain these sprays will find a row of ordinary bricks either laid on edge or flat to be a good plan to preserve the fruit. It will lay on the bricks or hang over the sides. The porous material absorbs the heat, and gives it out slowly at night. Clean wheat straw laid between the rows answers very well, especially in dry seasons; but if it should be a wet season the fruit soon decays if not gathered as soon as it is ripe. The mowings from the lawn, tan, and cocoa-nut fibre refuse have all been recommended to be placed between the rows to preserve the fruit. Tan is the best of the three, but in some cases it would be better to allow the fruit to rest on the ground than to use either of them. The particles stick to the fruit, and cannot be removed without bruising it. All the runners will not be required for the purpose of increasing stock or for pot plants; when this is so only the runners required should be retained.

Newly-planted trees ought to be watered, and the ground over the roots mulched. If they have not started, freely syringing them night and morning will still cause some of the backward growths to push. Those who have had experience in planting fruit trees will have observed the buds start freely enough at first, and after a while they stop growing; this is the time to apply water to the trees from a syringe, and also to the roots if required. Mulching with rotted manure is also indispensable to keeping a moist equable temperature at the roots. The trees should also be securely staked.

Vines are not generally grown as wall fruit, but many amateurs and cottage gardeners have them on low walls. Sometimes they are well managed, at other places badly. In the south of England very good Grapes can be grown on walls facing south, south-west, or even on west aspects; but they always give the greatest satisfaction if plenty of young wood is trained up to supply the place of the old stems. The best system of culture is to train a rod horizontally right and left from the main stem about 9 inches or a foot above the surface of the ground. From these horizontal branches the young rods must be grown annually, providing the walls are low (good Grapes can be grown on walls 6 feet high); but on lofty walls it is not necessary or even desirable to renew the rods every year; but they may be renewed every third or fourth year, gradually laying in young shoots and taking out old wood, so that a steady renewal is constantly going on. The best Grape for open wall culture is the Royal Muscadine, but in favourable positions Black Hamburgh ripens, and even tolerably good Lady Downe's and Muscat of Alexandria have been produced. The Vine on the open walls is generally free from insect pests; but red spider will do mischief in hot dry seasons, and must be removed by syringing.

The larva of the lackey moth is now busy on the fruit trees; the webs forming the tent in which they lodge at night or in inclement weather are easily discerned. The pest ought to be destroyed when they are all clustering together. We have also noticed the Apple-boring maggot at work on the fruit that has just formed. If practicable the fruits attacked ought to be destroyed at once. The crop of fruit is so abundant that two-thirds might be removed. The Plum trees are free from aphis, and have a good crop of fruit; in all other respects all the trees are healthy.

VINERIES.

When the fruit is ripe the object of the gardener is to preserve it in good condition. If the weather is hot and dry the berries

soon show signs of shrivelling. This may be prevented by sprinkling water on the paths and borders of the house; it may also be necessary to water the roots. It is a very great evil indeed to allow the inside border to become too dry. All the time that the fruit is ripening, and hanging after it is ripe, the young growths are also ripening, the wood is being consolidated, and the buds from which will spring the future growths are being formed and matured, and this will not be done effectually unless a plentiful supply of moisture is sent up by the roots.

We have nearly finished thinning the fruits in late houses, but where little artificial heat has been applied it will now be time to see to the setting of the fruit. With the free-setting sorts there is no difficulty; but shy setters, as Royal Vineyard, Lady Downe's, Snow's Muscat, &c., the bunches should be gently shaken about 10 A.M. daily during the flowering period. A globule of moisture gathers on the stigma of some of the sorts, and this is removed by drawing the hand gently over the bunches, and assists the setting of the berries. We do not pinch off any lateral growths during the time the fruit is setting, but when the Grapes are set the laterals are pinched back and tied down to the wires, and the border receives a thorough soaking with manure water. In ten days or more after the first flowers open it will be time to commence thinning the fruit.

ORCHARD HOUSE.

We are thinning the fruit of all the trees, Peaches, Nectarines, Pears, Plums, and the finer varieties of Apples. We have from four to six dozen fruits from Peach and Nectarine trees in 15-inch pots. The trees ought not to carry a larger number than this, and if handsome exhibition specimens are required, three dozen Peaches and four dozen Nectarines will be a sufficient number. The growths are now stopped, and if too thickly placed they are thinned-out. The trees, and Strawberries on the shelves, are thoroughly syringed twice daily—in the morning at six, and in the afternoon about five. The pots are abundantly supplied with water, and about the middle of June the first dressing of manure will be applied to the surface of the pots.

GREENHOUSE AND CONSERVATORY.

There is now plenty of work in this department. Flowers do not last long in beauty at this season, and frequent alterations are necessary to keep up the display of bloom. Azaleas that have not been forced are now in full beauty. The plants must be shaded from the sun, and the house be kept as cool as possible to prolong the beauty of the flowers. Those plants that have flowered are removed to a warmer house to make their growth. They would not flower freely next season if they were allowed to make their growth in a closely shaded cool house. The shading ought to be fixed to rollers, so that it can be rolled up or let down at pleasure; it is a great mistake to fix a permanent shading to the roof, as the more light the plants receive the better.

Stage Pelargoninms, including the Fancy section, are now in flower. The Fancy varieties have not been so popular as usual, nor have the large-flowered sorts received that attention their merits deserve. Show Pelargoniums do not seem to be acknowledged by the "Pelargonium Society," nevertheless both sections are invaluable at this season of the year.

Roses are now very beautiful under glass. The decaying flowers must be cut off as soon as the petals are bleached and hang about loosely. The flowers ought not to remain on the plant until the petals drop off. The remarks last week by Mr. Camm on scented Roses were very opportune. Shape, substance of petal, and quality of the flowers have all taken precedence of the perfume. Now, with a very large number of Rose-growers scent is placed first, the other qualities after, and the aim of all the raisers is to obtain the best sorts for exhibition. Mr. Camm should add Bessie Johnson to his list of perfumed Roses, it is the sweetest in its class. As the flowers die off the plants are removed to a sheltered position out of doors.

Aquilegias are not much grown for greenhouse decoration, but some of the species are well adapted for this purpose. A. pyrenaica, A. leptoceras lutea, A. glandulosa, A. alpina, and A. coerulea if well grown are very handsome, and make an excellent change, as the colours are quite distinct from the everlasting zonals with which we are being overdone. Go where you like, in every garden large and small, in flower beds and in greenhouse, masses of flaming scarlet dazzle the eye, and it is a great relief to turn for a little to more quiet colours. The potting material for the different species of Columbine should be turfy loam, with a little leaf mould added. The plants must also be syringed frequently to keep red spider in check. See that no plants suffer for want of water. Tie and train all climbers about once in a week or ten days.—J. Douglas.

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Leeds.—June 9th, 10th, and 11th. Mr. J. Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.
Burton-upon-Trent.—June 16th. Mr. Wm. Shave, Bond Street, Sec.
Jersey.—Rosea June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon.-Sec.
York.—June 16th, 17th, and 18th. Mr. Jno. Wilson, 13, New Street, York, Sec.
Glasgow.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.
Exeter (Rose Show).—June 18th. Mr. J. N. Gray, Queen Street Chambers, Hon.-Sec.
Fareham.—June 23rd. Mr. H. Smith, Sec.
Stowmarket.—June 24th and 25th. Mr. S. Prentice, Hon.-Sec.
Reigate (Rose).—June 26th. Bushby Britten, Esq., Hon.-Sec.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Hothouse Grapes, &c. (*E. Lowther*).—Write to Messrs. Webber & Co., Centre Avenue, Covent Garden Market.

Variety of Oak Gall (*A. R., Bromley*).—The twig of Oak sent is attacked by two kinds of Gall flies, Cynips quercûs pedunculi, *Linnæus*, which makes currant-like galls, and C. quercûs ramuli, which makes woolly galls. They are not common.—I. O. W.

Fly on Gooseberry Trees (*J. C.*).—The fly sent is one of the Saw flies Nematia ribis or ventricosus, the larvæ of which will very shortly be hatched from the eggs laid on the under side of the leaf. They are very voracious, and if not hand-picked and destroyed will defoliate your trees.—I. O. W.

Strawberries Unfruitful (*R. B. N.*).—The plants which have not any flowers, and consequently no fruit, we should not allow to cumber the ground, but at once clear them away, and crop the ground with vegetables. A new plantation of Strawberries should be made so early in July as you can obtain rooted runners, which may be secured earlier by pegging the runners, or they may be laid into small pots, and when well rooted detached and planted-out. Runners from fruitful plants only ought to be taken.

Pruning Laurels (*H. G. M.*).—As they were partly pruned in January you may, now they are breaking freely, cut them in to the required form, but those cut in January will take the lead, the others starting away also freely at a later period. Sweet Baya may also now be pruned, but it is better done a month earlier, as the growths being made late do not ripen well, and are liable in a severe winter to have the unripened wood injured.

Fly—Seakale Planting (*E. M. P.*).—The fly is not injurious. In planting Sea-kale for blanching by pots and litter, &c., it is usual to plant three plants in a triangle, so that they may give a good supply of heads from a pot; but though we practise this, and advise it, there can be no doubt single plants will from the greater distance give larger heads, and will in time have as many crowns as it is desirable to have shooting up under one pot. It is easier, however, to thin than to produce, besides having to wait two or three years for that which may by planting three plants be had from the first year after planting—viz., a maximum of produce for the means employed.

Grapes for Market—Planting Vines (*E. P. N.*).—The most profitable Grapes are those which are ripened at a time when they fetch the highest prices, and this is in spring after the old Grapes are gone out, when they may bring in May and early June 5*s.* per pound. To have them in August, September, and October or November is to compete with foreign produce and home easily-cultivated products, the prices then being at a minimum, and to have late Grapes keeping in good condition up to April is perhaps the most profitable of all. You will need to bear in mind the difficulty and increased cost of production of Grapes ripened in May, and late ones ripened in August to hang until March over those grown in summer mainly by natural heat. We give you the Vines that will answer the several purposes—viz., for early forcing—Black Hamburgh, Foster's Seedling, Mill Hill Hamburgh, Bucklaud Sweetwater, White Frontignan. Summer—Black Prince, Duke of Buccleuch, Frankenthal, Black Hamburgh, Madresfield Court, and Buckland Sweetwater. These will succeed with very moderate artificial heat. Late—Muscat of Alexandria and Madresfield Court. Those may be useful if you wish to have some to cut in autumn, they not being good hangers after November; and for very late—Alicante, Barbarossa, Lady Downe's Seedling, and Mrs. Pince. Whatever class of Vines you have, arrange to have them planted inside, the front wall having openings 2 feet wide, and 14-inch pillars between of masonry for the support of the front. Your house will accommodate eight Vines at 45 inches apart, and, considering its narrowness, we think you will succeed best by growing summer Grapes. Planting is best done in spring when the Vines are beginning to grow.

Melons not Setting (*Subscriber*).—Probably a very free growth, induced by a close and moist atmosphere with deficient bottom heat. The best aids to setting we know are a brisk bottom heat, the shoots not overcrowded, free ventilation, a moist state of the soil, but a dry surface and atmosphere, and a little air at night so as to prevent moisture condensing upon the flowers. Impregnate the flowers upon a fine day when a sufficient number are expanded, and stop the shoot of each at the same time one joint beyond the fruit. Melons have set remarkably well with us this season.

Removing the Leaves of Hyacinths (*H. G. M.*).—The leaves ought not to have been removed until they had begun to turn yellow. By cutting them off short whilst in a green state the growth will be stayed, and the ripening of the future growths impaired.

Pruning Chimonanthes fragrans (*Idem*).—Cut it in after flowering, removing the old and bare wood, but preserving the young parts, or prune in as to originate them early in the season, so that the wood resulting may well ripened.

Lavender Culture (*S. E.*).—It is prepagated by slips or cuttings of large pieces inserted in the ground early in April or in September, inserting them up to the growing parts, and firmly, in light soil in rows 2 feet apart, and the slips 1 foot asunder, watering it dry weather prevail. At the end of June or early July the flowers will be ready for cutting for drying or distilling, and after the removal of the flowers the plants should be cut-in, leaving about an inch of the present year's growth, from which will be produced the growth giving the crop of flowers the season following.

Wild Celery.—"The Droitwich Canal, which for the six miles of its length is slightly salt, is bordered by Celery, which has exactly the appearance and smell of the cultivated plant. If plants were removed from its banks and cared for in a garden, may they be safely used for culinary purposes?" It is the Smallage, or Wild Celery, Apium graveolens. If planted in a garden and blanched it might, perhaps, be eaten without injuring the eater, for it is the parent of our garden Celery, but it is so strong-smelling, acrid, and fatal if eaten when at all green that no one should venture to eat it. Celery plants and Celery seed are cheap enough.

Pelargonium Flower (*Jack*).—The markings, white streaked with crimson, are rather novel.

Pansy Seedling (*C. R. S.*).—The petals are the darkest we have seen being almost black.

Caterpillars on Gooseberry Trees (*W. B. H.*).—Dust the leaves thoroughly with white hellebore powder. Next day syringe them until all the powder is washed off. If any caterpillars survive, dust again and syringe as before.

Pear Leaves Black-blotched (*E. D. L.*).—The root action is deficient. Water copiously with weak tepid manure water, mulch over the roots, and keep the mulching on throughout the summer.

Hollies Unfruitful (*J. W. S.*).—The sprays sent are from a barren tree. The flowers have stamens but no pistils, therefore cannot form fruit. Some trees are always barren, and others, as in other fruit trees, occasionally bear fruit. By no treatment can such flowers as those you enclosed be made to produce berries.—G. R. Allis.

Double Gorse (*G. T.*).—The simplest way to raise plants in quantity is to put in slips or cuttings closely in rows in the autumn. A sandy border under a north wall is the best site. The cuttings may be 6 inches in length, and be put in firmly to a depth of 4 inches. They will also strike at the present time if put in sandy soil under handlights and duly shaded.

Vines Scalded (*R. A. W.*).—Your healthy Vines have sustained a chill and a scald. A low night temperature has caused a condensation of moisture on the foliage, and a close atmosphere in the early morning has completed the mischief, but it is not serious. The minimum temperature should not be below 55°, and 60° would be better, with the top lights opened an inch all night, increasing the ventilation at 6 A.M. in bright weather, or as soon as the thermometer has risen 5°.

Geranium for Exposed Situation (*N. B.*).—Lucius will probably suit you; but the situation is about as unfavourable as can well be. Vesuvius in such position we have found useful.

Vine Canes Splitting (*Thos. Nicol*).—The splitting of the bark is nothing unusual, and you have nothing to fear on that account, as it is no more than the rupture of the outer bark, owing to the expansion or growth of the canes. The white spots or dots are as you presume a good sign, the whole appearance as described by you being evidence vigorous health.

Hardy Plants for Cut Flowers (*G.*).—Amaryllis Athamesca, Antirrhinum majus vara., Astragalus vaginatus, Azalea procumbens, Bambusa japonica variegata for its foliage, Campanula aggregata, C. lactiflora, C. macrantha, C. rapunculoides; Cardamine pratensis flore-pleno, Centaurea phrygia, Cheiranthus longifolius, C. Cheiri (Wallflower in variety), Convallaria majalis vars., Coreopsis auriculata, Cyclamen coum, C. hederæfolium, Dactylis glomerata variegata, for foliage; Delphinium alopecuroides, D. Belladonna, D. Keteleeri, D. William Pfitzer, Dianthus cruentus, D. floribundus, D. fragrans; Pinks, Carnations, Picotees in variety, Dictamnus fraxinella, Dielytra spectabilis, Epimedium pinnatum elegans, Epilobium rosmarinifolium, Erianthus Ravennæ (Grass), Hemerocallis flava, Hyacinthus amethystinus, Hypericum calycinum, Iberis Garrexiana, Iris germanica vars., I. Kæmpferi vars., Lathyrus grandiflorus, Leucojum vernum; Lilium auratum, candidum, lancifolium; Lobelia fulgens St. Clair, Lychnis diurna flore-plene, L. viscaria flore-pleno, Myosotis dissitiflora, Narcissus conspicuus, N. Ajax, N. angustifolius, N. incomparabilis, N. juncifolius, N. poeticus and var. flore pleno, Nepeta Musaini, Pæonia in variety, Pentstemon in variety, Phlox in variety, Primula acaulis vars., P. cortusoides amœna, P. japonica, Pyrethrum double vara., Ranunculus amplexicaulis, Rhododendron hirsutum, Rosea, Saponaria caucasica flore-pleno, Saxifraga longifolia, S. palmata, Sisyrinchium odoratissimum, Spiræa filipendula plena, S. japonica, S. palmata; Statice latifolia, Stipa pennata (Grass), Gynerium argenteus (Grass), Thalictrum minus, very nicely divided, not unlike Maiden-hair Fern; Trollius europæus, T. napellifolius, Veronica prostrata, and Violets in variety. Those are all hardy herbaceous plants. *Annuals* are:—*Abronia umbellata, *Ageratum coeruleum, Alyssum maritimum, *Aster Victoria vars., Calliopsis Burridgi, Centaurea cyanus major and minor, Chrysanthemum Dunnetti flore-plene and double golden variety, Helichrysum var., for dried flowers for winter bouquets; *Marigold, French (some object to the smell), Mignonette, Nasturtium Tom Thumb vars., Sweet Peas, *Phlox Drummondi vars., *Scabious, dwarf double; Senecio elegans, double var.; *Ten-week Stock vars., and Sweet Sultan vars. Those marked with an asterisk require to be treated as half-hardy annuals. Grasses a few are—Agrostis argentea, A. nebulosa, Anthoxanthum gracile, Briza geniculata, B. maxima, Brizopyrum siculum, Eragrostis elegans, Paspalum elegans, Pennisetum setosum, Piptatherum Thomasi. *Ferns*—Adiantum pedatum, Asplenium Adiantum-nigrum, Athyrium Filix-fœmina vars. Applebyanum, plumosum; Cystopteria fragilis, Lastrea dilatata cristata, Polypodiums, Dryopteria, Phegopteris vulgare, Polystichum angulare cristatum, gracile, and Grayi.

Insects on Pinus Pinsapo (*R.*).—The mass of insects found in thousands smothering the "branches inside" your Pinsapo are the largest species of Aphidæ (Aphis Laricis). They must be attacked by the usual modes of destroying plant lice.—I. O. W.

Insects on Pear Leaves (*Idem*).—The brown objects found on your Pear leaves are the moveable cylindrical cases formed and inhabited by the caterpillars of a little moth (Coleophora Hemerobiella). We know no other remedy than hand-picking.—I. O. W.

Names of Fruits (*B. S. Williams*).—Adams' Pearmain. (*M. Webber & Co*).—We are sorry we cannot name the French Apple you have sent.

Names of Plants (*K. T.*).—1, Ranunculus parnassifolius; 2, Orobus vernus. (*Ten-years Subscriber*).—1, Euphorbia Paralias, *L.*; 2, A Willow (Salix sp.). (*G. Floyd*).—Sparmannia africana. (*M. M. B.*).—Mesembryanthemum sp. (*O. P.*).—Ligustrum lucidum. (*W. Heard*).—Apparently rightly named, and a very fine specimen.

POULTRY, BEE, AND PIGEON CHRONICLE.

SHOW MANAGEMENT AND REPORTS.

The exhibition season is once more upon us. The two or three months of rest which always come early in the year are over, and the list of forthcoming shows promises us a merrier time than ever. The Crystal Palace rival has already arranged the dates for its exhibition, and the fixtures for the three last months of the year promise us an unusually lively season. To those shows we look forward with much pleasure, for we are assured that it is the early shows only which will be inconvenienced by the past disastrous chicken-tide, and that the later shows will be as strong and hot as ever. The exhibitions, however, for the next three months are many, and forewarned being forearmed, we will at once say a few words on matters connected with our shows. We will begin at the beginning and go through some of the various points in rotation.

First, then, about labels. They now range in size from pieces of linen as large as cabbage leaves to atoms of parchment. We had a label sent us the other day from Devonshire on which literally there was not room for the return address. The very large labels are as ridiculous as very small strips. We should like to see uniform labels used everywhere—labels of strong make, useful size, double-holed for tying the strings, and, above all, the direction to the show very clearly printed on them, with the name of the county printed as well in every case. Then, the labels should be sent in good time, at least four or five days before the show. Many exhibitors write from their places of business, and may be miles from their poultry-yards, and consequently they have to forward to their managers the labels. But as it is they often never come to hand till the last morning, when it is frequently too late to send them on, and all kinds of unpleasant mistakes are the results.

The detention of the birds on Sundays we have before alluded to, as, too, we have to the great importance in announcing who the judges are to be. We have not alone done this, other journals have also urged the importance of it, and other pens have taken the matter up, but without, we fear, much real success, for among all the goodly lists of shows-to-be, not a tithe of them state who are to award the prizes. We cannot conceive how the committees can be so short-sighted, for we are certain no exhibition can be a real success where the judges' names are not announced. We shall not be content either with merely knowing who they are to be, we shall not rest quiet until we may also know who are to judge the different classes.

Then about catalogues. This really is a great grievance, and a growing one. It is one of the few things in the poultry world that has not changed in some way for the better of late years. Often and often we have sent for a catalogue and the stamps have been lost altogether; anyhow, the catalogue has never come to hand, and we certainly cannot name a score of shows last season where we had the catalogues on the proper days, and often, especially from the north, when they did come they came without a prize list of any sort, and were consequently perfectly useless. Now, Secretaries, do improve on this! do try and let this coming season be marked for an improvement in this respect. Charge two or three pennies more for a catalogue if you like, to enable some one person being paid to see they do leave by the first day's post.

Next, for the flooring of the pens. We sometimes see sawdust, which is simply destruction; and sometimes sand, which is quite useless, for it only soils the plumage of the birds and gives no exercise. At the Palace we see nice shingly grit, but even this wants a layer of chaff on the top. Let us always have some coarse clean gravel, and then a good sprinkling of chaff over that. This put in fresh every morning would enable a bird to go home as clean as when it came, and very little worse for its incarceration; and then, too, every day a leaf or two of lettuce or some vegetable food should be given. It is surprising how the birds look forward to it, and the good it does them. At Oxford they give this green food, and it is an acknowledged fact that the birds go back from that Show in most brilliant condition.

Double baskets, too, we must say a word about. We call them "The 1874 Success," and greatly to be thanked is that gentleman who untiringly urged the introduction of the system, and in so many cases won the day. Go on with it, committeemen! Frequently, especially at single-bird shows, allowing the use of double baskets will double your entries. So do not forget, on any account, to add that as a new rule to your schedules. We had to do with an exhibition lately which sanctioned this arrangement, and it greatly lessened the work of the attendants, which is an important point.

A word also on the treatment of birds on their arrival. It is imperative that the water tins should not be full when the birds first come, as they are so often—filled, of course, in pure ignorance by some attendant who knows about as much of an exhibition Dorking as he does concerning an exhibition elephant. Sooner let them be empty than full, for the birds as soon as ever placed in the pens drink up the water, and black combs and swollen crops are the result. Let, then, the tins be a quarter, or at the most a third full, and let the birds have rather a sparing feed of well-mixed ground oats or sweet barleymeal. There have been during past two or three seasons so many disastrous results from injudicious feeding on the arrival of the birds at shows, that we do hope this matter is now generally better understood.

As regards allowing exhibitors or their managers to pen their own birds we would rather not say much. We know it is delicate ground, but we abstain from treading upon it, knowing it will be a perfect impossibility to please all. Perhaps on the whole we think there is not any harm in allowing it, provided there be plenty of committeemen or authorised people to go round as well and see the birds penned; but whether shows do it or not, all we do say is, Let one and all be treated alike. Let us hear nothing of Mr. Amicus being let in and Mr. Hostis being kept out. That proceeding will never do, and naturally makes the locked-out ones and others feel suspicious.

And then, lastly, we come to the reports of poultry and Pigeon exhibitions. Captain Talbot wrote a letter on this subject a few weeks ago, and sent it whirling round the poultry journals, but we do not believe that one line has ever been written in reply. This must have arisen either from the poultry world objecting to its being so much of a circular; or else they are, and this we think much the most probable, resting on their oars, thankful beyond expression for the copious and able criticisms they are now enjoying. There was doubtless an immense deal of truth in all Captain Talbot wrote, but we are quite sure that it would be an impossibility to find anyone to report systematically on our poultry and Pigeon shows who was quite disinterested. We could not name half a dozen competent people who would thus be able and willing to undertake the work. There are very few men that attend our shows but do so either because of their own birds or those of friends. We believe ourselves all the reports are sufficiently near the truth for all practical purposes, for if we read the various reports of shows in the different journals they agree in the main points. As a gentleman told us the other day, take them *cum grano salis* and they will do very well. If this Journal, or any other one, was often wrong in its criticisms, and appeared to treat some exhibitors more favourably than others, the result would be ruin, and so we think that critical comments on birds and show management must be square in the long run.

If we were to have our judges write also the reports systematically—we say systematically because no doubt some judges do at times send notes on the shows they award the prizes at, and these notes are duly prized and valued, for most attentive readers of the papers can "twig" the different writers' articles and notes though signed with a *nom de plume*. Well, we say, if the judges were also the reporters we might perhaps see more careless judging. The criticisms to which their awards are subjected by one and another have no doubt a wholesome if not a pleasant effect on them, and we should be sorry to see this relaxed in any way. Captain Talbot suggested that the reporters when exhibitors should sign their names. This is not a bad idea, but even this is of no real use, as very few are qualified to form a correct opinion about every breed at a large show, and where their knowledge fails they generally get some friend who is up in the breed to lend a helping opinion. No, we think for the most part the present reporting system is very good, and cannot well be improved upon. We recommend, however, exhibitors and others not to adopt an hasty conclusion as to the authorship of different reports, for this may bring trouble upon them. We ourselves know of one gentleman who happened to hear that a certain party was at times wont to send notes on shows to this very Journal. Well, this gentleman, whom we will call Mr. A, met the other party, whom we will term Mr. B, at three or four shows. Mr. B was himself an exhibitor at those shows, and on each occasion won the first prize or cup in severe competition, and his pens were consequently lauded, not only in this Journal but in others. Mr. A having seen Mr. B at the shows immediately put two and two together and tried to make five, for he set about the report that Mr. B had written the reports himself, and eulogised so highly his own specimens, when as it happened Mr. B. had never written one single word of the said reports.—W.

Bramley Show of Poultry, &c.—We have received the schedule of the fourth annual Show to be held at Bramley in Yorkshire. In all sections the prizes are 15*s.*, 7*s.* 6*d.*, and 2*s.* 6*d.* For poultry there are twenty-two classes, one silver cup and a water fountain being offered as extras. In Pigeons are twenty-one classes with five extras—viz., a cup as one, a pair of Pigeons as another, a Batty's water fountain and bath combined, one silver medal, and a Batty's self-feeding hopper—useful articles, we are glad to see, in lieu of the ever-recurring cup. In Rabbits there are eight classes, with an extra 10*s.* for Lops and two boxes for the other breeds. Cage Birds having also eight classes, with a six-holed breeding cage, and a cage cathedral-shape as extras. The schedule is a good one and we commend it to the notice of our readers. The Judges are (as in all cases they should be) announced on the schedule. They are Mr. E. Hutton and Mr. W. Cannan.

BATH AND WEST OF ENGLAND POULTRY SHOW.

We only had one spare day this week, and we wanted to spend that day in a proper sort of manner. We had a long debate where we should go to; for we wanted to see this Society's meeting, we wanted to see the dogs at the Palace, and we wanted to see the horses at Islington—in fact we wanted to do everything. It was an *embarras de richesse*, and we did not know which promised the best. Mr. Goodwin and his troupe we knew; we met them many years ago at Salisbury, and we have since visited their leviathan meetings annually. We have heard the cocks crow at Taunton, and Guildford, and Plymouth, and goodness knows where besides, for this Society is very erratic in its movements, and strides from Somersetshire to Surrey in one bound.

> "With thymey breath and bees that hum,
> Across the years it seems to come."

But old loves are the true loves, and so to the old love we adhered, and Croydon was the chosen one out of the three dainty dishes. And when we got there—why, it did seem like old times. We could almost have fancied that the whole concern had been packed up last June on the Clifton downs, labelled "This side up with care," consigned to Croydon, and there unpacked again. It all seemed identical. The tents, the flags, the stalls, the very people's faces all seemed the same, and everything looked if possible brighter than ever. We may safely say to this Society—

> "Where'er you go, where'er you pass,
> There comes a gladness o'er the grass."

Yes, we were indeed glad we chose Croydon. We should have been sorry to have neglected this old love in its time of mirth. It was truly pleasant to walk among the old familiar things. We saw ploughs and carts painted as bright as ever. We saw cucumber-cutters, pea-shellers, potato-mashers, all working away as if they had never stopped since last year. We saw what appeared to us the same imitation-marble mantel-pieces, grouped as if they were going to have afternoon tea together, with impossible-looking Ferns and fruits growing upon them, vainly trying to look natural. We threaded our way past bright pink pigs and sleek Alderney cattle, past cattle foods and poultry condiments. We walked through conservatories and greenhouses. We gazed at marvellous wirework manufactures, and saw turnip-cutters working away like steam-engines. It was, however, like going from London to Cambridge to get to Oxford, such a way round it seemed; but at last we heard the welcome sounds, and the poultry tent was close at hand. As we entered it, and gave one preliminary peep round, we felt we should take even a still greater interest in this our favourite department had we not remembered that the "Sunday detention" was here in force. But we have alluded to that before in these pages concerning this Society, and will do so no more, hoping that before another year comes round someone will try and arrange it differently, for—and we speak advisedly—we can name no less than seven former patrons of this Society's poultry shows who have not exhibited this year because they will not countenance this Sunday business. We must say a word, however, to condemn the soft food upon which the poultry were fed. It more resembled barley chaff than barley meal, and the birds did not care for it at all. Then, too, we walked from pen to pen among the Pigeons, and nearly every water tin was empty and most of them full of dirt. Such things should not be at a meeting of such fair fame as this Society enjoys. It was a long while before all the prize cards were up. When we left at 4 P.M. on the first day some of them were still not put up; and considering the birds—poor creatures!—had to be in on Saturday, there really was no excuse. The Judges were Messrs. Tegetmeier and Harrison Weir, and we saw ourselves the great trouble they took over the awards, and if they were not all quite satisfactory we must remember the immense labour they had, for there were 530 pens, and those mostly above the ordinary quality. Most certainly the Committee, when they saw the large number of entries they had, should have engaged the services of another Judge to help, for it is as unfair to the Judge as to the exhibitors for one man to have so much work to do in a short time.

Spanish came first on the list, and the two classes brought thirty-seven pens. The quality was splendid, most of the Bristol fanciers exhibiting. The cup-winner was a grand cock,

and so was the second-prize bird. 17 (Mills) a most beautiful young bird, and worthy of a notice certainly. The hens were also a good lot. We liked the second as well as the cup pair, still there was not much wrong. 33 (Woodhouse) a capital pair, and so were 28 (Chilcott).

Dorkings again made grand classes, all the varieties mustering well. The cup Coloured cock was a beauty; he was immense in size, and good all round. The second, too, was a grand bird; one toe was a shade swollen, but he deserved his place, and was a good second. 52 (Rice) a good bird. 48 (Cork) large and nice in shape. In hens the cup pair were superb in condition and of huge size, though hardly matching in colour. Second were also in grand order, and a splendid pair of hens. 72 (Hodges) a nice pair. 63 (Darby) fine well-shaped birds, and of good colour, but smaller than the winners. Silver-Greys were two small but good classes. Mr. Cresswell brought a fine team, and should have had, we fancied, all four prizes, for we preferred his 75 to the second-prize bird, the latter having a swollen toe. The Silver hens were very fine and in good condition. White Dorking cocks were poor; they were so very yellow, or else the first cock was large, and good in comb and tail. The first hens were very fine and well shown. The second prize went to Cuckoos, a prettily-marked pen. 91 (Darby) had one splendid White hen, but her companion was not equal to her. 96 (Putney) a neat pair of Cuckoos.

Cochins came next. There were nineteen Buff cocks. The first was in beautiful condition and nice in colour, but rather small. The second we did not care for so much. 97 (Alsopp) a fair bird. 104 (Darby) a grandly shaped and feathered cock, but too light. 102 (Harris) disqualified for broken tail feathers. The Judge assured us he always meant to disqualify for broken tail feathers in Cochins. We certainly think at this time of year especially that broken tails should have the benefit of the doubt, for they are more probably the result of being confined in a breeding pen than of being designedly tampered with. In this case we have seen the bird winning on many former occasions with a splendid tail; but the Judge took him as he was and disqualified him. The hens were not a good lot. The first were rather destitute of leg feather, and rather white in the leg. Second a fair pair. Partridge cocks were only middling. The winner had a very full tail, but was in nice order. Second a good bird. There was only one pair of hens, and (*miserabile dictu!*) these also had left their tails behind them, and were disqualified. We could not help smiling at this, for their tails had disappeared entirely, and a great many back feathers also, and this is not the way Cochin hens are generally "faked-up." White cocks were good. The winner was the only white bird in the class; he had splendid hackles and fine carriage. The second was very hocked and very yellow. We much preferred 135 (C. Bloodworth). 143 (Burnell) the yellowest cockerel we ever saw. The winning hens were large and good in shape, but rather bad in comb, still a good first. For second we should have gone to 147 (Boissier) or 148 (Warde); the latter pen contained one fine hen.

Dark *Brahmas* made two large classes. The first was in lovely condition and well first. We hope by seeing Mr. Lingwood's name again in the catalogue he has recovered from his late illness. Second a small but pretty bird. 149 and 150 (L. Wright), two nice cockerels, but they wanted a little more leg feather; they were well shown and in splendid condition for the season. There were one or two pens in this class we liked as well as the second-prize bird. The first hens were well marked and nicely feathered, as too were the second-prize pen. Light Brahmas were very fair in quality and good in quantity. The first was well placed. 186 (Savile), we liked better than second. One or two more birds should have been highly commended in our opinion. 178 (Long), good; 180 (Boissier), ditto. In hens one of the first-prize pair was very grand, large, and heavily feathered; but her companion matched so badly that we should have been inclined to put the second-prize pair over their heads. 194 (Haywood), a lovely pair of early pullets, the earliest we have yet seen this season.

Game were very good, and most of the best yards put in an appearance. In Brown-breasted Red cocks we thought the best bird was left out—viz., 233 (Matthew). The second-prize bird was not nearly equal to him, and the first looked suspiciously round in the back. The first Duckwing cock was an easy win. 248 (Winwood), out of condition. The first Duckwing hen was a beauty.

Hamburghs mustered pretty well. The winning Gold cocks (Spangled), were good. In hens, 270 (Beldon), were in best feather, and we should have liked to have seen them higher. The second Silver-spangled cock must have been a mistake, it had such bad ears, its neighbour, 273 (Beldon), being much superior to it. The first-prize bird had splendid wings, and was well first. The Silver-spangled hens did not match well. A grand pair could be made by taking one from each pen. The Golden-pencilled cocks were good. The second was in best condition. In the Golden-pencilled hens one was much superior to the other. The second were a good pen. In Silver cocks Mr. Beldon walked his winner in, and so he did his pair of hens Second hens a neat pair.

Polands were two grand classes. We were glad to see so many good White-crested Blacks. The first in both classes went to grand pens of Silvers, and second to Blacks. 300 (Bloodworth), a good Silver cock.

Houdans were good. The first cock a beauty of good colour and fine carriage. 321 (Dring), a splendid fellow, and was, we believe, first at Birmingham, but here unnoticed. The Houdan hens were good and in fine order. *Crêves* were splendid. The first cock very good all round. Second a nice bird, but we almost preferred 333 (Fowler). The first Crêve hens were very fine, but we liked 341 (Dring) next best to them; had they more crest they would have been higher we conclude, for they were very large and good.

The Variety classes were large and varied. First in cock went to a fine La Flèche. Second to a Black Indian Game in grand condition. 352 (Beldon), a good Black Hamburgh. 348 (Fowler), a pretty Leghorn. White Minorcas won first in hens, a fine pair but looking very antique, and second went to Blacks Minorcas. 364 (Kitchin), nice Brown Leghorns.

Aylesbury *Ducks* were only three pens in number, but the winners were good. Rouens were rather out of feather, still they were well judged. The Variety class only had three pens. in it also. *Turkeys* were good, the winners really fine birds. Mr. Fowler's winning *Geese* looked as grand as ever, and would have won in any company.

Bantams were good, but there were only two pens of Sebrights: wherever was Mr. Leno? Blacks were good and numerous. Game were all huddled into one mixed class, in which it must be impossible to pick out the winners to give satisfaction to all.

Pigeons mustered about one hundred pens. Mr. Fulton and Mr. Cresswell came to the front well. The first *Carrier* cock was a grand Black. In hens the winners were both Duns, two capital hens they were too. In *Pouters* there were but four entries, and Mr. Fulton owned the lot. *Runts* were good; very fine silver Duns first, and nice Blues second. In *Dragoons* a Blue and Dun were first and second respectively. *Fantails* were a charming class, the winners lovely. 469 (Dickinson), a very pretty pair of Yellows. *Archangels* were middling. We have seen the first-prize pair before, and in better condition then than now. *Turbits* were beautiful, the first-prize pen perfect gems. In *Tumblers* again Mr. Fulton walked his two pairs over, for there was nothing to come near them. *Nuns* and *Owls* were only fair. The winning *Jacobins* good; the first a very beautiful pair of Reds. A pretty collection of fancy Pigeons in the Variety class completed this department, and on looking back on past shows we do not hesitate to say that on the whole the show of poultry and Pigeons this year has surpassed those held for the last five or six seasons. The improvement too being especially observable in the useful classes.

The Bath and West of England has never in my recollection been in Bath, though it is to come, and also with a like delightful contradictory spirit has moved from the west, for it is held this year at Croydon, which means London, and London we all know is nearer the east than the west. But that is not all its feats; it has jumped over the back of "the Hants and Berks," which I hope, however, will not "duck and go under," for the Hants and Berks, though smaller than the Bath and West of England, is still beautiful for its size. But though I wonder a little to find my old friend B. & W. gone to London or almost (perhaps it had better have gone nearer or kept further away, for the sake of its exchequer), still it is the pleasantest of all shows. Each year I think so, each year I find it to be so. The first week in June is the very bloom and perfection of all the summer—the early, early summer time, when the season has come in its beauty, and as yet there has been no in-gathering, not even of a blade of grass, no scythe has as yet invaded the grassy sea, which this lovely breezy 1st of June is seen by me gently moving in the sunlight. The waves of shadow are going over the grassy slopes; all is early summer—not a tinge of autumn, nothing finished, nothing done with; all so new, and green, and clean. Such were some of my thoughts as I walked from Waddon station to the Show yard, and albeit though my old friend B. & W. has gone to London this year for the season (oh! gay B. & W.!), yet it has pitched its tents in a most perfect bit of country. That winding lane from Waddon station is a perfect country lane, and the views around genuine Surrey views—that is, open, and clear, and pleasant, with a healthy, sweet-tasting air coming to one's lips, for I hold we can taste the air. All at Waddon village is "truly rural;" though from what I see those testing words of the policeman to the drunkard would be pronounced by many not "truly rural" but "tural lural." Oh! why will men drink without eating, and in hot weather too?

Well, I am at the Show; click go the turnstiles, and I am in. Whiz is going, as usual, the machinery in motion, making one hotter than ever. There is the horse ring; there the arts' department; and then my old friend of many years' standing, the

poultry tent, with its many little flags. I enter, and find plenty of room, for no one is there save two policemen—lucky men, standing in the cool opening at either end. I find only about a hundred pens of Pigeons, and some of them even empty. I do not wonder at the smallness of the Show. The poor Pigeons at this season have a please-let me-go-home-to-our-lofts look. They are thinking of those eggs they feel they ought to be on, or those young birds now under the care of somebody else. Winter time is the show time for Pigeons; they are then like young folks "just come out" looking out for mates—not married yet; but now in June domestic life has come with its cares, and Mrs. Ponter and Mrs. Jacobin do not look as sprightly as they did last January 6th. They are no longer Miss Ponter and Miss Jacobin, and look, as we say in Wiltshire, "very much married indeed." But a truce to all reflections. Let me begin at the beginning, and go through the Pigeon pens.

First I must observe of these Pigeon pens that they are a great deal too highly placed. Being put on the top of lofty fowl pens it is not possible to see the birds without tipping on one's toes and straining one's neck; and if I had to do it—and I am a five-foot-ten man—how much worse for the short men! and I heard ladies bitterly complaining; for though swans can stretch their necks, human beings cannot, though I saw some swan-like necks doing their best to add an inch to them.

Carrier cocks (any colour)—First (431), a Black. Eye good, beak not down, wattle good, but in carriage scarcely equal to its Dun neighbour (430), highly commended, both owned by Mr. Fulton. By the way, I see my Scotch friend "Bob" has again changed his residence, and now dates from "*Doo* Lodge, Brockley." Let all readers, specially Americans, understand that does not mean that he will "*do*" any of his customers, for an honester man I know not. This in passing. Second-prize an uncommon nice Dun cock (436), and from Bath, too, I see. He is a bird fully deserving his place. (435), highly commended, a beautiful-plumaged bird. (430), Shoulders well out, statue-like look. I went back twice to look at him. Carrier hens (any colour).—First (440), a capital rich Duo of Mr. Maynard's, a long way the best. Second (439), small rather, but trim and pretty. (444), commended, a promising young hen.

Pouter cocks (any colour)—Here Mr. Fulton had no competitors; two prizes, two birds. First a good Yellow, second a Blue, and fine. As with Pouter cocks so with the hens, two prizes, two birds. First, Blue, rather heavily flagged; second a White, utterly out of show. Both Mr. Fulton's.

Runts—These were for Runts quite numerous, for I remember when only two pens were shown at Birmingham, and here were five. First (453), a wonderfully fine pen of Silvers. The rest good, every one.

Dragoons (any colour).—First (460), a nicely-matching pair of Blues, and not too heavy. Second (463), Duns; these were simply young Carriers, and will be shown as such presently. They were unmistakeably Carriers, with not a Dragoon look about them; hen a very nice young Carrier indeed. The Dragoons mustered ten pens. "How those birds have come up!" said an old fancier to me; "in my young days nobody thought anything of them."

Fantails.—First and second Whites, Mr. Maynard. 469, highly commended, a nice but not well-matched pair of Yellows. If the fair owner can but procure a better mate for her pretty little hen she will rise beyond highly commended or even very highly commended, but the cock bird is coarse, and has too very white feathers in his tail. I venture to hope that Miss Dickinson will persevere with this very pretty colour of a very pretty variety. *Trumpeters.*—First, grand Blacks. Second, good Mottles. 476, highly commended. The right type of bird, Mr. Vander Meersch, but too light in colour.

Barbs—A capital class—one of the very best in the Show. Out of the eight pens five were noticed. Blacks won, but almost every pen was deserving. Mr. Maynard was very fortunate with his birds, beating even Mr. Fulton.

Archangels.—Seven pens of very equal goodness, the colours very glowing, and the birds well shown, some very tame. I often think if other fanciers took pains and made their pets as tame as Ponter fanciers do theirs, they would often gain a point. Here was an Archangel who played up to me, and showed himself off to every advantage. *Turbits*, save the prize birds not good, many dark feathers where only white ought to be. First (493), black shouldered and good.

Tumblers.—Only three pens, two of head-and-beak *Almonds*, and one of *Agates, Mottles. Nuns.*—Mr. Vander Meersch first with a very nice pair of Blacks; indeed, Blacks as usual won. I turn the corner, and my neck is almost broken now. Oh, those shameful and painfully elevated pens!

Owls.—Three pens of foreign, or as Mr. Huie has it, "the kissable variety." First a truly lovely pen of Whites. Second Whites with black tails, very charming birds. Commended 505, a pretty pair of Blues. Well, friend Huie, they are kissable birds, these foreign Owls; but I could, and do, kiss a Jacobin's dainty white head and short face as lovingly.

And here come the *Jacobins*, another popular variety, as the nine pens here proved. First the only real short-faced birds there; they were good Reds. Second Yellows, a trifle coarse, but hood and chain excellent. There were a pair of Whites unnoticed; why I cannot imagine. Probably the Judge was a taller man than I am and could see them better. The Jacobins as a whole were too large; the size wants reducing, and the beaks shortening, and the heads rounding.

Last of all come Any other distinct variety, eleven pens, and four of them empty. First, Mealy Frillbacks; second, Dark-grizzled Frillbacks—rather odd that this singular variety should be so strongly represented—a highly commended pair of Black Mags, and some pigmy Pouters also highly commended.

Such was the Bath and West of England Show as to Pigeons. Pleasant and cool the tent, excellent the supply of water—a great matter in a summer show; but I do trust that the pens will be placed lower another year.—WILTSHIRE RECTOR.

SPANISH.—*Cock.*—Cup, 1, and 2, E. Jones, Clifton, Bristol. *hc*, E. Jones; H. R. Lingham, Acton. *c*, Miss E. Browne, Chard. *Hens.*—1, Miss E. Browne. 2, E. Jones. *hc*, G. K. Chilcott, Montpellier, Bristol; W. Woodhouse, King's Lynn; P. F. Le Sueur, Grand Vale, Jersey. *c*, Mrs E. Allsopp.

DORKINGS (Coloured).—*Cock.*—Cup and 1, F. Parlett, Galleywood, Chelmsford. 2, T. C. Burnell, Micheldever. *hc*, E. Rice, Sandwich. *c*, P. Crowley, Croydon; C. Cork, New Shoreham. *Hens.*—1, F. Parlett. 2, T. C. Burnell. *hc*, A. Darby, Little Ness, Shrewsbury; J. O. Hodges, Bagshot.

DORKINGS (Silver-Grey)—*Cock.*—1, O. E. Cresswell, Early Wood, Bagshot. 2, F. Cheesman, Ashford. *Hens*—1 and 2, O. E. Cresswell. *c*, T. C. Burnell.

DORKINGS (White or Blue).—*Cock*—1, L. G. W. Stratford, West Malling. 2, J. H. Putney, Dorking. *hc*, O. E. Cresswell; J. Isard, Wokingham. *Hens.*—1, O. E. Cresswell. 2, W. Virgo, Guildford. *hc*, A. Darby, Little Ness, Shrewsbury; A. Darby. *c*, H. H. Young, Shapleton, Dorking; J. H. Putney.

COCHINS (Cinnamon and Buff).—*Cock.*—1, F. Hawkins, New Charlton, Woolwich. 2, Mrs. A. Christy, Edenbridge. *hc*, Mrs. E. Allsopp, Worcester; H. Tomlinson; Capt. T. S. Robin. *Hens.*—1, Capt. T. S. Robin. 2, S. R. Harris.

COCHINS (Brown and Partridge-feathered).—*Cock.*—1, T. W. Anns, Clapham. 2, Mrs. E. Pryor, Welwyn.

COCHINS (White).—*Cock*—1, R. A. Bolsier, Penshurst. 2, T. H. Waterman, Anderton, Devonport. *Hens*—1, A. Darby. 2, J. K. Fowler.

BRAHMAS (Dark)—*Cock*—1, Horace Lingwood, Creeting, Needham Market. *hc*, L. Wright; F. F. Ansdell. *Hens.*—1, F. Lake, Rodmersham, Sittingbourne. 2, T. F. Ansdell, Cowley Mount, St. Helen's. *c*, L. Wright; Rev. J. D. Peake.

BRAHMAS (Light)—*Cock.*—1, Horace Lingwood, Creeting, Needham Market. 2, P. Haines, Palgrave, Diss. *hc*, Capt. W. Savile. *Hen.*—1, Mrs. Peet. 2, Capt. W. Savile. *hc*, E. Haywood, Uckfield; J. Bradshaw, Knowle, Cranleigh.

GAME (Black-breasted Reds).—*Cock.*—1, J. Mason. 2, W. J. Pope, Biggleswade. *hc*, S. Matthew, Stowmarket; E. C. Pope, Falmouth; W. H. Stagg. *c*, T. C. Ledger. *Hen.*—1, S. Matthew. 2, W. J. Pope.

GAME (Brown breasted Reds)—*Cock.*—1, J. Icken. 2, S. Matthew. *hc*, H. E. Martin. *Hen.*—1, S. Matthew. 2, H. E. Martin. *hc*, W. Foster; H. Browne.

GAME (Duckwing and other Greys, Blues, Blacks, and Whites).—*Cock.*—1, W. C. Phillips. 2, D. W. J. Thomas *hc*, G. H. Fitzherbert, Sevenoaks; E. G. Farquharson. *c*, W. L. Blake. *Hen*—Cup D. W. J. Thomas. 2, S. Matthew.

HAMBURGHS (Golden-spangled).—*Cock.*—1, T. Dean, Keighley. 2, H. Belden, Goitstock. *c*, J. Long,. *Hens*—1, W. Driver. 2, T. Dean. *c*, H. Beldon.

HAMBURGHS (Silver-spangled).—*Cock.*—1, S. R. Harris, Cusgarne. 2, F. Hawkins. *hc*, H. Beldon; J. Long. *Hens.*—1, Miss E. Browne. 2, H. Beldon.

HAMBURGHS (Golden-pencilled).—*Cock*—1, W. Driver. 2, H. Beldon. *hc*, J. Long. *Hens.*—1, C. Judson, Rye Lane, Peckham. 2, J. Long. *hc*, T. Reeves.

HAMBURGHS (Silver-pencilled).—*Cock.*—1, H. Beldon. 2, F. Hawkins. *Hens.*—1, H. Beldon. 2, B. Norton, Town Malling.

POLISH.—*Cock.*—1, H. Beldon. 2, T. P. Edwards, Lyndhurst. *hc*, D. Mutton, Brighton. *c*, C. Bloodworth, Cheltenham; G. J. Lenny, Lewes. *Hens.*—1, H. Beldon. 2, T. P. Edwards. *hc*, D. Mutton; C. Bloodworth; C. W. Shepherd.

HOUDANS.—*Cock*—1, W. Dring, Faversham. 2, F. Brewer, Lostwithiel, Cornwall. *Hens*—1, S. W. Thomas, Sketty, Swansea. 2, G. D. Harrison, Datchet. *hc*, Mrs. Schroder. *c*, W. Dring.

CRÈVE-CŒURS.—*Cock*—1, F. Lake. 2, Mrs. A. Christy, Falkoners, Edenbridge. *hc*, J. K. Fowler, Aylesbury; J. J. Malden. *c*, W. Dring; J. J. Malden. *Hens.*—1, J. K. Fowler. 2, J. J. Malden. *c*, F. Lake, Rodmersham, Sittingbourne.

ANY OTHER DISTINCT VARIETY—1, G. De Faye, St. Helier's, Jersey. 2, S. R. Harris. *hc*, H. Beldon; G. R. Smith, Croydon; R. R. Fowler. *c*, J. Croote, jun.; *Hens.*—1, Miss S. H. Northcote. 2, T. G. Ledger, Folkestone. *c*, R. R. Fowler.

DUCKS (White Aylesbury).—1 and *hc*, J. K. Fowler. 2, S. R. Harris.

DUCKS (Rouen).—1 and 2, W. Evans. *hc*, F. Parlett.

DUCKS (Any other variety)—1, R. Wilkinson. 2, G. S. Sainsbury.

TURKEYS—*Cock*—1, F. Warde. 2, H. J. Gunnell. *c*, N. J. Ridley. *Hen.*—1, N. J. Ridley. 2, F. Warde.

GEESE.—1, J. K. Fowler. 2, G. H. Fitzherbert.

BANTAMS (Gold and Silver Sebrights).—1 and 2, Rev. G. F. Hodson.

BANTAMS (Black or White)—1, O. E. Cresswell. 2, E. Cambridge. *hc*, H. Beldon; C. W. Gedney.

BANTAMS (Game).—1, J. Andrews. 2, T. Randall, jun. *hc*, G. Hall.

BANTAMS.—*Cock.*—1, G. Hall. 2, R. Brownlie. *hc*, T. W. Anns; M. V. Sandford.

PIGEONS.

CARRIERS.—*Cock.*—1, R. Fulton, Brockley. 2, J. James, Bath. *hc*, R. Fulton; H. Yardley. *Hens*—1, H. M. Maynard. 2, R. Fulton. *c*, J. James.

POUTERS.—*Cock.*—1 and 2, R. Fulton, Brockley. *Hen*—1 and 2, R. Fulton.

RUNTS.—1, H. Yardley, Birmingham. 2 and *c*, J. S. Price, Finchley.

DRAGOONS.—1, H. Yardley. 2, J. James. *hc*, R. Fulton; W. D. Richardson.

FANTAILS.—1 and 2, H. M. Maynard. *hc*, Miss Dickinson, London.

TRUMPETERS.—1 and 2, R. Fulton *hc* and *c*, A. A. Vander Meersch.

BARBS—1 and 2, H. M. Maynard. *hc*, R. Fulton. *c*, Rev. A. G. Brooke.

ARCHANGELS.—1, E. S. Carew-Gibson, Springfield, Shirley. 2, J. Bowes, Herne Bay. *hc*, O. E. Cresswell. *c*, H. W. Webb.

TURBITS.—1 and *hc*, O. E. Cresswell, Early Wood, Bagshot. 2, R. Fulton.

TUMBLERS.—1 and 2, R. Fulton. *c*, H. Yardley.

NUNS—1, A. A. Vander Meersch, Tooting. 2, T. Homes, Lower Sydenham.

OWLS.—1, R. Fulton. 2, H. W. Webb. *c*, Rev. A. G. Brooke, Shrewsbury.

JACOBINS.—1, O. E. Cresswell. 2, R. Fulton. *c*,—Vander Meersch.

ANY OTHER VARIETY—1, R. Fulton. 2, H. W. Webb, Lower Sydenham. *hc*—Vander Meersch; T. Homes. *c*,—Vander Meersch; J. James.

RUGBY SHOW OF PIGEONS, &c.

THE second annual Show was held at Rugby on Tuesday and Wednesday the 25th and 26th ult., in the Working Man's Club Rooms. The amount of prizes offered was very small, but some extras were offered by tradesmen of the town, and these proved attractive, and though the classes were not numerous the entries were good. Some of the extra prizes were, however, offered in a most curious manner, as for example, a champion prize was competed for by Cage Birds and Pigeons, and this we may here state was won by Mr. Yardley's Almond. Another champion

prize was for Rabbits and Cats, this being won by Mr. Hudson with a yellow-and-white Lop doe.

Pigeons were the first section, Pouters, Tumblers, and Foreign Owls competing together, an Almond being first, an Agate second, and Pouter third. Carriers or Barbs came next, a Black Barb cock standing first an easy winner; a Dun Carrier hen, stylish but short of beak wattle second; and a Dun cock good in beak but short of eye third; a good Black Carrier hen though young being very highly commended. English Owls or Turbits were the next class, a grand Silver Turbit being put first, the second a Silver Owl good all round, and third a Blue Owl cock, very good in head properties but not in the highest order. Dragoons came next, a model Yellow winning first and the two plates of Rugby School, second coming a good Blue, and third a Blue hen of good quality but young, and being a hen not showing well against the cock, while many birds were too long and fleshy in eye. The Homing Antwerps were a grand class, and though the doings of the winners are unknown to us, such were the points and qualities of the winners that under favourable training we are thoroughly satisfied that their doings would be something grand; and we would here remark that to be clean and well marked is no disadvantage in a flying bird, the points which we took as guarantees of worth being the style and carriage of a Carrier combined with a quick eye, intelligent head, short broad flights and tail, and well-developed chest and arm, and if these points can be combined with correctness of colour and marking we say it is a great advantage in either cote or show pen. Many other good birds were noticed. Fantails were a good lot, and an extra third was awarded, the winners being White. In the Variety class a Black Fairy Swallow was first, and Blue Brunswick second, and a Dun Shortface Antwerp third. Mr. Yardley won the point cup for Pigeons.

Rabbits were a capital entry in all classes, the Dutch, for which this locality stands well, outstripping all other classes we have seen of this variety. In Lop-eared, four pens were empty —viz., those of Messrs. Barker, Fell, and Lamb. First was a yellow-and-white doe looking a little worse for wear, but still grand, 23 by 4¾ inches. Second an immense Tortoiseshell doe, good in colour, dewlap, &c., 21 by 4½ inches; the third a fawn-and-white buck, 21½ by 4¾ inches. A grey-and-white doe very good, but low in condition, 21½ by 4½ inches was very highly commended. In Silver-Greys we were told the three winners were all from the same stock. The cup for all, Lop and Dutch excepted, being awarded to Mr. Hudson's buck. In Dutch the above-named gentleman carried off both first and second, a great feat in our opinion. The first was black, and second grey. The third was also black, and there being a great number of very young Rabbits of a promising character, several extra thirds were awarded, as also many other notices. The prevailing fault in this class was a slight unevenness of nose. One of the very best in the show was spoiled by size alone, and was very highly commended. The first in Himalayan was a grand Rabbit. Second good in all but feet. Third very young, had not good ear colour, or it would most decidedly have been higher. In the Variety class a Belgian Hare of rare colour was first; an Angora second, and a Belgian Hare third. The latter was very good in fur, but out of order. In the Selling class a young Fawn Lop, 20½ by 4¾ inches, was first; a Blue Dutch almost equal to the winner in the ordinary class second, and a Belgian Hare third.

There were but four classes for *Cage Birds*, all the Canaries being thrown into one. First was a Variegated Norwich of rare colour of the high-fed class; second a Lizard (Golden), the best backed bird we have seen this year, the only fault, and that but slight, was a little irregularity of marking over the left eye. Extra second was a Clear Jonque Norwich, almost equal to the first for colour, and by the same exhibitor. Third a grand Cinnamon. Extra third a Variegated Mealy Norwich, many other excellent specimens being noticed. For Mules only one prize was offered, and there were four entries, this award going to a Variegated Linnet Mule, which award did not seem to please our Coventry friends, but our experience is between equal birds in Goldfinch and Linnet Mules that the Linnet is most difficult to breed. In the British Birds a Magpie was placed first, she was a grand specimen, the Goldfinches and Linnets proving but poor. In Foreign birds a Grey Parrot was first, and a Green one second. The third also was a Green, and this bird told us that "Polly gets the prizes," but that must be when Polly is a little cleaner and tighter in feather.

Of *Cats* there were two classes, the Long-haired being poor, while in the next class was a Tortoiseshell-and-white, and consequently unnoticed, that might have won easily in the former. The well-known Cat "Lion" took the cup, some other good Cats competing here, the second being White, and third Grey Tabby. An extra prize was awarded to Mr. Geans for his Belgian Hare, but this was not in the schedule.

Turner's pens were used, and the Show well managed in all respects. The rooms though small were light and airy.

PIGEONS.

Pouter, Almond Tumbler, or Foreign Owl.—*Cock or Hen.*—1, Extra, 2, H. Yardley, Birmingham. 3, C. F. Herrieff, Banbury.

Carrier or Barb.—*Cock or Hen.*—1, Extra, 2, and 3, H. Yardley.

English Owl or Turbit.—*Cock or Hen.*—1, H. Yardley. 2, J. Shillingford. 3, J. Barnes.

Dragoon.—*Cock or Hen.*—1, Extra, and 2, R. Woods, Mansfield. 3, H. Yardley.

Homing Antwerp, or Likeliest Bird for Flying Purposes.—*Cock or Hen.*—1, C. F. Herrieff. 2 and 3, W. Bates, Rugby.

Fantail or Jacobin.—*Cock or Hen.*—1 and 3, J. F. Loversidge, Newark. 2, H. Yardley.

Any other Variety.—*Cock or Hen.*—1, H. Yardley. 2, J. Shillingford (Priest). 3, L. Carleton, Rugby (short-faced Silver Dun Antwerp).

CAGE BIRDS.

Canary.—1, R. J. Pope. 2, 3, and Extra 3, J. Adams, Coventry. Extra 2, R. J. Pope, Brighton.

Mule.—1 and Extra, J. Bexson.

British Bird.—2, C. Foxon, Lutterworth. 2, G. E. Russell. 3, Miss Allen, Rugby.

Foreign Bird.—1, Mrs. Salmon. 2, H. Jelly. 3, C. Gascoigne, Rugby.

RABBITS.

Lop-eared.—*Buck or Doe.*—1 and Extra, A. Hudson, Hull. 2 and 3, Mrs. H. Pickworth, Moulton Marsh, Spalding.

Silver-Grey.—*Buck or Doe.*—1, Cup, and 2, A. Hudson. 3, B. Greaves, Cleethorpes.

Dutch.—*Buck or Doe.*—1, Extra, and 2, A. Hudson. 3, B. Greaves. Extra 3, Master E. Campbell; B. Greaves (2).

Himalayan.—*Buck or Doe.*—1, Mrs. H. E. Gilbert. 2, H. T. Hincks. 3, B. Robinson.

Any other Variety.—*Buck or Doe.*—1, B. Greaves (Belgian Hare). 2, H. T. Hincks. 3, G. H. Robinson (Belgian Hare).

Selling Class.—1, A. Hudson (Angora). 2, H. E. Gilbert (Dutch). 3, G. H. Robinson (Belgian Hare).

CATS.

Long-haired.—*Male or Female.*—1, R. Over, jun., Rugby. 2, Mrs. D. Hanbury, Chilton, Rugby. 3, A. Diver, Rugby.

Short-haired.—*Male or Female.*—1 and Cup, E. Baxter, London. 2, Mrs. Salmon. 3, C. F. Smith, London. Extra 3, H. B. Hensman, Rugby.

WINNERS OF POINT AND CHAMPION PRIZES.

Greatest number of Points in Pigeon Classes, H. Yardley.
Greatest number of Points in Rabbit Classes, A. Hudson.
Best Pen in Pigeon and Cage Bird Classes, H. Yardley.
Best Pen in Rabbit and Cat Classes, A. Hudson.

Judge.—Mr. E. Hutton, Columbarian House, Pudsey, Leeds.

NESTS FOR PIGEONS.

A useful form of nest for Pigeons, which I have not seen in use, is a modification of an ordinary shop till, and is, I think, an improvement on the usual earthenware pan. It is simply a rough block of wood of the required size, with a hollow for the nest; a useful size is 1 foot square by 4 inches deep, the hollow 9 inches across and 3 inches deep. Any carpenter possessing a lathe could produce them for a few pence. Their advantages are that they stand perfectly steady, afford a good ledge for the birds when entering or leaving the nest, and are not so likely to crack the eggs as earthenware. They are better than baskets, because they do not harbour vermin and can easily be scraped and limewashed after each sitting. I like them of such a size as just to fit behind the usual blinds, which I prefer to hang on hinges in the form of a door, as I can then get at the interior better with the lime brush.

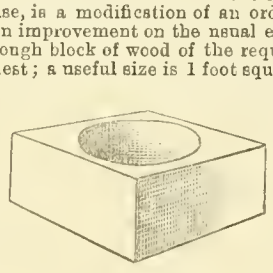

Fig. 103.

I suppose nine out of ten beginners are advised to use the earthenware basin, and place a brick in front to assist the birds into bed and prevent an upset, but this at best is a slip-shod contrivance.

The woodcut will perhaps give a better idea than words of the form I recommend.—Sciolist.

[The above plan for a Pigeon nest strikes me as good. I would merely add that it should be formed of wood that would not warp, and also that it be thoroughly well painted, not one coat merely, with oil paint. Then a cleansing would be easier and more effectually made by washing, and it would be a neater plan than limewash. The depth need not be so great as 3 inches, for I fully believe Pigeons prefer a shallow nest. The pans I use in my loft are 3 inches in depth, but I do not mean to have any more quite so deep. A scraper in the shape of a half moon (some meat-choppers are made in this form) makes the best instrument for cleaning the nest out thoroughly. I saw one in use in Mr. Heath's (of Calne) loft recently, and thought the idea a good one.—Wiltshire Rector.]

YORKSHIRE CANARIES.

At one period (none other than the last Canary-exhibiting season) I began to imagine that Yorkshire birds were becoming as numerous as were the acres of land in the county of (as the vernacular tongue of the locality expresses it) "Yark." I will not be too precise, however, upon that point, as I am "at sea" just now as to the exact number of acres of land the county possesses. However numerous may be Canaries bred in the county, still the vast number is further enhanced by those bred annually in the adjacent districts.

In the north of England the breeders of Yorkshire Canaries

vie with their southern or midland brethren, who devote their time more to the breeding of Norwich birds, once designated in a letter to me from Kilmarnock as "painted spuds," or in other words coloured sparrows.

Some idea of the number of Yorkshire birds bred may be formed from the fact that no less a number than eighty-nine picked specimens, sent by various noted breeders, put in an appearance at one of the north of England exhibitions last season. The schedules issued from South Stockton, Guisborough, Middlesborough, Darlington, York, South Shields, Bedale, Penrith, and Baildon, and likewise Northampton and Norwich, were responded to spiritedly, and many fine birds graced the show stages.

Unlike the Norwich breeders, who pride themselves more particularly respecting form and colour, several breeders of so-called Yorkshire birds have introduced as a cross the Coppy strain (the plain-headed birds), which has resulted in the production of unwieldy-looking specimens, not at all answering to the true type of Yorkshire birds. Not unfrequently have I had to pass by specimens bulky or "bullocky" in shape, exactly in appearances Manchester Plain-heads, preferring those of a medium size, and somewhat more slim in make and general contour.

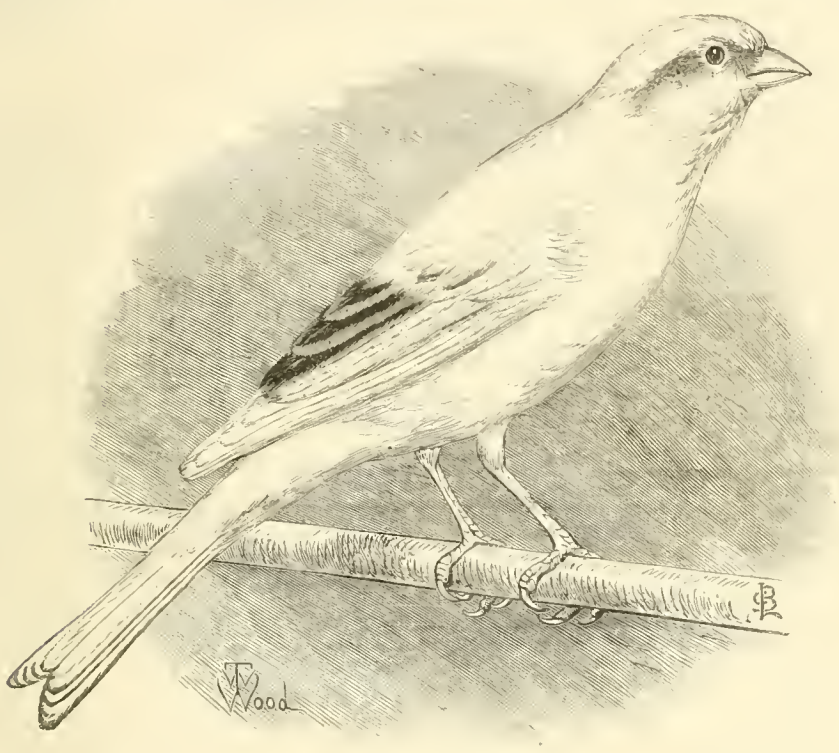

Fig. 104.—Yorkshire canary.

At several shows half a dozen classes are set apart for Yorkshire-bred birds, two of which are appropriated to Clears (Yellow and Buff), two for Even-marked, and two more for those Uneven-marked. Some fanciers prefer a six-marked bird, thus: Spectacle-eye marks, dark and regular, smaller or lesser flights, and the tail with a dark feather in each side. To breed a bird marked to such a degree of nicety is a somewhat difficult matter, and were judges to make choice only of six-marked specimens there would be fewer even-marked birds shown.

The illustration represents a four-marked Yorkshire Canary, possessing nicely-pencilled eye marks and dark lesser flights, but tail entirely clear. It was sketched from a bird (No. 591 exhibited at the last Crystal Palace Bird Show by Mr. Luke Belk of Dewsbury, Yorkshire, a breeder of some repute of this particular kind of Canary, who won the first prize in Class 23, for "Clear, Marked, or Variegated Yorkshire." At the Palace Exhibition there were but a dozen specimens exhibited in the class, some of them of note as prize-winners at previous all-England shows, creditable alike to their owners for the condition they were in when sent for exhibition, especially those shown by Mr. Belk (whose better-half also takes vast interest in the fancy of her husband, and may be seen interesting herself at most of the north of England shows), and Messrs. Tomlin, Wilkinson, and Mackley. Evenness of marks to a great degree assisted Mr. Belk's bird in defeating Mr. Tomlin's fine clear specimen, which, if I am not mistaken, has succeeded more than once or twice as a first-prizetaker.

In the past season generally the Yorkshire birds were a source of great attraction (sometimes a little sensational), but no show held presented a finer display of real quality birds than the one held at Baildon, for apart from any remark of an hyperbolic character, I never remember witnessing a finer lot of Yorkshires than Mr. Myers Mann and the Baildon executive collected together from the various exhibitors in England. The first-prize bird exhibited by Messrs. Hutton & Thackray was a complete pink of perfection, and well represented the breed of Yorkshire Canaries. The bird was justly awarded a cup.

In colour the Yorkshire Yellow bird is more of a lemon tint, although endeavours have from time to time been made to introduce the colour of the Norwich. This cannot be effected without materially affecting the form of the bird, and somewhat contracting its length, which is as great an evil as the cross with the Manchester Canary. The Buff or Mealy birds are lighter-coloured than Norwich birds, but of a close soft appearance of plumage.

The chief characteristic points of the Yorkshire bird are:—

Beak somewhat slender.

Head round and moderate in size.

Neck straight and longish.

Shoulders rather broad, but not too much so, and not high.

Back well filled in and straight.

Stand, firm and of bold carriage.

Wings long, and not crossed at the tips.

Legs rather long.

Feet and Nails not coarse or twisted awry.

Feathers close and perfect. (This point I look upon as a most important one—viz., closeness and condition of feather and the reverse of being coarse. In breeding or crossing-in with the Manchester blood, closeness of feather becomes deteriorated and loose).

Tail close and straight. (Pipy-inclined, not fish-tailed.)

In the marked specimens the additional points are—

Eyes. — Pencilled from the beak slightly on each side of the eyes regularly, and tapering towards the neck. This is preferable to the pencilling suddenly chopping off immediately behind each eye. The pencilling about each eye should correspond as nearly as possible.

Lesser Flight Feathers.—Dark without any tendency to greyness in the webbing. The more solid the colour the better, and there should be no intermixture of light or white feathers with the dark ones.

Tail either clear or a dark feather on each side. Regularity is an important consideration.

The body and entire bird otherwise should be free from ticked or dark feathers. In an uneven-marked specimen it is of no consequence.—Geo. J. Barnesby.

DETECTING THE SEX OF EGGS.

I have noticed more than once in your paper an observation to the effect that the sex cannot be detected. Perhaps not with certainty; but there is a mode in use in the country which has not, I think, been alluded to by you. It is this: By holding the egg before a strong light and making a telescope of the hand, a dark portion will be visible, and its position is indicative of the sex—*e.g.*, if on the top of the yolk it is a cock certain, if nearly on the top a cock probably; if on the side, midway, a hen certain. I know a man so practised at the examination of eggs for setting as to feel confident in the truth of the theory and of his own capability of discriminating. That is to say he would guarantee from a lot of eggs to choose a setting of hens certain, or otherwise as desired.—H. G. Watson.

[We have kept and studied poultry more than forty years—long enough to teach us we know very little on the subject.

We do not discontinue our observations and experiments, and now and again we learn something. Doctors are often in their opinions wide as the poles asunder, yet like your authority they are both "confident." A short time since two men wrote on consumption. Mr. B said salt was a cure, and often a preventive. Mr. H said the disease would be unknown if no one ate salt. Twenty years ago two professional men came to us, asking permission to pick out of a large number two experimental sets of eggs. We agreed on condition that we should be told the intention and the result. One wished for all cocks, the other pullets. Both hatched a mixture of sexes. The old theory was and is, the cock is hatched from a pointed, the pullet from a round egg. Old cockers in the north and north-western parts of England still profess to choose sittings to produce all cocks. They are never right throughout, and they never publish their failures. Our experience goes to tell us that the first eggs of the season—that is, the first laid eggs of the year, produce more cocks than the subsequently laid eggs; we cannot tell why, nor can we discover any difference between the first eggs and others that come after. At the end of five days or a week we can tell the fertile from the bad eggs by the first development of the germ of life: it is plainly visible. Beyond that our knowledge does not go. We promise we will go into some other experiments, and we will communicate the result. Our present belief is that it is impossible to foretell the sex of the chicken from any examination of the egg. It is a pity it has never been tried under circumstances that might bring about an authoritative settlement of the question. It was tried by the ancients, but although they have left on record the means employed and believed in by those who used them, we have no record of success, nor any rule that can be followed now.

There are always amateurs who wish for young birds to bring up under caged adults that have properties or talents they wish to perpetuate. It is rather a troublesome process, and the young in a nest are painfully alike. To rear a number of hens would be labour lost. Practised and clever men who make such things their study have discovered that at the time when the young are about half fledged, the top bird (and one is always above the others) is always a cock.]

BOILING EGGS.

Mr. Radclyffe, on page 402, gives us the Oxford mode of preventing the white becoming tough. I have long followed another method—namely, putting the egg into cold water and allowing it just to come to a boil. Brande puts the coagulating point of white of egg as low as 150°, and it is certain that 212° is quite unnecessary. Neither Mr. Radclyffe's plan, however, nor mine will succeed unless there is a sufficient quantity of water. The minimum quantity might be found out by experiment. In my plan also care must be taken that the fire is not too fierce, or the water will boil before the egg is cooked.—G. S.

WEAK STOCKS.

I have two boxes of bees standing by the side of each other, one weighing 20 lbs. without box and floor-board, but having very few bees in it; and I do not see them work or take anything into the hive. I can see in at the window that there is plenty of honey. Shall I put a swarm into it if I have one, or what would you advise me to do?

The other hive has a very small number of bees, and they have no new comb, but only a few pieces made last year. I have another hive which did nothing last year, it neither swarmed nor worked in the super, and they do not appear very promising this year. I have some stocks doing very well. There have been several swarms near me, but I have not had one yet.—F. G.

[Your three stocks are in a bad way. We should advise you to examine the two first hives with "plenty of honey." Cut out any mouldy or defective combs you may see, and put the first swarms into them; they will start well, and probably give you a lot of honey later on. Do the same with the hive containing only a few pieces of comb. You need not trouble about the few bees that remain, as they will probably join the swarm without the loss of a single life. Should there be any queen, it will either be conquered if weak, or conquer and reign if strong.]

OUR LETTER BOX.

Wishaw Poultry Society.—Is it customary with this Society not to pay prize money to competitors after they have gained the prize? I competed at the last Show, gained two prizes, have written three times for the prize money and have not got it.—James Kirkland, *Stewarton*.

Bullfinches Taken in the Nest (*M. J. C.*).—The best food on which to rear young Bullfinches when taken in the nest is rape seed mixed with stale roll or buckwheat, grits, and a little plain biscuit, each steeped in milk. The young should be removed when about twelve to fourteen days old, when the tail feathers begin to push. Feed the birds early in the morning and frequently during the day. If it is intended to learn the birds to pipe a tune, keep them entirely out of the sound of all other birds, as they quickly acquire any harsh notes, and which they will rarely ever quit. The male birds can be known in the nest by the tinge of red on the breasts, if you wish to select them. The hen birds will also learn to pipe, but not so well as the males. When young Bullfinches begin to feed themselves they will get into voice and pipe in their natural way. Young birds should be treated tenderly, and they soon learn to know those who attend upon them.

Stock of Driven Bees—Bees Clustered Outside (*G. L.*).—We think that your hive which was peopled in August last year, and which has drones in it now, is thriving and healthy. Probably the bees built some drone combs near the centre of the hive, which are now yielding drones before the hive is full. If it does not fill and work better soon, you may suspect that something is wrong. An examination of it internally will enable you to discover whether it has lost its queen or is otherwise affected. Your other two hives are ready for swarming, and will probably swarm on the return of warm weather. In nineteen cases and nineteen seasons out of twenty such hives swarm. Clustering at the doors of hives (rather small) is generally a preliminary to swarming, and not an indication that the bees will not swarm. If you have not time or patience to watch and wait for the bees swarming of their own accord, you could resort to the artificial swarming, which is so easy of accomplishment.

Cheapest and Best Hive (*J. Berry*).—No one can answer your question without knowing whether you wish for honey or swarms, whether to see the bees working, or whether you wish to prevent swarming. The cheapest hive on the depriving system is Payne's straw hive and straw super.

REMARKS.

26th.—Rather dull till 4 P.M., after that time fine and pleasant.

27th.—Fine early, but soon becoming dull, though still fair, and so continued all day.

28th.—Cloudy early, rain at 9 A.M., dull morning; fine for a short time in the middle of the day; heavy rain at 9 30 P.M., and slighter rain after.

29th.—Rain in the past night, early morning, and slight occasionally during the day, which was dark, cold, and disagreeable.

30th.—A very pleasant day, bright and sunny but not hot.

31st.—A very fine day throughout, but rather cool for the season, the wind being easterly.

June 1st.—A complete summer day, bright, sunny, and warm.

Colder by 2° than the preceding week except under ground, which has only decreased 0.2°. The weather generally pleasant, but rather cold for the time of year.—G. J. Symons.

COVENT GARDEN MARKET.— June 2.

The markets have been well supplied during the week, and a free supply may be looked for now both in fruit and vegetables, the Continent and Channel Islands sending heavy consignments, especially of Early Ashleaf, which are now selling at 14s. to 21s. per cwt. The last cargo of St. Michael Pines by one of the Mail steamers has been disposed of at fair rates for the season.

From observations taken near London during forty-three years, the average day temperature of the week is 71.8°; and its night temperature 47.6°.

FINE-FOLIAGED PLANTS FOR INDOOR DECORATION.

IN a former paper, while advocating principally flowering plants for house decoration in autumn and winter, I stated that there is something refreshing in the appearance of fine foliage in the heat of summer, I may add that there are niches and corners in mansions where symmetry rather than colour is wanted; where a noble Palm or a graceful Fern judiciously placed seems to harmonise so thoroughly with the architectural and other permanent ornaments, that to remove the plant seems to leave an almost irremediable blank. For such places the two classes of plants named (Palms and Ferns) undoubtedly contain many species and varieties, which can have no competition from any other class; but unfortunately many of the plants are costly, and proprietors who pay away considerable sums in the course of the season to have their town residences furnished in perhaps a third-rate manner, will not employ a competent person to look after the plants, but expect their domestic servants to do it; or, what is as bad, they employ someone in a small way of business who has neither the taste nor the ability to decorate well, but who understands one thing perfectly—making out his account. It would be far cheaper in the end to employ a competent person, to say nothing of the pleasure and good temper derived from seeing the work well done. We know by experience what our great furnishing houses can do when appealed to on special occasions, and even what can be effected by a competent private gardener who has the material to select from. I see no reason why the London mansions of the wealthy should not be perpetual conservatories during the summer season, and I believe many of them might be so for the same or little more than the sum now expended merely for floral decorations on special occasions. I do not, however, expect proprietors to take my view of the matter directly, and meantime I will name a few effective plants which are very easy to grow, and which when grown and placed in position if either the housemaid should drown them, or the footman allow them to be dried up, the pecuniary loss would not be very great.

The first on my list is the Palma-Christi, or Castor-oil Plant (Ricinus), of which there are several distinct and striking varieties, some with glaucous light-green foliage and stems, as in R. africanus, and others with red stems and bronzy leaves a yard wide, as in R. Obermannii, and all of them, if grown quickly without being stunted, almost rivalling the Palms. The seeds of these, which can be bought for a few pence, should be sown in brisk heat six or seven weeks before the plants are required, and hardened in an intermediate house. They can be used in the mansion with grand effect long before anything of the sort can breathe the outdoor air with safety. If not required till the spring is somewhat advanced they may be raised in a frame, or even in a warm room, but they must never receive a check. Seeds of this kind of plants are generally sown too early; ours for the flower garden in summer, where they attain a height of 10 or 12 feet, are never sown till May, and are planted out after the middle of June.

Melianthus major is another grand Palm-like plant for either indoors or out. It is of slower growth than the Ricinus, and should be sown early in January in heat and afterwards hardened, when it will bear without injury several degrees of frost. Acacia lophantha, sown at the same time, makes plants 18 inches high in three months, which are admirably suited for grouping. If larger specimen plants are required seed should be sown the previous summer, and the plants merely kept from frost. There are many other good plants which may be easily raised from seed and used for the above purpose, as may be seen by referring to a catalogue of subtropical and ornamental-foliaged plants, but I think I have named the very best.

Then, again, among the greenhouse Conifers there are several shrubs admirably suited for this purpose—notably Araucaria excelsa. Amongst other greenhouse plants are Dracænas, Cordylines, Ficus elastica, Abutilons, Aralias, and Musas; and amongst hardy plants perhaps the best are Yuccas and hardy Ferns. The latter might be potted the previous season, and forwarded in a greenhouse.

I do not think it well to use very many variegated and coloured leaves in decorating a mansion, and those which are used should be distinct and decided. There is generally not sufficient light to bring out colours which are not bright in themselves, and often the prettiest colouring is on leaves which are otherwise heavy in appearance, as, for example, the fine-leaved Begonias. It is safer, therefore, when experimenting, to trust rather to beauty of form than to beauty of colour; and after the miles of bricks and mortar, dust and hot pavements one has to pass in London, I think it would take a large quantity of well-placed Palm and Fern-like foliage to tire the eye, especially now that there are such masses of cut flowers used.

Plants of thick close growth should never be used, but only those which are light and airy, although they may be large and grand, as in the Palms, and of course they should not be crowded. I consider that, although foliage plants are easier to grow than flowering plants, it takes greater taste to place them in position; for they at once detract from or they greatly add to the general embellishments. The illustration and note about the pots on page 415 is very opportune, and should be constantly borne in mind.

It is a good plan to plant Lycopodiums to cover the soil in the pots. I also have a quantity grown in small pots for placing amongst the plants when they are used in groups. Kept growing, it has a much better effect than dying moss or branches would have. Some of the climbing Club Mosses, Ivies, and other plants might be grown in the same way for drooping round the edges of baskets and vases. For this purpose the green Loosestrife (Lysimachia nummularia) is very suitable, for it

will flourish in any temperature, and even with a deficiency of light falls more closely over the sides of the pots or baskets than it does when grown in a more natural manner with abundance of light and air.—William Taylor.

THE CINERARIA.

This is one of our most useful cool greenhouse plants for midwinter and spring decoration, for which it has few equals; it is also valuable for cut flowers. It is so easy to cultivate that almost anyone may grow it. Usually the plants are grown from seed, but they may be increased by offsets. Those who have old plants of any good variety, and wish to increase them, can do so as follows.

As soon as the plants are out of flower cut them down to within 2 inches of the surface of the soil to induce them to make fresh growth from the bottom. At this stage the supply of water must be reduced until they show signs of growth. But the simplest plan is to plant them out in a shady border, giving them a little water when required. By July or August there ought to be some signs of growth, and the offsets, when sufficiently long and have emitted rootlets, should be taken off and potted in rather small pots. Place them in a cool pit or frame, or hand-lights would do, keeping them rather close for a few days until they are established, but shaded from bright sun. When sufficiently established they will do in any cool shady place, such as behind a north wall or hedge, but not under trees. By the time the pots are filled with roots fine foliage will begin to develope itself. At this stage they must be repotted into larger-sized pots, taking care to have the balls thoroughly moist before repotting. Avoid large shifts, but they must be sufficiently large so as to keep the plants growing, as any check to free root-action is very pernicious. A 6-inch pot will grow a very useful-sized plant suitable for most ordinary requirements, while large plants for exhibition purposes are grown in 9-inch pots.

The soil to grow them in should consist of good turfy loam and leaf mould or well-rotted manure; if the loam is of a retentive nature add a sprinkling of sharp sand; a little charcoal dust is also a good addition. These ingredients well blended together will, with ordinary care, grow good plants.

Drainage is an important point—indeed, the future well-being of a plant will often depend much on the proper drainage of the pots. These must be thoroughly clean, and if they happen to be new and fresh from the pottery they ought to be thoroughly soaked in a tub of water previously to being used. These little matters if neglected will often cause some anxiety to plant-growers, as the dry pots will absorb the water which ought to nourish the plants. A good-sized piece of broken pot should form the foundation of the drainage, or an oyster shell will do as well, then a few more broken pieces on the top of the large piece. A light sprinkling of dry soot at the bottom of the pots will keep worms at bay. This may be mixed with the rough material which is placed over the crocks to keep the soil from the drainage.

The pots should never be filled too full of soil, but space should be left to hold sufficient water to percolate the entire mass of soil and roots. After each potting water must be rather sparingly used until the plants establish themselves in the new soil.

A cold pit or frame with a north aspect, but which can have an hour or two's sun night and morning, is suitable for growing the plants, but in all cases avoid a powerful midday sun. The pit sashes should be left off in fine weather, but they ought to be in readiness in case of heavy thunderstorms or hail, which would at once spoil the beauty of the plants. Night dews are very refreshing. By the time the pots are filled with roots good foliage ought to be hanging over the sides of the pots. At this stage the plants should never be allowed to flag for want of water, or they will certainly be attacked by green fly. I have always found it beneficial to water the plants overhead once or twice a-day in hot weather, with a fine-rose pot. Whenever the blooming-pots are full of roots a little guano water, an ordinary handful to every four gallons of water, applied to the soil two or three times a-week will be beneficial.

The plants cannot be grown too cool so long as they are kept from frost. In the winter they are best kept in cold pits with just sufficient means to keep off frost, or in a cool house near to the glass, giving air on all favourable occasions. Avoid as much as possible a close atmosphere with fire heat. If green fly makes its appearance it must be subdued at once by fumigation, but in this matter care will have to be exercised. A moderate dose repeated two or three times will be much better than one extreme fumigation, for by the latter plan the remedy would be worse than the disease, as it would spoil the foliage.

A word or two on seedlings. Seed may be sown at the present time in a seed-pan, and be placed in a cool house or pit. The soil must never be allowed to become dry, or the seeds will not vegetate. Some cultivators sow as early as March, but that is with a view of having the plants in bloom at Christmas, at which time they are often very useful, but are never so fine as in spring. The same cultural remarks apply to the seedlings as for the offshoots. Anyone feeling inclined to grow for exhibition purposes must not rely on seedlings, but had better buy named sorts from the growers.

Thrips will occasionally attack Cinerarias; in that case fumigation is the best remedy, but they will take more killing than green fly. As I have before said, better fumigate gently two or three times than give one overdose. A still night is the best for the operation. We sometimes syringe the outside of the house or frame during the time the fumigation is going on. This has a tendency to close the laps of the glass, thereby preventing to some extent the escape of the smoke. After smoking the house or frame ought not to be opened before the following morning.—G. R. Allis.

ROYAL HORTICULTURAL SOCIETY.

June 4th.

An adjourned special General Meeting of the Royal Horticultural Society was held last Friday in the Council-room, South Kensington, for the purpose of receiving a communication from the Council respecting the future prospects and condition of the Society, and to receive an answer to proposals made by the Council to Her Majesty's Commissioners. The chair was taken by the President of the Society, Viscount Bury. Amongst the members of Council present were Dr. Kellock, Sir Coutts Lindsay, Bart., Mr. Henry Webb, Mr. Little, Mr. Dobree (Treasurer), and the Hon. and Rev. J. T. Boscawen. Amongst the general body of the Fellows were Mr. G. F. Wilson, Mr. W. A. Lindsay (late Secretary to the Council), Mr. H. S. Godson, Mr. Shirley Hibberd, Mr. John Fraser, Dr. Denny, Dr. Pinches, Mr. W. E. Rendall, Mr. W. Pownall, Mr. Haughton, Sir Alfred Slade, Bart., Sir Alexander Gordon, Bart., Mr. Guedalla, Mr. Andrew Murray, &c. Several ladies were present, and the utmost interest was evinced in the proceedings, the Meeting being perhaps the longest of the Society ever held. Although at times a good deal of feeling was displayed, the proceedings on the whole were, under the able presidency of Lord Bury, conducted with good temper. The Meeting lasted from three o'clock until nearly six.

The Assistant Secretary having read the advertisement convening the Meeting,

The Chairman, who was slightly cheered on rising to address the crowded Meeting, said:—Ladies and Gentlemen, I think the best way of commencing the proceedings of this Meeting is to read to you a letter which has been received from Her Majesty's Commissioners in answer to the proposals which have been made to them by us. It will be in your recollection, ladies and gentlemen, that ten days ago our Meeting was adjourned to this day in order that we might consider the answer—if any answer was received in the meantime—from Her Majesty's Commissioners. At the time of our former Meeting we were not in possession of the views Her Majesty's Commissioners entertained as to the proposals made by our Society, and now, having heard what Her Majesty's Commissioners have to say, it will be my duty briefly to review the position of the Society, to tell you the position in which it stands with Her Majesty's Commissioners, and then to exchange with you some deliberations and take counsel as to what our future action with respect to the Society is to be. First, I will call upon the Secretary to read the reply which we have received from Her Majesty's Commissioners [hear, hear].

Mr. Hibberd said he thought it would be very desirable that the proposals of the Society should first be read [cries of "hear"].

The Chairman said he was taking the course he thought best for conducting the business of the Meeting [applause].

Sir Alex. Gordon.—Well, I beg to move, "That the proposals of the Society made to Her Majesty's Commissioners be read."

A Fellow in the body of the room seconded the motion, and it was carried.

The Chairman said as that was so he should make a statement which he thought might be advantageously done after the letter of Her Majesty's Commissioners was read. The noble Chairman was then about to read the letter in question, when,

Mr. Godson rose, and amid some cheering asked that the

proposals of the Society should first be read, and said he begged to move that they be read.

Amid some confusion this was seconded.

The Chairman said that if Mr. Godson's motion was carried he should resign his position in the chair [loud cries of "no" and some interruption]. He should certainly make the speech, and adopt the course which to him seemed fit [cheers].

Sir Alfred Slade.—Let me just ask a question [uproar].

Mr. Guedalla in the noise was understood to say that he had been accustomed to public business for fifty years, and that in his opinion the proposals ought to be read.

The Chairman observed with some warmth that he should not make the critical statement he had to make under the dictation of anyone ["oh!" and more interruption].

Mr. Shirley Hibberd.—There is no dictation whatever. Why not let us have the proposals before the reply? [cheers].

The Chairman.—Perhaps you will make my speech [uproar].

Sir Alfred Slade.—Although I agree it is desirable the proposals should be submitted to the Meeting, and that if any gentleman chose to read the reply to them first in the course of his speech, it would be so much worse for his speech. Still it is unusual to interrupt a gentleman in making a speech, even if he puts the cart before the horse [cheers and laughter].

Several Fellows rose to address the Meeting, but yielded to Sir Coutts Lindsay, who said:—We have done everything we could to come to an arrangement with the Commissioners. There are six schemes, and not one, and Lord Bury thought we should come to the sequence. If you thought right of it, it was competent for you to see all the schemes, and really the Chairman is anxious you should see all the schemes we have brought forward [cheers].

Mr. W. A. Lindsay.—Let them be read [cheers and interruption].

Sir Coutts Lindsay.—Let them be read in due course [much confusion].

Mr. W. A. Lindsay.—May I venture to suggest that you will read the substance of the letter instead of reading it verbatim? [cries of "no"].

The Chairman.—In all my experience of public meetings it has never been my fate to find a meeting at which the person who was elected to preside over its proceedings was not allowed to make his statement as he wished to make it [cheers]. I beg respectfully to say I shall make that statement in my own way, and as I think best, or I shall leave the chair. [The Chairman took up his hat as if to carry his threat into effect, and this was followed by loud cries of "no."]

A Fellow.—Let the Secretary read all the letters.

Mr. Guedalla.—The Chairman can embody them in his speech [hear, hear].

The Chairman.—That is the very thing I proposed to do [cheers]. If you do not let me make my speech in my own way how am I to make it at all? I assure the Meeting they would be in possession of the whole case if I were allowed to go on [cheers].

Mr. Haughton.—All we objected to was the reading of the reply before the proposals [hear, hear]. The correspondence ought to be placed before the Meeting in proper order [applause].

The Chairman.—If the Meeting chooses to say that I will do the best I can [cheers]. I wish to state Her Majesty's Commissioners have refused the proposals made them. I intended to place before you the way in which they have done so, but I honestly confess this interruption has fairly scattered the course of my thoughts; and although I should like to present to you as well as I can, and as briefly as I can, the position of the affairs of the Society, rather than observe upon an attempt made by ex-members of the Council, who, having quarrelled with the Council, could not remain in it, to ——

Sir Alexander Gordon.—Had not this be better avoided? [cheers].

The Chairman.—Well, I deprecate the course taken without hearing any of the facts discussed on the one side or the other, and I think it very unfortunate. Honestly, ladies and gentlemen, I confess my ideas are so scattered I very much doubt whether I can make the satisfactory statement I could have otherwise made to you. I will for the moment content myself with a brief review of the position of the Society at the present moment, and then in a few words give a parting counsel to the Society. I say a "parting counsel," for if I had been allowed to read that letter it would have been observed that the way in which our negotiations have closed with Her Majesty's Commissioners led conclusively in my mind and in the minds of several of my colleagues to the opinion that we could do no further good for the Society in resuming negotiations with Her Majesty's Commissioners. It is quite possible that others who may succeed and replace us may be more fortunate in establishing good relations between Her Majesty's Commissioners and the Royal Horticultural Society. But, for myself and colleagues, I can only say, with all respect for the Society, I shall decline to resume or continue these negotiations. Therefore I and some of my colleagues propose to resign into your hands the trust you were good enough to give us some time ago, and we ask you to select others who may have better fortune in dealing with Her Majesty's Commissioners than we have had. I should like to go back for a few moments to the origin of the Society. After the Exhibition of 1851 the Commissioners of that Exhibition, with the great and illustrious Prince Consort at their head, found themselves in possession of a very large sum of what was in fact public money, and it occurred to His Royal Highness the Prince Consort that the surplus of the funds arising from the Exhibition could not be better applied than in promoting science and art in every way attainable. Hence the gardens scheme was inaugurated. This South Kensington estate was bought and vested in trustees on behalf of Her Majesty's Commissioners of the Exhibition of 1851 for the promotion of science and art for ever. The place in which we now sit, and the gardens we now have under lease, was at that time wild waste ground. It is now surrounded by houses of great pecuniary value, and moreover it is of great value as one of the lungs of the metropolis [hear, hear]. There are two things essential to the consideration of this part of the question, especially to the whole of the west end of London—that this shall not be enclosed, and shall be preserved as an open space for ever; and another is that the Royal Horticultural Society has, by means which I will explain to you, or rather sketch to you, become possessed of a very large interest in this plot of land [hear, hear]. His Royal Highness the Prince Consort desired that this wild land should be beautified and adorned according to a plan which His Royal Highness himself designed, and he set about carrying out his design for the furtherance of science and art. He turned to a Society then pursuing the even tenor of its way at Chiswick, doing great service to horticulture, but not as I believe—for it was not in my time—in the enjoyment of a large revenue. His Royal Highness asked the Society to accept a charter and become tenants of this part of the grounds under certain conditions, and these conditions were that the Royal Botanical Society and the Royal Horticultural Society should expend at the outset £50,000 on the decoration of the grounds of which they became possessed. Money must be obtained for that purpose somehow. The Gardens were already mortgaged to Chelsea Hospital, and therefore could not be made available for the requirements of the Society. That statement rests upon the authority of my predecessor in this chair—the Duke of Buccleuch. (The Chairman read an extract from the speech of the Duke of Buccleuch at a Meeting held the 29th March, 1873). Well, continued the Chairman, I was not aware the grounds were mortgaged, but I may take the fact as substantially correct.

A Fellow.—There is no doubt about it.

The Chairman.—Well, the gardens being thus heavily mortgaged, what security could be given to anybody who would step forward and find the money for the beautification of these gardens? I hold one of the original debentures issued under the control of Her Majesty's Commissioners. Anyone who is fortunate enough to possess such a document will see that he has not obtained any security on the gardens, but upon the receipts [hear, hear]. Now, we must consider the attitude of mind the Commissioners and His late Royal Highness were in. The Exhibition had succeeded beyond anyone's expectation. It was expected that a new Eldorado—a new Fortunatus's cap had fallen upon the Commissioners. It was thought we should have made so much money that, when the £2100 rent was paid, and the debenture interest was paid, there would be a large surplus to be divided. This was the enormous estimate which then existed in the minds of the late Prince Consort and of his advisers when the debentures were issued. The debenture-holders no doubt shared in the sanguine expectation of His late Royal Highness, and believed the garden receipts would be ample to pay the interest, and in part the capital. International exhibitions, however, were held in Paris, New York, and St. Petersburgh, and the Eldorado was found to be a limited one—one having small boundaries; international exhibitions became a drug in the market, and then we had from the Exhibition of 1851 the bathos of the annual exhibitions held in the railway sheds at the head of South Kensington [hear, and laughter]. Great results were expected from these exhibitions, but people were deceived, and the result was that it was found the debentures rested upon no solid foundation. But I believe the debenture-holders will receive their money. But why? Because of the great names upon the security of which those funds were supplied; because no part of these gardens has been devoted to the uses of the Royal Horticultural Society itself, the whole property being at this moment vested in the landlords; and because the whole profits have been acquired and used by the Royal Commissioners [cheers]. It is for this reason I say Her Majesty's Commissioners cannot, and public opinion would not allow them to let these debentures remain unredeemed [cheers]. That is our security for the payment of these debentures. I am obliged unreservedly to express my views about these debentures, and tell you frankly we are not responsible for these debentures or the way in which they were raised, and which are such a heavy charge upon us. £50,000 of debenture bonds with

their interest forms the main liability of this Society; but it is because we look to the way in which these debentures were raised that the Council which has now the honour of addressing you through me, and because our lease is terminable at any moment, and that the whole usufruct of that money goes into the pockets of the Commissioners, that we think they are the people to whom the debenture-holders must turn. The interest of the debentures the Society will pay so long as they can, but the Commissioners should assist us in some way so as to provide for the satisfactory payment of the debenture debt. With that view whenever we approached the Commissioners we invariably assumed that they should take over the interest at least of the debenture bonds. I have detained you not too long, because it is a matter of the most vital importance respecting the debenture debt of the Society. And now I come to the time when, as I said, the International Exhibition had given place to the annual exhibition in those rows of sheds upon these grounds. By that time the principal power of Her Majesty's Commissioners was exercised by the gentleman who has done so much to advance science and art—I mean Sir Henry Cole. I believe the result of that man's remarkable and magnificent scheme over the way will remain an everlasting monument to his genius; but parents are rather fonder of their own children than of other people's bantlings, and Sir Henry Cole, I think, treated the Royal Horticultural Society rather hardly. When an arrangement was being come to in 1863 the proposal he framed was that every interest connected with the Royal Horticultural Society should be vested in the Commissioners of the Exhibition and not in the Society itself. I was not then a member of this Society, nor even a subscriber. I was not a member when my honourable friend Sir Alfred Slade organised the opposition to the then existing Council, which procured its resignation. But after that resignation was effected my friends and myself were called in as financial doctors of the Society, and I beg to assure you in this my farewell address that we with entire singleness of purpose have devoted ourselves to the interests of the Society. I found upon first joining the Society that it was believed that the Society was divided into two arms—the horticultural body pure and simple, and the South Kensington residents. I fought against the belief, but I confess I was vanquished by the belief. The Society is divided into two sections, and it is to be regretted. I am sorry to say I know little of botany, but I consider myself the representative now of the Royal Horticultural Society in its entirety. I have said this much to show that we have had to face a remarkable state of things immediately after our accession to office. Myself and colleagues were called upon to make the best we could of the circumstances, and I shall be able to show you that we resign our trust into your hands in a better, or at least as good a condition, as when we took possession of it. The debts of the Society on the 1st of January, 1873, were £6273, and on the 1st of January, 1875, they were £4887. Our total liabilities are not above a half-year's income of the Society, while the assets far exceed our liabilities, so much so that we could get on very well. Although we may have to starve our Society in a great many necessary things, still we are paying our way at this moment, and will pay it until the end of the year. The prizes won at our last show will be paid this or next week [cheers]. Prizes for future shows will be provided; and though like honest men we are narrowing our expenditure to the lowest limit, we are still paying our way. It is quite true that we owe a debt of £5000, and unless it is paid we shall find ourselves in financial difficulties. That debt was not incurred either by this or the last Council, and with respect to the debts of 1873 to 1875 I challenge anyone to say whether we have not discharged our part well. We have been made the successors of a debt placed upon us. Now, gentlemen, I come to the point when we took office. At that time, the scheme proposed between the Commissioners and ourselves having failed, it was our duty to find other bases of schemes which would be acceptable to them and enable us to live in amity with them. At that time the great position of Commissioner was accepted by a most active individual, Sir Henry Cole. Well, the International Exhibition child must be fed and kept up at any cost. Sir Henry Cole looked after his own offspring, and we were to go to the wall [laughter]. We were not wanted, but our grounds were wanted for the International Exhibition, and that is the long and the short of it [cheers and laughter]. We found it impossible to approach the Commissioners, and hence the Council could do nothing. The Council was told the sin of illegitimacy was upon them; but two years afterwards the Council received an intimation from the Commissioners, that having found the Council were now in a legitimate position, they should be happy to deal with them. What brought about that change? It was that Sir Henry Cole had ceased to be a Commissioner, that the annual Exhibitions had ceased, and the reasons why the grounds were desirable had passed away from the Commissioners' minds [loud cheers]. It was quite easy to see that it was from that moment the interest of Her Majesty's Commissioners to be on good terms with the Council. We were secure in the possession of the gardens. If we were turned out the Commissioners would either have to build upon the gardens—which public opinion would not sanction—or the Commissioners must devise some scheme to support the gardens. Were they to find the money out of the revenue of the Royal Commission? The gardens are unproductive, the annual subscriptions of the Fellows and the entrance money being the only means by which the gardens can be made productive. We have several means of keeping the gardens: we have a large organised body of three or four thousand Fellows; we have a great machinery at the disposal of Her Majesty's Commissioners, and we keep up the gardens for the benefit of the Commissioners [loud cheers and cries of "no, no"]. If we were removed the Commissioners would have to find from £2000 to £3000 a-year to keep them up, or at least a considerable sum, and that I believe does not suit the books of Her Majesty's Commissioners, who, if report is true, are not in the possession of very much ready money [loud laughter and cheers]. Under all these circumstances we approached Her Majesty's Commissioners with considerable confidence. It was not, however, until the early part of this year we received an intimation they were ready to treat with us, just after the time of our annual meeting in February. We were ready at a moment's notice. When Her Majesty's Commissioners said they recognised the legitimacy of your Council, we told you we had received an assurance from Her Majesty's Commissioners which led to the highest anticipations, and we said to you we hoped soon to arrange a plan by which the Society would be relieved of its difficulties and placed in a good financial position. I pledged myself to meet the Commissioners and to come to you at a meeting to be called for that purpose with some such plan. It was decided that it would be better for two of the members of our Council, Sir Coutts Lindsay and myself, should discuss the basis on which we could form negotiations. That meeting was held, and has been since treated less as a private meeting than was our original intention. At that meeting three alternative proposals were made by Sir Coutts Lindsay and myself. These proposals I will summarise. We said we would abandon the lease on this condition—first, that we should pay rent. Now that was a preliminary and informal meeting held on the part of Sir Coutts Lindsay and myself representing the Council, to arrange the business to be afterwards decided by the Council. This was not to be binding on the Society unless it was approved of by you. We said we would pay a rent of £250 per year and keep up the gardens, and that that would be better than to pay a rent of £2400 every five years. Our lease was to be terminable in the year 1881, or at any time that we did not pay the rent. Then another proposal was that we should make the payment of the £2400, or that our lease should be forfeited; and we also said if the Commissioners did not like that we had two other proposals—one that we would surrender the lease to the Commissioners if they would give us twenty days for exhibition in each year, and undertake our debenture debt [loud cheers]. A third proposal was that Her Majesty's Commissioners should give us leave to make the skating rink, give us possession of the leasehold property of the Society, and allow us to use the French annexe, our idea being to make an aquarium for the study of pisciculture to enable us to do the best we could with our property [cheers]. These proposals having been made, we were afterwards informed that the Commissioners having deliberated upon them found that the first was the only one which was in any way admissible, and that without approving of it they would be prepared to receive further details of that scheme. Upon that I wrote a letter to Lord Granville embodying the details. I may now say, as I see a representative of the Messrs. Prince present, that in our negotiations with those gentlemen we invariably received the most handsome treatment at their hands; in fact, they looked more to the interests of the Society than they did to their own [cheers]. However, as to the first scheme the Commissioners found fault with our statement of income and expenditure, and made their own statement of our financial position, with which we could not agree; and the Commissioners then wrote that on this ground and on other grounds the Inquiry Committee regretted they could not recommend the Commissioners to agree to the proposals, but that they desired that the Council would make other proposals. In answer to that the Council wrote that they believed the Commissioners were quite willing to help them. They had made other proposals, had shown their position, and if the Commissioners could tell them how to mould their proposals the Council would be willing to make such as they thought would be acceptable to them [hear, hear]. We therefore asked the Commissioners to tell us what proposals they would accept; and to that the Commissioners answered that it was not their business to make proposals, that the Council might try again, but they could not tell us what proposals would be acceptable. Now comes a very difficult part of the task, because, as you are aware, private negotiations often tend to more business conclusions than more public negotiations. I as President felt bound to try and ascertain what proposals would be acceptable to Her Majesty's Commissioners. Well, as

a detective would say, "on account of information received," we presented another atatement, and I regret to say that proposal met with non-acceptance on the part of Her Majesty's Commissioners. You know, ladies and gentlemen, that there are always two parties to a bargain, and that you may bring a horse to the water, but you cannot make him drink, and so you cannot make an arrangement between two parties who are not anxious to enter into it. We regret the Commissioners refused our propositions; we do not blame them, but think them in the wrong. They said they were not satisfied with the statement of our financial position, and said they would not enter into negotiations with us unless we could show we were in such a pecuniary position as would enable us to carry on swimmingly the business of the Society. We drew up a statement to show what the financial position of the Society would be if our proposals were accepted. In order that there should not be any difference of opinion as to the sum at which we were to put down our liabilities and our means as well, we invited General Scott, accompanied by Mr. Richards, to meet Mr. Dobree and Mr. Pugh, accompanied by Mr. Davenport. These gentlemen arrived at the result that the facts we placed before them were not in error and not in dispute. We did everything we could to satisfy the Commissioners, and at last we submitted them the proposal which I shall ask Sir Coutts Lindsay to read.

Sir Coutts Lindsay read the proposal as follows:—

"That the Royal Horticultural Society would hope to be placed in possession of that part of the French annexe which is built on ground now leased to the Royal Horticultural Society, and that the Society should be allowed the joint use of the orchard house entrances.

"If this proposal be adopted by Her Majesty's Commissioners, the Council anticipate that an increase in the Society's income would follow large enough to balance their income and expenditure, and to enable them with due economy to offer still greater advantages than heretofore to scientific horticulture.

"The skating rink would bring in by way of rent £1000 a-year, besides many new Fellows. It was one of the provisions of the agreement lately stopped and still open for acceptance by the Royal Horticultural Society, that all members of the skating rink were to be Fellows of the Society before being eligible for becoming members of the skating rink. A considerable augmentation of income under this last head is confidently expected, though there is no data whereon to form a basis of estimate. If the funds of the Society would admit of it—as they probably would in the event of these propositions being accepted—the Council would use every effort to afford additional advantages to horticulture, with respect to the exact nature of which it is their intention to confer with eminent members of the horticultural world."

The Chairman in continuation said, That proposal was enclosed in a letter, and in that letter we stated that the Council could not admit the accuracy of the figures stated in the letter of the Commissioners, that they were not in possession of the views of the Commissioners, and that as they had a sincere desire to "hit" their views they enclosed an alternative scheme; and that if the Commissioners would only tell us they approved of the one or of the other, or admitted one or the other, then the Council would propose a scheme to the Fellows at the adjourned Meeting of the Society. It was under these circumstances our Meeting was held, but upon the day of that Meeting no answer had been received. The second or alternative scheme was:—

"That the purely horticultural Fellows of the Society shall take the entire control and management of the Chiswick Gardens, and that the South Kensington residents shall charge themselves with the maintenance of the South Kensington Gardens, and have the control of those gardens. The amount of subscriptions in each case, and the apportionment of the burdens of the Society's debts, being left to be fixed by a committee chosen out of the general body of the Fellows and representing the Royal Commissioners, the Horticultural Society, and the resident Fellows. Shows and exhibitions to be held at South Kensington as heretofore. This scheme would leave the scientific horticulturists in possession of Chiswick for their operations, or would give the management of the South Kensington Gardens to those who paid for them, and would yet retain to the Royal Horticultural Society the use of the gardens for shows and similar purposes. To carry out this it is proposed that there shall be two rates for subscription, (A) one of which shall admit to the South Kensington Gardens alone under certain restrictions, hereafter called South Kensington Fellows. (B) The other shall admit to Chiswick and the Royal Horticultural Society's Shows, hereafter called Chiswick Fellows.

"The subscription A to be fixed at such a sum as shall be deemed sufficient to keep up the South Kensington Gardens, the permanent buildings, and a portion of rates and taxes accepted. Subscription B shall be fixed at such a sum as shall be deemed sufficient to keep up Chiswick Gardens, and to pay the expenses of the shows. The profits of the shows held at South Kensington to go to Chiswick. The Council of the Society to be increased, and divided into two permanent committees; one for the control of interior economy of South Kensington, the other the sole control of Chiswick, and a central Council composed of members from each Committee to regulate the general affairs of the Society.

"The other conditions of this scheme summarised are as follows:—

"The general funds of the Society to be fairly divided between the two branches of the Society.

"An agreed portion of the funds to be kept by the central Council for the payment of the debenture debt and general debts of the Society. Her Majesty's Commissioners to be asked to keep the permanent buildings at South Kensington in repair.

"Her Majesty's Commissioners to sanction the erection of a rink."

Then the third scheme was as follows:—

"The Fellows two-guinea subscriptions to be raised to three guineas, and the £4 4s. subscriptions to £6 6s., for a period of, say, three years. The tickets to be transferable. All entry fees to be abolished. Personal tickets of £1 1s. each to be issued to persons *bonâ-fide* belonging to the gardening profession, and to other persons resident without a given radius from London, giving the Fellows the privilege of attending all the exhibitions and Wednesday Committee Meetings of the Society. To ask the Commissioners to lend the Society the sum of £6000 at 4%, to enable the Society to pay off outside current liabilities. The increase of income under these new rates of subscriptions would be about £3991, which, added to the other estimated income, would give a total income of £13,091.

"All entrance fees to be abolished. A letter from the Assistant Secretary covered these proposals."

That makes six schemes which we have proposed to Her Majesty's Commissioners. I now come, ladies and gentlemen, to the letter of Her Majesty's Commissioners, and here I take the opportunity of apologising for any warmth of manner which I displayed at the earlier part of our proceedings [cheers]. Now I shall read for you the letter of Her Majesty's Commissioners refusing our proposals. It runs thus:—

"Offices of Her Majesty's Commissioners for the Exhibition of 1851.

"1st June, 1875.

"Sir,—I have to acknowledge the receipt of your letter of the 10th of May, wherein, after referring to the non-acceptance by the Special Inquiry Committee of Her Majesty's Commissioners of the proposals made on behalf of the Royal Horticultural Society by Lord Bury and Sir Coutts Lindsay, certain further propositions are submitted by the Council of the Society for the consideration of the Committee. I have also to acknowledge the receipt of your explanatory letter of the 20th of May. In reference to the passage in your letter of the 10th of May, in which you state that the Council cannot admit the accuracy of the figures given in my letter of the 5th of May, I am to state that the whole of the data made use of in reviewing the financial prospects of the Society (with the exception of the statement for repairs) were furnished by the deputation. But since the difference between the amount of the liabilities now given by you and that stated by the deputation is not so important, compared with the total deficit, as to have influenced the Committee in coming to a decision conveyed to you, this question need be no further debated.

"The Committee regret that they must decline the further proposals made to them in your letter of the 10th of May. The Commissioners are still desirous to assist the Society as far as they can do so consistently with their duty; but the Committee having in view their responsibility as trustees of the public funds, cannot recommend that they should consent to contribute towards the maintenance of the Society in the modes specified. It is not apparent to them that the concession even of the large assistance requested would be productive of advantages to horticulture, or in any way benefit the public. In the final paragraph of your letter of the 10th of May the Council ask the Committee what propositions they could recommend for adoption by the Society in the true interests of horticulture. I am instructed to reply that the Commissioners do not think it to be for the advantage of the Society that they should interfere with the management of its concerns further than absolutely needful. The Committee have had their attention called to the proceedings of the General Meeting of the 25th of May, and they observe with much regret that serious differences still continue to exist within the body of the Society. The Committee direct me to state in conclusion, that before recommending any proposition from the Society for assistance by the Royal Commissioners they will feel it incumbent upon them to satisfy themselves that the differences between the various sections of the Society have been composed; that the advancement of horticulture will in future be made the chief object of the Society; and that steps will be taken to put the Society financially on a more satisfactory footing.

"I am, Sir, your obedient servant,

"Henry Y. Scott, *Major-General.*

"The Secretary Royal Horticultural Society."

With reference to that letter, it closed our negotiations with the Commissioners. I may remark, however, that the Commissioners still say it is their wish to offer some aid to the Society if they can do so. For my own part I shall be quite willing to accept that assurance provided some other member of your body is the negotiator. I hope my successor may be more fortunate in his negotiations with Her Majesty's Commissioners than I have been. With regard to the remarks made as to the meeting of the 25th of last month being marked or distinguished by considerable discussion, I should like to tell Her Majesty's Commissioners that if they think a body of three thousand men are to possess a unanimity never known in the whole world, and that if they are to wait until we shall have that unanimity, they must really expect that the lion will lie down with the lamb [laughter]. Unless they are of that opinion the "composing" of the differences they speak of is a long way off [cheers and laughter]. I think some differences of opinion must exist amongst the members of the Commission themselves [loud cheers], because they are always saying they are willing to give us assistance, but the motive power in General Scott's hand is stronger than the large amount of sympathy we hear of with the Royal Horticultural Society [cheers and laughter]. It is to be hoped our successors will find themselves better able to "compose" the differences between the two bodies than we have been. I may say at once I am afraid we should not be able to frame any scheme which would be acceptable to Her Majesty's Commissioners. Still, I am willing to accept the statement they are willing to do what they can. I am also willing to say the Council have done all they could to frame such a scheme as they thought would be acceptable to Her Majesty's Commissioners. I now come to a matter somewhat personal. Four members of Council—Sir Coutts Lindsay, Mr. Dobree, Mr. Hume, and myself consider we should be only acting in the interests of the Society, with a due regard to our own dignity and position, and also to the trust which you have reposed in us, by surrendering unto your hands that trust; and to persuade you if we can do so—as I trust I have done—that we have not been either wrong or remiss with respect to your interests, and that we have done all we knew

how to do [cheers]. We feel the only honourable course is for us to give the opportunity to others to do what they can ["no, no"]. We will help you as well as we can, and all minor differences shall be sunk [cheers]. We will do all we can to relieve the Royal Horticultural Society, as far as it rests in us, from its difficulties, but we consider it our duty to resign our offices. I resign, Mr. Hume does so, Mr. Dobree does so, and Sir Coutts Lindsay does so. I have to thank those members of the Council who do not agree with us in this for their support. I never found in my life a more active or unanimous Council, or one more devoted to the duties of their office. Some of my colleagues do not think it their duty to resign their offices, because, as I believe, they think they were appointed by one section of the Society, and I do not think they ought to resign until that section takes the power out of their hands [hear, hear]. The horticultural Fellows have been in the majority, and therefore these gentlemen do not feel it their duty to resign. I will, if you will permit me, give you a parting word of advice. My own belief is that the only way to save the Society is that you should divide the two bodies, the pure and simple horticulturists, and the Kensingtonians as they are called [cheers]. Let the Chiswick Gardens be put in possession of a purely scientific body. The funds required would get still smaller, and I think the Fellows who live around these gardens ought to pay for their maintenance [hear, hear]. Let us divide for the common good. Let the scientific horticulturists go to Chiswick, and keep the "Kensingtonians" at South Kensington. That is a scheme you can carry out without the sanction of the Commissioners, and by reducing your expenditure you can keep within your income. I do trust whatever course you pursue may be for the benefit of the Society, for its relief from the embarassments which lie upon it, from its difficulties which are by no means insuperable. Pay your rent next year, and then you can keep possession. I must say before I close that what the horticultural papers stated was not altogether fair. It was never intended by anything which fell from me, that the idea that the Society was insolvent should be conveyed. In the first place, if I said so it would not be true.

Mr. Godson.—It is a pity you ever mentioned it.

The Chairman.—Well, that may be so. I may say that the claims brought against us have been paid. I beg to conclude this statement with a hope that you will find our retirement conducive to the benefit and honour of the Royal Horticultural Society [cheers].

After a short pause,

The Chairman again rose, and said that many members of the Society had expressed their wish to subscribe money to relieve the Society from its embarrassments. Mr. Ricketts promised £25, Mr. Godson £25, Mr. Paul £100 a-year for ten years on the condition that nine others would do the same [cheers]. Mr. Bull promised £100 in aid of our Show, and Mr. Dobree said he would give £100 [cheers].

Mr. Kellock said that as a horticulturist he did not feel it his duty to resign his seat at the Council [loud cheers]. Neither do the horticultural Fellows on the Council think it their duty to resign [cheers]. They respected the South Kensingtonians, but literally they had nothing to do with them [laughter]. On that ground the horticultural members of the Council did not tender their resignations [cheers].

Dr. Denny said the Meeting had to thank the noble lord for his able statement, and it could not be without regret that they heard it. The Council had come in as a Kensingtonian Council, and as a horticultural Council they had failed. It must be admitted, upon all hands, that the horticultural part of the Society was not in the position it was when the present Council took office. The horticultural Fellows were becoming disgusted, and were leaving the Society wholesale, and more than that, the attendance at the Gardens was falling off. In fact, under present management the Society would fall to pieces in a few months [hear and cheers]. The Council might say they were paying their present prize money, but why? Because no one was exhibiting [hear and laughter]. The present Council took office in opposition to the Royal Commissioners [cries of "no"]. Why, the Council turned out Royalty—they turned out Prince Arthur.

A Fellow.—Not at all—don't let that go forth—Prince Arthur resigned [hear, hear].

Dr. Denny.—He could not remain in office under the condition of affairs (cries of "time"]. I think our thanks are due to those members of the Council who do not resign [cheers].

Mr. Guedalla said the deadlock was entirely due to the shuffling conduct of Her Majesty's Commissioners [cries of "no" and "hear"]. Yes, they kept the Society in a fix for upwards of twelve months, and then in the month of February they came down and said they were ready to come to an arrangement. The Council had placed most excellent plans before the Commissioners, and what right had the Commissioners to indict their acts? The last plan proposed is the only one to work any real substantial good, and that is to separate Chiswick from South Kensington. He was extremely sorry to see these members of the Council resign, but it was really the only manly course open to them [hear, hear].

Sir Coutts Lindsay wished, before he left his seat on the Council, to express his extreme satisfaction at the way in which he had been met by all the members of the Council, and by the Fellows generally. He quite endorsed what Lord Bury said with respect to the Society. As to the charge brought against the Council of not having fostered horticulture, the answer was that the Council had neither money nor means. Lord Bury had very ably shown them the misfortune under which their Society had laboured. They never had funds to meet the expenses placed upon their shoulders by the Commissioners, and so the Society had been brought to a position—if not of bankruptcy—of great impecuniosity. It would be better after all to divide the two interests which existed in the Society. Let those who took most direct interest in horticulture take its management in their own hands. As regarded the resignations, he might say that he believed every gentleman on the Council acted to the best of his judgment. Mr. Hume who was not able to be present had written a letter, and he (Sir Contts Lindsay) would say with entire sincerity that those who retired did so with no feeling of soreness, and with the belief that they had at all times received the support of their colleagues and of the Fellows in general [cheers].

Mr. Dobree expressed his thanks for the support he had received from all connected with the Society. He was sorry his time had not been of more use to the Society than it had been, but he could not afford to give any more time, as he was engaged in commercial pursuits. Mr. Hume much regretted he could not attend that Meeting, as he had to be present that day at a School-board in Norfolk.

Sir Alfred Slade remarked that, according to the sixteenth bye-law no business except that for which the adjournment was made could take place. Therefore the Meeting was incapable of accepting the resignation of the members of the Council, or to appoint their successors. He regretted very much that there should be any reason for the resignation of the members of the Board who had tendered it.

The Chairman said Sir Alfred Slade was right. Another meeting would have to be called to deal with the resignations. That was strictly in accordance with the bye-law which he had quoted. The simple fact was they would have to call another meeting.

After a discussion about the bye-law,

The Chairman said he and his colleagues had not yet resigned, and perhaps they should not [loud laughter].

Mr. W. A. Lindsay said he regretted that he should have made some remarks upon the occasion of the last meeting which created or introduced a feeling of bitterness. All he could do was to express regret for these expressions [cheers]. Without going into any further matter, he wished to say that he believed the state of the Society was perfectly sound, and he felt it could be reorganised, but only by reverting, both actively and mentally, to the part represented by the picture over the Chairman's head, painted at a time when this Society was renowned for its science, but not for its local fashion [cheers and loud laughter].

The Chairman.—I have nothing further to say than that the Meeting is at an end.

Mr. Shirley Hibberd.—Have you taken your farewell of us? [cries of "no"]. Very well, then; he has made his farewell speech, and you know he has done good hard work, so give him your hearty thanks [loud cheers].

Mr. W. A. Lindsay seconded the vote of thanks to the Chairman, and then the protracted proceedings closed.

AURICULAS.

At the National Auricula Show in April, and subseqnently in the pages of the Journal, the question has been raised whether or not the florist Auricula, when under exhibition, should be allowed some stick or prop to its flower stem. With "An Old Fancier," and with all the northern growers to whom I have named the subject, I sincerely hope that this gratuitous disfigurement may never be sanctioned.

It should never be necessary. If the stems do not carry the trusses well there is, as a rule, blame to the grower, and he ought to bear the consequences. He has allowed the stalks to rise weak or become drawn for want of air to make them stiff and hardy. A few varieties—*e.g.*, Blackbird, Catharina, Moore's Violet, and Imperator are given to growing long on the stem, and this is a fault in such varieties, and makes its mark. Even these, however, when grown in the airiest part of the frame or house, may be so far managed as to require no stick. It should not be forgotten that one decided property in a florist Auricula is that the stem should be able to carry the head well, and therefore to permit artificial support is so much allowance to ill growth, and so much leniency to ill habit, to the commensurate disparagement of better management and qualities. For my own part I should be ashamed to show an Auricula

that could not carry its own head. Our rules against sticks to stems I have always read as rather a caution against leaving some avoidable mark of identification during the judging than as a prohibition of a practice calculated to help a top-heavy truss against specimens to which every natural advantage had been freely accorded in order to have them able-bodied. It cannot be said that Auriculas require sticks because of a long journey to the show. The plants can be so carefully packed and bound up in damp moss, and the stems can be so steadily secured by a stick and cotton wool, that no drooping or straining of the stalk is possible. I have a very tedious journey with my plants, and this is my experience.

Mr. Douglas, remarking that stems will rise at almost any angle from the plants, thinks sticks permissible to make them straight. I will tell him a better plan than exhibiting this contrivance at a show. Let the oblique stem be guided while rising with a short prop behind, and then, before the bloom is on, the stem will be set in better form. If it cannot possibly be made erect; the plant itself may at the show be potted aslant, to bring the truss upright. The argument that a stick, unsightly at the best, may be left in to save trouble of unpacking and repacking is probably one that few florists would think worth the using. Better take a few plants the less, in order to be able to care well for all.

You cannot give the Auricula any artificial support without spoiling the strength and elegance of its beauty. The disposition of the foliage round the stem, which rises crowned above it with a bouquet of wonderful flowers, often backed by a guardian leaf that used to shield those flowers when buds, is a form that nothing unnatural can improve; and a stick by the side of that stem is a mere wooden leg—is an ugliness that cannot be hid. This plant had better carry less weight of bloom than go upon crutches. For this, as for other reasons, I trust that sticks will not be voted-in. I submit that a clear field and no favour is here, as everywhere, the fairest play.

My own plants will have said for me that I am no advocate for cropping down to three pips such trusses as well could carry more; but in a head of incorrect pips, as well as good flowers, care should be taken not to present to the keen eye of a judge more ill-favoured than fine pips. Two bads will never make a good or count at all, except against the exhibitor; and a small truss which is correct rightly wins before a great truss that transgresses rules which are strictly the guide to precedence. There is little virtue here in mere quantity, but quantity of quality will be recognised everywhere, and nowhere more freely than in our great florist shows in the north.

Mr. Douglas was told that the premium white-edge at Manchester was a Catharina denuded to three pips. The plant was mine, and Mr. Douglas misinformed. It never had more than three, being a maiden bloom of correct properties; and the pips, though never large on Catharina, were nevertheless a shade above shirt buttons, and not exactly like threepenny-pieces.

The question is more than once asked, "Why, in point of body colour, is black so preferred in edged Auriculas? and why in Lancashire is this colour so far favoured as to make it seem no other will do?" Contrasts of a velvet black with snowy meal and the rich green edge are certainly very fine; but would not a violet or red ground colour be so too? Undoubtedly, and may we see them! But think the Auricula over, and it will be noticed that with black-bodied flowers are associated other properties in their finest order; that the black grounds have among them the purest edges, the richest tubes, the best-proportioned body colours. In them are green, grey, and white edges unruffled by rude inroads of colour dashing through, and there is also a density of ground colour, not faultily melting into some lighter shade before it reaches its limits towards the edge. Find in a red, lilac, blue, or violet body colour such a flower for correctness as Smiling Beauty, and it will not lack lovers in the north. But when with such colours we have the disappointment of a weakly-coloured tube, or irregular and insufficient edge, these faults must be laid to the flower and not at the door of a northern florist. It is just when the body colour of an Auricula is not uniform but shady, that the reproachful term of "chancy" should apply with justice, and though such a flower may be pretty, it is not so truly beautiful as that which is correct.

I have not the pleasure of growing the Alpine classes. To me their growth seems of a loose habit, and in many the stems are decidedly slender. Still, if even these could be grown without requiring sticks it would surely be better. I am loth to speak without the authority of experience or knowledge, therefore say no more with respect to these varieties. But my humble opinion of the florist Auricula is, that it ought to be shown with every feature and every outline free.—F. D. Horner, *Kirkby Malzeard, Ripon.*

MUNRO'S DUKE OF EDINBURGH CUCUMBER.

Those who require a great number of small or medium-sized fruit of good quality, rather than showy Cucumbers of great length, will find the Duke of Edinburgh the best of all sorts to cultivate. A fruit 12 to 15 inches in length is generally sufficient to place on the table of most families, and with even one plant, well grown, of the Duke of Edinburgh, there will be no difficulty in cutting a fresh fruit every day for months.

I have lately seen a striking proof of the value of this Cucumber in the attractive and well-managed garden of J. Sharp, Esq., Fairsnape, East Sheen, Mortlake, where, in a small span-roofed house, are growing six plants, three of Duke of Edinburgh, and three of Blue Gown. The whole of these plants are in the fine condition which may be expected from such a thorough gardener and excellent Cucumber grower as Mr. Young undoubtedly is. In this house Blue Gown is showing immensely, but fruit will not be ready to cut for a week to come, but the Duke of Edinburgh of precisely the same age, and under exactly the same treatment, has afforded a supply of valuable Cucumbers for five weeks. The fruit which has been cut, with the numbers now hanging, may be safely counted by hundreds.

Plants of this variety planted-out at the present time in frames made vacant by the removal of bedding plants would yield an excellent supply of Cucumbers during the late summer and early autumn months.—A Surrey Gardener.

FLOWERS AND FRUITS FOR THE SICK POOR.

You took such a kindly interest in the opening of our Mission in March, that I am sure you will be glad to hear that hitherto we have had great encouragement in the work. No words can describe what the effect has been on the suffering and sorrowing people to whom by thousands our little bouquets have been sent in workhouses, hospitals, and lonely sick-rooms in East-end courts. A letter this morning from a fever hospital says, "It is almost impossible to fully realise the unspeakable joy with which the weekly gifts of flowers are welcomed by the patients. May I venture to hope that we may still be considered worthy objects of the solicitude of the ladies of the Mission, and that our weekly flowers may be continued to us?"

It is with great regret, since the wild flowers have disappeared, that the last two weeks we have seen our supplies fall off so greatly, that though we have had more earnest applications than ever for them, we have been unable to give them. To-day, having applications for several hundreds, we have not one hundred tiny bouquets in hand. I therefore venture to write to you, trusting your influence may induce those who possess gardens and conservatories to remember the poor suffering people in our gloomy stifling streets, and send us for their use some of their brilliantly-coloured and sweetly-scented flowers, and also as the season advances some of the fresh Strawberries and common garden fruits which are so refreshing to the parched lips of the painstricken, and to the little pale-faced children who never see them growing, or taste them but when half rotten on some costermonger's barrow.

We have not as yet heard anything satisfactory from the railway companies concerning carriage. Our expenses are considerable, and we are most thankful for any subscriptions.—E. A. H., *Secretary, Flower Mission, Conference Hall, Mildmay, London, N., and Home of Industry, Commercial Street, Spitalfields, E.*

THE HORTICULTURAL CLUB.

An inaugural dinner took place at the Club house, 3, Adelphi Terrace, on Wednesday evening the 2nd, and was largely attended by the members. The chair was to have been taken by the Hon. and Rev. J. T. Boscawen, but as he was detained at the Bath and West of England Show at Croydon it was taken at seven o'clock by John Lee, Esq. After dinner the usual loyal toasts were given, and then the Chairman proposed

the toast of the evening, "The Horticultural Club and its Success." In so doing he wished it distinctly to go forth that it was in no way connected with any body, party, or clique in the horticultural world; that its object was to have a common ground where lovers of the science might meet, exchange opinions, and consult together on any matters connected with their common pursuit. He desired to couple with it the name of their Secretary, to whose exertions it was mainly owing that they were in their present favourable position.

The Rev. H. Honeywood Dombrain, in returning thanks, desired to thank both the Chairman and the members present for the manner in which the toast had been given and received, and said that he had lately received from a gentleman long connected with the horticultural world a letter in which he said that he believed it would do more to unite horticulturists than anything that had ever been started. He felt proud and thankful when he received that; and he could honestly state that nothing in what he might call his horticultural life would ever have given him greater pleasure, if it should be found that the Club would have the effect of encouraging a kindly feeling amongst the craft. He did not believe that, despite present appearances, horticulturists differed more than other people. Parsons differed, it was a truism that doctors differed, and we know that lawyers differ, but we can agree to differ; and he hinted that their Club would be the means of fostering a feeling of kindliness amongst the brotherhood.

We may add that the dinner was very well put on the table, and spoke well for the catering power of the manager. Amongst those who have lately joined are Sir Wm. Marriott, Bart.; J. Tyerman, Esq.; Col. Puckle, R.E.; G. Deal, Esq.; Bruce Findlay, Esq.; J. E. Buchan, Esq.; Wentworth Buller, Esq.; J. Cowley, Esq., and R. Warner, Esq.

THE FLOWER GARDEN.—No. 3.

The annual repetition of formal lines and masses of colour is objectionable from its sameness and monotony; designs of a more complicated form have therefore been gradually introduced. This has led to corresponding changes in the plants, for the obvious reason that for any design to be really ornamental, not only should the colours be as durable as possible, but the outlines must be clearly defined. The result is satisfactory for many reasons. We have now a greater variety of designs containing such charming combinations of colour as not long ago would have been considered impossible—plants new and old cultivated by thousands in every garden which before were only to be found in very small quantities in the hands of a few; quaint succulent plants and pretty alpine gems of minute growth but exquisite form, imparting an interest to the beds, a rich yet quiet and refined tone that was altogether wanting in the glaring masses of scarlet Geranium and yellow Calceolaria which found such favour a few years ago. As the effect is derived principally from the foliage, very little growth is required after the planting to clothe every part and detail of the design in fullest beauty, and, what is of even greater importance, it remains perfectly intact throughout the season, the rain which proves so fatal to blossom serving but to brighten the leaf tints and imparting vigour to the foliage. Thus, then, this lovely enamelling of foliage never fails us, but literally grows in beauty both under clouds and sunshine, till the falling temperature of autumn prompts us to substitute the hardier winter plants.

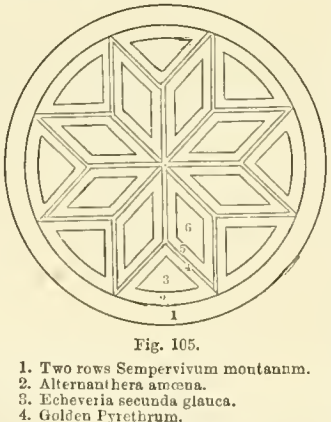

Fig. 105.

1. Two rows Sempervivum montanum.
2. Alternanthera amœna.
3. Echeveria secunda glauca.
4. Golden Pyrethrum.
5. Lobelia Blue Beauty.
6. Leucophyton Brownii, each panel to rise slightly above the blue.

There is no doubt that the facility with which the most intricate designs may now be delineated has, and still is, leading to the adoption of a much higher standard of excellence in the decoration of flower gardens than has prevailed hitherto. The old Roman mosaics are now reproduced with exquisite brightness and beauty. No finer examples have yet been produced than those which were so much and so justly admired in the Crystal Palace gardens last autumn. Plans of three of the circular beds were given with the report of those gardens in the Journal last October. Figs. 105 and 106 were also included among the designs in the circular beds upon the rosery mound. They are both copies of old Roman mosaic, and are worthy of especial notice for the novel and tasteful tracery which defines and encloses the various forms in the interior of each design.

Fig. 106.

1. Sempervivum californicum.
2. Sedum glaucum, dotted with Kleinia repens.
3. Golden Pyrethrum.
4. Lobelia speciosa.
5. Echeveria secunda glauca major.
6. Alternanthera amœna.
7. Tagetes signata pumila, pinched, and flowers kept picked-off.
8. Coprosma Baueriana variegata.
9. Coleus Verschaffelti.

Such tracing should always consist of colours that are bright and durable, its effect will then be equally telling in dividing other colours, or upon a groundwork of quieter tone. Very little attention has hitherto been given to this point. There can, however, be no question that in a large bed or wide border a groundwork of some neutral colour spreading over its entire surface, and with brighter colours apparently springing out of it, presents an appearance of chaste, pure, and refined beauty. Take for example a border or bed of the lively grey Antennaria candida skilfully embroidered with such plants as Haworthia cymbiformis, Kleinia repens, some of the Sempervivums, the pretty yellow Arabis lucida variegata, the carmine Alternanthera amœna, and the rich blue Lobelia Blue Beauty, and we have an object of surpassing beauty, infinitely superior in every respect to the more brilliant alternations of ordinary ribbon borders. Or if a design of brighter tone were required, we have but to substitute Alternanthera or Coleus for the grey to impart shades of pink or crimson, and Golden Pyrethrum or Arabis for yellow.

The increasing attention that is given to the combination of various colours in the same bed induces a decided preference for beds of simple form, plain circles and oblongs being slowly but surely substituted for the more intricate figures which experience proves to be rather curious than ornamental. This is decidedly a step in the right direction.—Edward Luckhurst.

SCENTED ROSES.

Your enthusiastic correspondent, the Rev. Mr. Camm, will be pleased to know that this year will be noted for a magnificent Rose combining the two qualities, form and perfume. I refer to General Von Moltke, a bloom of which, perfect in shape and of the most exquisite scent, I had on my desk last week. Perle des Jardins will when known supersede Maréchal Niel, it being an upright flower of splendid shape and colour. Jean Ducher is a superb button-hole Rose, its lovely wax-like petals deepening to peach colour in the centre being an acquisition. Marie Guillot as a white Rose is acceptable, its petals are, however, rather thin and watery; it will no doubt be an exhibition Rose. Duchess of Edinburgh, Tea-scented, a pretty flower, but lacking as yet substance. Shirley Hibberd with me thin, having but, I think, eight petals. It is a beautiful bud, the colour being as described nankin yellow.—J. Hobbs, *Bristol.*

I am delighted to find that this subject has been started by so able a champion Rose-grower as Mr. Camm, and trust that the subject will be kept alive. As a rosarian of the third water, I would, with all humility, add one old Rose—namely, Camille Bernardin, which possesses a fragrance unsurpassed, and at the same time it has every other good qualification either as a garden or exhibition variety.—D. Sewell, *St. Neots, Hunts.*

Stamford Horticultural Society.—At this Society's proposed Show in September, since our notice last week, we are informed that there will be special prizes of silver cups offered

by Messrs. Sutton & Sons, Reading, for a collection of fruits; by Messrs. Carter & Co., High Holborn, for vegetables; Messrs. W. & J. Brown, Stamford, prizes for vegetables; Mr. Pearson of Chilwell for his bedding Geraniums, and Messrs. Paul and Son, Cheshunt, for twenty-four cut Roses. The Marquis and Marchioness of Exeter, the Duke of Grafton, Sir John C. D. Hay, Bart., M.P., and the Mayor of Stamford also contribute liberally to the prize fund.

HOW TO PROLONG THE SEASON OF CUTTING MELONS FROM THE SAME PLANTING.

When the Melon is grown in houses and trained to wires like Vines, planting thickly and treating them as follows will be found to have several advantages. Fewer fruit are produced on a plant, but the fruit will be better in all respects. We grow them in a span-roofed house 25 feet long by 13 feet wide, with a passage down the centre and a bed on either side, 3 feet 6 inches wide, about 14 inches deep, with a 3-inch flow and return pipe for bottom heat, and six 4-inch pipes for top heat. Although this amount of pipe gives plenty of heat, we use for the earliest planting a quantity of nice sweet hotbed material, previously prepared, put in the bottom of the bed, which raises the plants nearer to the glass and also affords nourishment to them. This is put in about ten days before planting in the form of a small ridge along the front to plant in, and sufficient to cover lightly the remainder of the bed.

When the plants are ready plant them not wider than 14 inches apart. Put a stake to each plant as the work proceeds, to support them to the first wire. When every other plant has got half-way up the house, or half the distance it is intended to train them, let this lot be stopped, which will be the means of inducing them to throw out fruit-producing laterals. The fruit on these should be impregnated as they appear. Setting is a very easy matter when Melons are grown in light airy houses: we find them to set at all times of the day, and we continue to syringe them when in bloom if the sun is bright. From the bottom wire to where we stop this lot is about 4 feet, and we generally take three fruit from each plant. The laterals are all taken off the other set of plants up as far as the others extend, but not stopping them until they get to the second wire from the top, being careful not to injure any of the leaves on the main stem. We find that we can cut fruit sooner this way, can get a more regular crop all over the house, and, we sometimes think, better fruit.

We have at present (10th of April) fruit as large as hens' eggs on those that are stopped half up the roof; while on those left to go to the top unstopped none of the fruit is set, and will not be for several days. Melons are always associated with heavy loam. Here we cannot have such without going twelve miles for it, so that it is very little we can get. The natural soil is light and sandy, but by adding large quantities of deer and cow manure we find it grows Melons well.

In choosing a male bloom let it be as large as possible and well expanded, when, if all other things are right, it will have a large amount of pollen, and be better in every way than a small one.

In cutting out the laterals let it be done with a sharp knife, so as not to injure the main stem in any way, as it is apt to canker when bruised.—A. H. T. (in *The Gardener*).

THE ROYAL HORTICULTURAL SOCIETY.

A Council meeting was held on the 7th inst., Lord Bury in the chair, and, much to his and his colleagues' surprise, the four vacancies caused by the resignation some time since of Sir A. Slade, Messrs. Chetwynd, Chambers, and Lindsay the Secretary, were filled by the election of Lord Lawrence, Mr. Grote, Admiral Hornby, and Dr. Hogg. It was believed that the four elected would serve, but we think Dr. Hogg will decline so doing. It is in contemplation, as evidence of approval on the part of the trade and amateur exhibitors, to give one of the most splendid shows ever seen in London.

How can Mr. Liggins make such an assertion as that in page 429, of the 3rd inst.? He states that "If ruin is the unfortunate fate awaiting us, the entire fault lies with the gentlemen who have left the present Council a legacy of debt beyond the power of any body of men to cope with," &c. Mr. Liggins was one of those who "turned out" the old Council, which numbered among its members some of the most experienced and successful men in London, who, with full experience of the Society's affairs, worked at its business as if it had been their own; and when they found it impossible to make the Society pay its way, negotiated with the Commissioners for an arrangement by which the Society would have been freed from rent, debenture debt, and have what was estimated to amount to £1000 in addition—that is, be some £5400 a-year better off than it now is. Mr. Liggins and his friends by strong assertions persuaded some horticulturists that the old Council had exaggerated the Society's difficulties, and that a new Council would set all to rights. We have seen the deplorable results, but I am happy to say that at last people lay the blame on the right shoulders.—George F. Wilson, *Heatherbank*.

INTERNATIONAL HORTICULTURAL EXHIBITION AT COLOGNE.

The following is an extract from a letter dated May 20th, received by the Royal Horticultural Society from the Committee managing the above Exhibition, inquiring "whether England might not, in the same manner as other foreign States, send to our Exhibition a complete collection of the produce of, and objects relating to, horticulture, to be exhibited separately, so as to give a correct picture of the advanced state of English gardening. France, as we are informed by the French Commissioner, Vicomte de Fontenay, will thus participate on a very large scale, so also Belgium and Holland, and we sincerely hope that England will follow the example set by these nations. We have, however, full confidence in our London Committee that it will do all in its power to procure a good English show."

The Royal Horticultural Society wish this communication to be generally known.

The Executive Committee have sent us the following letter, dated Cologne, May 31st:—

"Work is progressing steadily on the Exhibition grounds. The great flower and fruit hall is almost completed, and the hall for machinery will be ready in a short time. The foundations for the glass houses, eight of which have been already announced, are nearly finished. The ground has been prepared, and beds cut out for the Roses, flowers, and plants in general in the Exhibition ground adjoining the Flora. Some of the ground has been already planted, and we are happy to state that the plants are flourishing. The grass seed has been furnished by the well-known London firm of James Carter & Co.

"The Prussian Minister of Agriculture has placed at our disposal two gold and four silver medals of State. The Governments of Anhalt, Baden, and Saxon Weimar co-operate with us, and will be duly represented at the Exhibition by commissioners who have already been appointed. The Danish Government has also displayed warm interest in our undertaking, and there is every prospect of a large contribution from Denmark.

"The Government railways have agreed to a reduction of 50 per cent. on the ordinary rates of freight, as have also almost all rail and steam navigation companies. Much interest has been taken in the exhibition of fossil plants; contributions have been offered from all sides—from Government, private and public associations, and from mine-owners. Dr. Andrae, Professor in Bonn, is at the head of this department. Architecture and decorations will be represented by the most celebrated home and foreign firms. The announcements of machinery are very numerous, and the Exhibition will open to professional men as well as to amateurs many new inventions. We, in conjunction with the Minister of Agriculture, are about to select a jury for the prize distribution, and we hope soon to be able to prove to those interested that a sound choice has been made.

"The illustrated guide, together with catalogues, 50,000 copies of which will be published in due course, are in the hands of the Cologne firm of Rudolf Mosse. Foh. Bellstedt's firm in Bremen have undertaken all contracts for buildings.

"Belgium and France have arranged to exhibit each collectively, and the reports received from them are extremely favourable. We expect soon to be able to send a detailed report of the preparations made in Paris by the French Commissioners."

POROUS GARDEN POTS.

I always find my flowers grow better when the pots are kept clean washed. In many cases I have been asked by persons to tell them the reason why their plants never seemed to thrive. On examination, finding the pots dirty both inside and out, I have recommended them to wash the pots, and the result is generally satisfactory. When potting plants my custom is to wash well the inside of the pots with a scrubbing-

brush, using warm water and soap; afterwards to keep the outside clean, so as to allow of evaporation. Where the inside of the pot is not so treated the greatest difficulty is experienced in repotting, and where the outside is allowed to become dirty I have invariably found poor sickly plants. —Beta.

ALISMA PLANTAGO.

Selnom are hardy water plants vouchsafed a notice by the horticulturist, or their claims to cultivation pressed on the attention of the gardening public. Possibly it is that many of these plants are not stately in form, or gorgeous in colour, yet some of them possess both sweetness and beauty, and all are interesting from habit, or form, or properties. The plant we figure is not a brilliant plant, but it is not devoid of attraction, and it possesses a feature of interest by its medicinal and alimentary properties.

Fig. 107.—Alisma plantago.

It is commonly called the Water Plantain, and is found growing by the sides of streams in this and many other countries. It produces a long creeping rootstock, from which the leaves spring, and around which the roots are enveloped and gain support for the plant. It grows to a height of 2 feet, and bears white flowers, which are arranged in whorls or panicles.

Haller states that the plant if applied to the skin inflames and blisters, and it has been represented as poisonous if eaten by animals. Dr. Hogg in the "Vegetable Kingdom," states, that "Some years ago it was highly extolled as a remedy in hydrophobia, but after repeated experiments and a searching inquiry as to its effects, it was found to be perfectly useless." The same authority also states that the rootstocks contain starch, and when dried are eaten by the Calmucks. The plant thus appearing to lose its acridity by drying.

To those who enjoy a collection of hardy aquatic plants and wish to see the margins of streams and ponds interesting by vegetable life, this free-growing plant may be welcome. We give this information in answer to "Clericus," and in a form that may possibly be useful to others who may be interested in this somewhat neglected tribe of plants.

It is increased by root-division, or by seed sown in pots in sandy peat soil and immersed in the water. The flowers are larger than represented in the engraving, and are freely produced. The plant is of free growth, and may be left to take care of itself when once it is established.

Provincial Horticultural Exhibitions.—Immediately current are Leeds on the 9th, 10th, and 11th, and York commencing on the 16th inst. These great Yorkshire galas are usually good in extent, quality, and patronage. On the 16th inst. Burton-on-Trent and Jersey (Roses) offer liberal programmes, and on the same day the Glasgow and West of Scotland Horticultural Society holds its summer Exhibition at Glasgow.

BORDER FLOWERS—MORINAS.

One of the smallest, yet one of the most beautiful border plants we possess is Morina persica. It is said by some to be half-hardy, but I have proved it to be perfectly hardy, having had it fully exposed for at least a dozen years. I find the plants succeed in a thoroughly drained situation fully exposed, and the soil broken up to the depth of 2 feet. Good friable loam, sandy peat, well-decomposed hotbed manure, a little charcoal dust or coarse grit is a suitable compost. The border should be prepared some time before planting, to allow it to become firm. The plants should be firmly placed in the soil, and they should be well watered. They like a moderately moist, but not a wet, situation. When once well established they last a number of years.

They may be increased by division, but that sometimes proves injurious to their future well-doing, and I have known them after being wounded go off altogether. They seed pretty freely, often sow themselves where established, and may be removed at pleasure. The seed may be sown in spring, the young plants be grown on in pits or frames, and planted out in autumn or spring. They are well adapted for indoor decoration, and some should be kept in pots for that purpose as hardy herbaceous plants for exhibition. Why such plants are so seldom seen in our herbaceous borders I am at a loss to account for. Surely the time is not far distant when attention will be directed to their cultivation. We only have two kinds enumerated—I think we have room here for hybrids.

Morina persica, from Persia, is a very beautiful border plant and is the commoner of the two, but is scarcely met with in a day's journey. The flowers, being red and white, have a very pleasing effect. Morina longifolia, said to be from India, is of rather stronger habit but equally interesting, the flowers bearing a shade of purple. This species is somewhat of a rarity, and as a border flower it is seldom to be seen.—Veritas.

DIEFFENBACHIA BRASILIENSIS.

The woodcut and the following description are borrowed by us from Messrs. Veitch and Sons' catalogue of new plants introduced by them into their King's Road Nursery:—

"A very handsome plant with the well-known D. Bausei

style of growth. Its leaves average 18 inches in length by 8 to 9 inches in width. The variegation is very striking, the ground colour of the leaf being deep green, and the whole surface beautifully marked and mottled with smallish blotches of greenish yellow and white. It was awarded a first-class certificate by the Royal Horticultural Society, June 4th, 1873, and also a certificate of merit by the Royal Botanic Society, July, 1872."

By our early botanists this and other relatives would have been included in one or other of the genera Caladium or Arum. It now legitimately belongs to the genus named in honour of the German botanist M. Dieffenbach. It is one of the plants known in the West Indies as "Dumb Canes." "The Treasury of Botany" says, "The name of Dumb Cane in the West Indies is in consequence of its fleshy cane-like stems rendering speechless any person who may happen to bite them, the juice of the plant being so excessively acrid as to cause the mouth to swell, and thus to prevent articulation for several days. It is said that the West India planters were formerly in the habit of punishing their refractory slaves by cruelly forcing them to bite a piece of this plant; and accidents have occasionally occurred with it in this country, where, however, it is only to be found growing in the hothouses of the curious. The negroes in the West Indies make an ointment for rubbing dropsical swellings by boiling the juice of the plant in hog's lard; and a physician in the reign of Charles II. recommended the juice to be administered internally as a cure for dropsy, but it is so excessively acrid that it is almost impossible to swallow

Fig. 108.—Dieffenbachia brasiliensis.

it. Notwithstanding the acridity, however, a wholesome starch has been obtained from the stem. When the leaves are pulled away the stem has a cane-like appearance."

The Dieffenbachias are stove plants of considerable beauty. Their aspect when well grown is imposing, and they are a valuable addition to our fine-foliaged plants. They are admirable for exhibition purposes, and are fine for associating with Palms and Ferns. They are also adaptable for corridor decoration during the summer months. In culture they are very easy. Propagation is effected by cutting down the plants and inserting pieces of the stem in a sandy compost, and placing the pots in heat. The compost suitable for growing-on the plants is a mixture of turfy loam and peat, incorporated with sand and charcoal. When in active growth abundance of water is needed both at the roots and by the syringe. A gentle bottom heat improves the growth of the plants, and weak liquid manure improves the colour of the foliage. A high temperature, rich feeding, and copious supplies of water are the principal requirements to bring these noble plants to perfection. They are seldom injured by insects, but if affected the leaves should be washed with the sponge in preference to fumigation, which is injurious.

THE CUCKOO A CATERPILLAR-DESTROYER.

"West Surrey" (page 142), knowing no bird that will take the "filthy Gooseberry caterpillar," will be glad to hear of one, which, unlike sparrows, have no mixture of good and evil in its nature, and is welcomed alike by old and young, rich and poor. Logan draws a pathetic comparison of the joy expressed at the renewal of the well-known cuckoo note.

"Delightful visitant! with thee
I hail the time of flowers,
When heaven is filled with music sweet
Of birds among the bowers."

The cuckoo (Cuculus canorus) is a great devourer of the hairy

caterpillars, especially those of the tiger moth (Arctia caja), the stomach of the bird being lined with the hairs of the caterpillars; it has also a particular liking for the caterpillar of the magpie moth (Abraxas grossulariata), common to and committing great havoc in Gooseberry and Currant plantations. When caterpillars fail, the cuckoo has its food from the ground, frequenting newly-turned-up grass land or leys sown with a cereal crop, only too often seen looking yellow and patchy from the attack of wireworm and larvæ of the daddy-longlegs. Gilbert White mentions the cuckoo as seen by him catching the dragon flies disporting by a large pond, some of which it took whilst resting on the water plants, and others it caught on the wing.

For the past six seasons, without omitting any, I have seen the cuckoos take and clear the Gooseberry and Currant quarters of caterpillars. Shy the birds are not, for they occasionally come and remain when we are at work in adjoining quarters of the garden, but usually scrutinising their feeding-ground and adjuncts for foes before alighting from a neighbouring tree, and upon the approach of anyone flying away uttering their peculiar hawk-like cry of alarm, which is very different to their joy note.

For the last six seasons the Gooseberry and Currant bushes have been freed of caterpillars by the cuckoos. I hear of others having to water their trees overhead with a solution of white hellebore powder, 1 oz. to a gallon of water, which may be applied with a rose watering pot or by a whitewash brush sprinkled over the parts infested by caterpillars; this is rendered quite unnecessary here by the aid of the cuckoo. The Apple and Pear trees have the leaves eaten through and through by caterpillars, and the destructive "worm i' the bud" spoils the hopes of the rosarian. It is a gratifying and instructive sight to see the sparrow—house sparrow (Passer domesticus) passing from tree to tree, and from those to its nest, carrying in its beak the food which its young receive with joyous clamour. In this garden is a Scotch Fir prized for its age, hence it is privileged to appear so prominently within walls, and this tree is a favourite nesting place of the sparrow, and is at all seasons a favourite resort of these and other birds. It is to them no doubt a halting place, one that commands the surrounding ground, and is therefore advantageous as a "look-out." Chaffinches watch us from it sowing seeds; it is no use, the seeds are never sown without first being coated with red lead. Linnets use it, the blackbird and thrush giving their clarion notes perched on the pollard arms, which ring out sweetly on the still clear air. Hedged-in shrubberies, into which at dusk may be seen flocks of linnets, chaffinches, and sparrows descending, backed by plantations all around, and abutting a wood which extends east to west six miles in a valley with a rivulet meandering through mud or running through over rock; the whole spot is an aviary of native and migratory birds. A dabchick or little grebe (Podiceps minor) was caught last November in one of our stokeholes, which along with the preceding are given in evidence of the verdict not being arrived at through a paucity of material.

Of cuckoos I have seen six together. This year they seem scarce; I have not seen more than one, and only heard two. Doing no harm the cuckoo has no foe in man, but its approach is marked by some of like feather with marks of great disapprobation. If, as alleged, the cuckoo be a sucker of birds' eggs, there can be some excuse for the great clamour raised by the smaller birds upon the intrusion of one in, over, or near the nesting domain. This is not, however, any proof that the birds have instinctive knowledge of the cuckoo as a destroyer of their eggs, for they are equally ready with a cry and chase after the night-jar (which does not suck goats any more than hedgehogs do cows), or any bird in the shape of a hawk, driving the birds so tormented to seek refuge in flight. The missel thrush and blackbird are notoriously clamorous over the intrusion of a cuckoo to the nesting places. Equally uncertain is the finding of empty shells in bird-nests of the cuckoo being the content-takers. The jay and magpie are well known destroyers of eggs, but proof is wanting of the cuckoo being at all connected therewith.—G. Abbey.

The Preservation of Flowers.—A vessel with a moveable cover is provided, and having removed the cover from it a piece of metallic gauze of moderate fineness is fixed over it and the cover replaced. A quantity of sand is then taken, sufficient to fill the vessel, and passed through a sieve into an iron pot, where it is heated, with the addition of a small quantity of stearine, carefully stirred, so as to thoroughly mix the ingredients. The quantity of stearine to be added is at the rate of half a pound to 100 lbs. of sand. Care should be taken not to add too much, as it would sink to the bottom and injure the flowers. The vessel, with its cover on and the gauze beneath it, is then turned upside down, and the bottom being removed, the flowers to be operated upon are carefully placed on the gauze and the sand gently poured in so as to cover the flowers entirely, the leaves being thus prevented from touching each other. The vessel, is then put in a hot place—such, for instance, as the top of a baker's oven—where it is left for forty-eight hours. The flowers thus become dried, and they retain their natural colours. The vessel still remaining bottom upwards, the lid is taken off, and the sand runs away through the gauze, leaving the flowers uninjured.—(*Pharmaceutical Journal.*)

VARIATIONS AND NAMES OF COLOURS.

The various colours which now distinguish the foliage of different plants constitute some of the most striking phenomena of the vegetable world. Great is the variety of tints, which are peculiarly interesting, and are worthy the attention of every observer of nature. There is a wide field for investigation. Some think it a disease, but I think those bright and beautiful colours blended together as some are cannot be disease. The different colours of leaves and flowers, and the names to which those differences have given rise, are so many that the subject is one that deserves to be treated as a separate branch of science. This variety of colouring appears to me jointly to depend on the various structures of the leaf and on the different chemical actions to which those leaves are subject, some of them evidently depending on soil and situation, or from excess of heat or cold and causes hitherto unascertained.

Although this change in the colour of the leaves cannot as yet be explained, yet we know some of the laws that influence the colour of flowers. Blue flowers will turn to white or red, but never to yellow. A bright yellow flower will sometimes become white, but is never known to become blue. From whatever circumstances a leaf is subjected to change in colour there is one fact certain—it in most cases adds greatly to their beauty, and desirable acquisition for ornamental purposes. The different hues assumed in course of development, the bright

colouring appearing in many tints, forms, and shades, always contrasting with the natural green.

No variation of plants is more common than those of colour, and the colour of plants is one of the readiest marks of distinction. We find it scattered through all the classes of nature animate and inanimate, decking with tints of equal brilliance the shell, the gem, birds, beasts, and reptiles, clouds which attend upon the rising or setting sun, as well as our leaves and flowers, and with no apparent use but that of delighting and cheering mankind with a perpetual display of beauty.

This beautiful provision of nature has a power of imparting a charm to things the most trivial and otherwise unattractive, but there is nothing that strikes us so agreeably at first sight as the colour of flowers; it excites our admiration, and we are attracted by its loveliness and charmed with its beauty. The following are the principal colours, and the terms used to distinguish them:—When the margin of the leaf is yellow it is called folia aurea; when the centre has a yellow spot it is folia aurea variegata; when the leaf is white on the margin it is called folia argentea, or albo-marginata; when it is white in the centre it is called folia alba or argentea variegata; if the leaf is striped or streaked it is known as striata; if a leaf has two colours it is called bicolor; if three colours it is called tricolor; if the colours are various it is called versicolor; if spotted, maculata. Again, the leaves of some plants are blackish, when this is the case it is called nigricans; when quite black, ater; black with a tinge of grey, niger; copper-coloured, cuprea; very dark red approaching to black, atro-purpurea; reddish, rubescens; red-stalked, rubicaule. When the leaf is shining, like the Holly for instance, it is called nitida; velvety as seen in the Coleus and the Gesnereæ, it is called velutina. All those plants whose leaves appertain to black contrast well with colours appertaining to yellow or orange, also to silver-grey. As the surface colour of the foliage of different plants is very various terms have been used to describe them.

Again, some plants appear as if covered with a kind of white dust or powder, as the Auricula and the beautiful Echeveria pulverulenta, and E. farinosa; lucanus a silvery-white-looking substance covering the leaf, as the well-known Veronica incana and Santolina incana; Tomentose or Cottony, a white cotton-like substance covering the whole leaf.—Nathan Cole, *Kensington Palace Gardens.*

PLANTS FOR A GRAVE.

Observing in the Journal of 20th of May last a request for information on this subject, I offer a few remarks—results of a practical experience of the difficulties attending any permanent decoration of graves—difficulties so great, in fact, that I have no hesitation in recommending the total abandonment of the idea, unless exceptional advantages in individual cases may render the chances of success somewhat probable.

Most of the metropolitan cemeteries are established on a heavy clay soil, which in the winter is excessively damp if not actually waterlogged, and in the summer, should a few weeks of fine weather occur, the soil becomes parched and cracked. To such an extent does the latter condition often attain, that I have seen gaps of several inches in width between the earth and the coping of the grave, leaving the roots of the plants exposed to the drying influence of the sun, and causing their destruction or deterioration for the season. Another obstacle to any permanent decoration is the rapid growth of weeds, which will in the course of a few weeks entirely smother, and eventually starve out, the cultivated plants.

In such places the remedy is to have the staple soil entirely removed to the depth of 1 foot or more, and the space filled to overflowing (so as to allow for settling) with a compost of light loam and leaf mould, sharpened with grit or silver sand. In the case of an ordinary middle-class grave, say 6 feet by 1½ foot, with head, foot, and curb stones, the gardener attached to the cemetery will do this part of the business for a few shillings, and we may then proceed to plant many subjects with fair hopes of success.

The plants employed in such a limited space should be of dwarf and slow growth, or their appearance will in a short time be unsatisfactory. An example will, perhaps, be more generally useful than a selection of plants however carefully prepared. A very suitable effect may be produced thus, supposing we commence in the autumn:—Centre, a variegated Euonymus sunk in its pot, with a thumb pot inverted underneath for drainage. At each end a two-year-old plant of Iberis corifolia: this is evergreen, and makes a fine show of pure white flowers in May. Down each side next the coping a row of Sempervivum californicum, of which offsets struck now will make nice plants by September, and two dozen will suffice. At each corner plant half a dozen mixed Crocuses about 5 inches deep, and above the Crocuses the same quantity of Snowdrops (single) 3 inches deep. There will be space left for a few small plants of Golden Thyme, or a groundwork of gold-tipped Stonecrop (Sedum acre aurea).

This arrangement will look well until quite the end of May, when the Thyme and Stonecrop begin to turn green and may be taken up. The Iberis should have its flower stems removed and be slightly pruned-in, the leaves of the Crocuses, &c., will have died off, the Euonymus can be lifted, the ground levelled, and a fresh combination attempted. In the centre a plain cross formed of Golden Feather Pyrethrum (two rows of smallish seedlings are better than one of larger plants), and the intermediate space filled-in with Lobelia pumila planted very closely together will look well; or the cross may be of Echeveria secunda glauca raised a little, and the groundwork of Golden Feather sunk an inch or two. If the cross should be considered too "high," the same plants may be arranged as a ribbon parallel with the Sempervivums. Alternantheras and most of the dwarf succulents may be turned to good account in this style of planting. A small grave may thus be kept appropriately decorated with only two changes in the year; but if frequent visits can be made to it, the Golden Feather Pyrethrum will look all the better in the autumn for an occasional severe pinching-back to keep it down and prevent it flowering. The edges of the plants should also be cut into a tolerably even outline, and not be allowed to straggle and mix.

A larger or family grave may be planted with fuller-sized plants, and there being a greater body of soil, the extremes of heat and cold will not so much affect the plants as in the case of a small grave. Dwarf Conifers or evergreens, bulbs of all kinds, monthly Roses, and fine-foliage plants are admissible, and will do pretty well if properly attended to; but the most satisfactory plan would be to have the top spit of soil removed entirely, and the space filled with cocoa-fibre refuse in which to plunge the plants in their pots. Any amount of variety and any number of changes can then be made, and bulbs, such as Tulips, Hyacinths, and Polyanthus Narcissus, may be bloomed one season in the fibre without any pots, saving much trouble. The brown fibre brings out pleasingly the colours of the leaves and flowers, and is uniformly moist under the surface in the hottest weather. Almost any plant that can be grown and flowered in a pot will be available, and I know such a grave, which always looks bright and beautiful. It is in Nunhead Cemetery behind the chief chapel, and can be easily found.

In conclusion, I object to the decoration of graves with gaudy flowers, such as scarlet Geraniums and yellow Calceolarias (because in all well-kept cemeteries the principal walks are bordered with beds of such flowers), especially in the more retired parts of the grounds, where repose and quiet beauty should reign supreme, in harmony with thoughts of those whom we hope to join when we shall have planted our last flower, and gone to rest from our labour in "God's acre."—F. B., *Blackheath.*

ROYAL NATIONAL TULIP SOCIETY'S SHOW.

The above was held in the Botanical Gardens, Manchester, on May 29th, and the Show was remarkable for the high quality and condition of the flowers exhibited. Cheshire, Lancashire, and Yorkshire were strongly represented; and there were also growers present from Nottinghamshire, Derbyshire, and Warwickshire.

Tulips further south were over, and indeed several fine collections in the midlands were over also, or past their strength. The collection of our Hon. Sec., my friend Mr. Barlow, which I am not afraid to say is the richest and most select in the country, was unfortunately crippled this year by some extensive and dangerous injury to the bulbs at rooting time. The young fibres had, in countless instances, mysteriously refused to face the new soil. A slight layer from a hedgeside had been laid on for the bulbs to start in, and all, when once through this, did well. The diagnosis is difficult as to whether the affection is a sudden disease in a collection of long standing health grown by a safe old hand, or due to some unsuspected harm in that inch of innocent-looking soil.

Seeing that this is about the first time that affairs of the florist Tulip have been brought forward in the Journal, and many readers might be puzzled by technicalities in the prize

list, yet interested to know a little about the classification, points, and peculiarities of this most famous flower, I will briefly explain that our Tulip, which is a taller and later variety than any of the toy sorts so prettily played with in the garden game of bedding, has been classed by florists in three main divisions.

One class is termed Bizarres. These have yellow ground colours, and the marking is laid-on in black or red, and in many varying depths of brown. Another class goes by the name of Roses. Flowers in this have a pure white ground colour marked with rose, red, or scarlet. The third division consists also of white-ground flowers, but the marking here is in some shade of purple, from lilac to almost black: these are termed Byblœmens.

Each of these three classes is subdivided into two most important sections, depending upon the two recognised arrangements of the marking upon the ground colour. Either it is laid in beautiful styles of pencilling round the edge only of the petals, or else this pencilling is joined by bold beams of colour that rise like fireflashes up the petal-centre, and strike into the pencilling of the edge with their sharp tongues. A flower pencilled only is called a Feathered flower, and one that is beamed and pencilled is called a Flamed flower. The feathering must not break off anywhere round a petal edge, nor the flame be undecided, scratchy, or insufficient to strike to the feather.

The base of the flower must be pure yellow or white, as the case may be; and the stamens, upon which six bold black anthers stand, must be pure as the ground colour. Each flower is perfect at six petals and cannot be exhibited with more, though there are often blooms with seven or eight, and the shape is thus spoiled. Petals are to be broad, smooth on the edge, level on the top, and of fine polished surface and substance, so bending upwards from the base as to first form a good shoulder. The precise proportion for the cup of the flower has been a sorely vexed question. The practical solution is that we grow some rather long-cupped flowers, such as Queen of the North and Kate Connor, and also short-cupped flowers like Orion and Dr. Hardy, which last are of fine propertion in this respect.

In Tulips raised from seed a most curious fact is noticed: The young seedlings which may begin to bloom the fourth year after sowing, but more generally the fifth and sixth, will, with very rare exceptions all bloom self-coloured. At this stage they are selected for substance, shape, and purity, colour just now being of small moment, as only temporary. In this self-coloured state they are called Breeders, and season after season as they are grown now one and now another will "rectify," or "break" as it is termed, into feathered or flamed flowers, or some attempt at either. The classes they will belong to is a point decided by the base colour of the breeder, or by colour of base and petal considered together. If the base be yellow the flower is a bizarre, if white a rose, or byblœmen. Roses break from a white base, and pink, red, or scarlet body colours. Byblœmens form a white base and body of lilac, violet or purple. A seedling with lilac body and yellow base is worthless, for it will break into an inadmissible flower called a tricolor. It will have two ground colours—white and yellow, deriving its white through the byblœmen lilac of the breeder, and its yellow through its base as a bizarre. A red body and yellow base may be kept for the chance of a red bizarre, but as a rule, like the ugly duckling of the story, the young swan, the plainer and weaker colours in the breeder flowers generally produce the richest in the rectified state.

It is additionally strange that the breeder or mother colour is not simply driven or collected into beautiful markings on the rectified petals, but that it disappears from the flower altogether, as a mist or veil lifted off. The base colour floods the whole flower with its pure white or yellow, and a new and marvellous colour strikes in to feather or flame the petals. A few bloom "rectified" from the first, and are then said to have had no breeder. The separate bulbs of any one good seedling will some of them break feathered and some flamed, and others in neither one clear character nor another. Each bulb when broken transmits its own character to its every offset. This is the origin of "strains" in Tulips, for as each bulb leaves the breeder state it becomes the founder of a strain good or bad. Hence there is much in a strain as in a name in Tulips.

The breeders are a very lovely class of flowers. Among the roses especially there are the softest and most beautiful pinks and reds. There is nothing gaudy, rough or rude about the florist Tulips; and though we like to break the breeders out, we value them very much in their light unfigured morning dress. When they will break and how to break them no one knows, or probably ever will know. Many coaxings and hardships have been tried upon them, and many an eccentric experiment made. Change of soil and locality seem to do something—perhaps more than anything—towards breaking breeders, but all seems mystery, and every result past anticipating. This all makes the work wonderfully speculative and interesting; and when it is seen how long is required to bloom a Tulip from seed, and have it rectified from the breeder in a good strain, the prices that have been paid for Tulips will seem less excessive.

Nearly all that compete at our National Show and elsewhere are English-bred seedlings. We have left the Dutch varieties far behind, and the appearance of fine new rectified seedlings at the National has now become a most marked and interesting feature of the show. Many of us are raisers; and our worthy President, Dr. Hardy, now rests upon his Tulip laurels with the honour of having raised, in his Talisman and Ajax, two champion flowers in their classes.

It will, of conrse, be seen that the rectifying of good new seedlings is the way to improved and distinct varieties. When a breeder rectifies it always adopts a shorter stature and more refined habit. Some varieties diminish very much in height when their breeders break. The foliage of the breeders is a rich dark green with a fine blue bloom on it in which you might write your name. It is less vigorous when the bulb rectifies and shows, long before the bud colours, a mottling and streaking with lighter green—the habit of rectified Tulips, and a certain sign beforehand that breeders are broken.

For rectified seedlings special certificates of honour are awarded at the National, and several obtained the distinction this year. Among them—J. Forman, fea. byb.; Duke of Edinburgh, fea. biz.; Mrs. Cooper, a lovely fea. rose; Mrs. Plackitt, fea. byb.; Mr. Barlow's Little Annie, not open on the cold day of the Show, is a gem of the first water.

In the older and established new sorts the following were shown in grand character:—

Flamed Bizarres.—Dr. Hardy, Sir. J. Paxton, and Ajax.

Feathered Bizarres.—Demosthenes, Commander, Masterpiece, Duke of Edinburgh, Paxton, and Sovereign.

Flamed Roses.—Triumph Royal, M. St. Arnaud, Annie M'Gregor, Aglaia, Kate Connor, and Mabel.

Feathered Roses.—Heroine, Aglaia, Industry, Modesty, Mrs. Lomax, Charmer.

Flamed Byblœmens.—Talisman, and Duchess of Sutherland.

Feathered Byblœmens.—Bessie, Mrs. Cooper, Adonis, J. Forman, Mrs. Plackett, and Violet Aimable.—F. D. Horner, *Kirkby Malzeard, Ripon.*

Class 1.—*For four stands of twelve dissimilar Tulips*, two feathered and two flamed in each class.—1, Silver cup, W. Whittaker, with Talisman, Mabel, Lord Byron, Masterpiece, Paxton, Madame St. Arnaud, Duchess of Sutherland, Seedling, Violet Amiable, Industry, Bessy, and Dr. Hardy. 2, Rev. F. D. Horner, with Mrs. Cooper, Triumph Royal, Talisman, Bessie, Modesty, Demosthenes, Dr. Hardy, Kate Connor, Ajax, Adonis, Commander, and Heroine. 3, T. Mellor, with Heroine, Ajax, Aglaia, Paxton, Adonis, St. Arnaud, Sulphur, Charles X., Chancellor, Violet Amiable, Duchess of Sutherland, and Mabel. 4, J. Hague, with Mabel, Queen of May, Heroine, Orleans, Triumph Royal, Dr. Hardy, Ratcliffe, Paxton, Adonis, Dreadnought, and Ajax.

Class 2.—*Seven stands of six dissimilar Tulips*, one feathered and one flamed in each class.—1, W. Whittaker, with Bessy, Talisman, Sir Joseph Paxton, Masterpiece, Nanny Gibson, and Sarah Headly. 2, T. Haynes, with Duke of Edinburgh Heroine, Talisman, Triumph Royal, Mrs. Pickerill, and Sir Joseph Paxton. 3, Rev. F. D. Horner, with Annie M'Gregor, Bessie, Paxton, Commander, Talisman, and Modesty. 4, S. Barlow, with Annie M'Gregor, Bessie, Demosthenes, Paxton, Talisman, and Heroine. 5, — Forman, with Triumph Royal, Emma Brookes, Jemima Forman, Duchess of Sutherland, Merit, and Masterpiece. 6, W. Lea, with Adonis, Duchess of Sutherland, Triumph, Heroine, Dr. Hardy, and Masterpiece. 7, D. Barber, with Mary Barber, Sarah Headly, Paxton Feathered, Paxton, Talisman, and Mrs. Pickerill.

Class 3.—*Four stands of six dissimilar Tulips*, one feathered and one flamed in each class.—1, H. Housley, Stockport, with Sir Joseph Paxton, Mabel, Talisman, Unnamed, Aglaia, and Amiable. 2, W. Lea, jun., with Madame Arnaud, Heroine, Duchess of Sutherland, Adonis, Dr. Hardy, and Demosthenes. 3, S. Smedley, with Heroina, Triumph Royal, Sovereign, Talisman, Dr. Hardy, and Mrs. Pickerill. 4, S. Woolley, with Aylotte, Anastasia, Adonis, Dr. Hardy, and Catafalque.

Class 4.—*For six stands of three feathered Tulips*, one of each class.—1, T. Mellor, with Lord Lilford, Angelina, and Rachel. 2, Rev. F. D. Horner, with Friar Tuck, and Heroine, and J. Sanderson. 3, W. Lea, jun., with Heroine, Demosthenes, and Queen of the North. 4, C. Forman, with Sovereign, Heroine, and Jemima Forman. 5, T. Hague, with Duke of Edinburgh, Mrs. Pickerill, and Duke of Edinburgh. 6, W. Bentley, with Adonis, Madam St. Arnaud, and Masterpiece.

Class 5.—*For six stands of three flamed Tulips*, one of each class.—1, T. Hague, with Dr. Hardy, Duchess of Sutherland, and Triumph Royal. 2, W. Whittaker, with Paxton, David Orleans, and Angelina. 3, W. Lea, with Seedling, Dr. Hardy, and Triumph Royal. 4, T. Mellor, with Mabel, Chancellor, and Storer. 5, Rev. F. D. Horner, with Triumph Royal, Duchess of Sutherland, and Ajax. 6, W. Wiseman, with Dr. Hardy, Duchess of Sutherland, and Henrietta.

Class 7.—*Six stands of two Tulips*, one feathered and one flamed of any class.—1, W. Whittaker, with Masterpiece and Dr. Hardy. 2, C. Forman, with Mary Plackitt and Sir John Franklin. 3, T. Mellor, with Sulphur and Lord Denthsm. 4, J. Turner, Stockport, with Heroine and Paxton. 5, H. Housley, with Sovereign and Paxton. 6, C. Barnes, Birmingham, with Sarah Headly and Dr. Hardy.

Class 8.—*Single Blooms.—Feathered Bizarres.*—1, W. Lea, Masterpiece. 2, 5, and 8, W. Whittaker, Richard Yates, Sulphur, and Royal Sovereign. 3, 4, 9, and 10, Rev. F. D. Horner, J. Sanderson, Demosthenes, Seedling, Tiny Tim, and Garibaldi. 6, J. Hague, John Ratcliffe. 7, G. Pickerill, Sir J. Paxton. *Flamed Bizarres.*—1 and 4, T. Haynes, Sir J. Paxton and Lord Stanley. 2 and 3, W. Lea, Dr. Hardy and Seedling. 5 and 6, W. Whittaker, Seedling and Prince of Wales. 7, J. Turner, Ajax. 8, D. Barber, Ganymede. 9, J. Atkin, Sulphur. 10, Rev. F. D. Horner, Seedling. *Feathered Byblœmens.*—1 and 6, W. Lea, jun., Adonis and Seedling. 2, 4, and 8, W. Whittaker, Mrs. Pickerill, Violet Amiable, and Magpie. 3, J. Morris, Queen of the North. 5, J. Turner, Talisman. 7, S. Smedley, Firstrate. 9, — Barlow, Seedling. 10, D. Barber, Adonis. *Flamed Byblœmens.*—1, 10, — Barlow, Nimbus, and Seedling. 2, — Wiseman, Duchess of Sutherland. 3, D. Barber, Talisman. 4, 6, and 7, W. Whittaker, Bacchus, Lord Denman, and Alexander Magnus. 5 and 8, T. Mellor Thalia and Adonis. 9, — Haines, Queen of the May. *Feathered Roses.*—1, 2, 4, 7, Rev. F. D. Horner, Heroine, Modesty, Mrs. Lo-

max, and Aglaia. 3, 5, and 6, W. Whittaker, Sister to Rachel, Nancy Gibson, and Lady Wilton. 8, H. Houseley, Mrs. Lea. 9, J. Hepworth, Miss Collins. 10, D. Barber, Charmer. *Flamed Roses.*—1, H. Housley, Aglaia. 2, 3, 6, 7, and 10, T. Mellor, Mabel, Lady Catherine Gordon, Ada, Mrs. Talfourd, and Madame St. Arnaud. 4, W. Lea, Lady Olivia Sparrow. 5, W. Lea, jun., Mrs. Ashton. 8, J. Hepworth, Improved Triumph Royal. 9, Whittaker, Queen of England.

Premier—The best feathered Tulip in the whole Exhibition.—W. Whittaker, with Hepworth's Bessie. Premier.—The best flamed Tulip in the whole Exhibition.—H. Houseley, with Millison's Sir Joseph Paxton.

BREEDERS.

Class 10.—*For four stands of six dissimilar Tulips*, two of each class.—1, T. Mellor, with Lady Grosvenor, Alice Grey, Annie M'Gregor, Sir Joseph Paxton, and Norval. 2, W. Whittaker, with Ariosto, Talisman, Richard Yates, and Annie M'Gregor. 3, W. Lea, with Seedling Queen of England, Duchess of Sutherland, Seedling, Dr. Hardy, and Paxton. 4, Rev. F. D. Horner, with Talisman, Seedling, Hepworth Seedling, Lady Grosvenor, Richard Yates, and Hardy's Seedling.

Class 11.—*Six stands of three Tulips*, one of each class.—1, T. Mellor, with Annie M'Gregor, Ariosto, and Norval. 2, W. Lea, jun., with Duchess of Sutherland, Juliet, and Dr. Hardy. 3, D. Woolley, with Mabel, Delicata, and Ariosto. 4, W. Lea, with Seedling, Queen of England, and Richard Yates. 5, W. Whittaker, with Queen of England, Dauntless and Dr. Hardy. 6, Rev. F. D. Horner, with Hardy's Seedling, Dr. Dalton, and Unknown.

Class 12.—*Bizarre Breeders.*—1 and 6, T. Mellor, with Atlantic and Sulphur. 2, 4, and 5, W. Whittaker, with Paxton, Dr. Hardy, and William Wilson. 3, W. Lea, with Richard Yates. *Rose Breeder.*—1, 3, 6, T. Mellor, with Annie M'Gregor, Queen of England, and Mabel. 2, W. Whittaker, with Juliet. 4, S. Barlow, with Hepworth Seedling. 5, W. Lea, with Seedling. *Byblœmen Breeder.*—1, 3, 5, 6, T. Mellor, with Northern Light, Bridesmaid, Chancellor, and Wm. Bentley. 2, S. Barlow, with Seedling. 4, T. Richardson, with Unknown.

Class 13.—For the best breeder Tulip in the whole Exhibition, in addition to any other prizes it may have won.—T. Mellor, with Paxton.

STRAWBERRY PROTECTION.

An unusual show of blossom and an unwonted immunity from spring frosts lead us to hope for heavy crops of fruit this season. Than Strawberries few crops of the garden are anticipated with greater pleasure, and also, it must be added, with greater anxiety. The cool, refreshing, delicious fruit is ever welcome on the dessert and breakfast table, and the ripening of the outdoor crops is always longed for; but with this longing is mixed the fear lest dirt should injure, and slugs and birds eat, the best-flavoured and most handsome specimens. To best preserve the fruit and carry it to perfection is now one of the duties pertaining to all who are responsible for the full and satisfactory supply of this important crop, and a notice of the means usually employed at this period of the year to preserve and protect the fruit will not be inopportune.

As to preserving the fruit from dirt and grit various means are adopted, and it is not so much a question as to which mode is the best, as which is the most convenient for the adoption of each particular individual and the most suitable to his circumstances. Generally speaking the practice of surfacing the ground with manure in the autumn not only answers the purpose of protection from frost, and by the washings of the rains conveys nourishment to the soil; but this washing and bleaching also leaves a close, clean, strawy surface in the spring for the fruit to rest on, and from which it can be gathered in a clean sweet state. Than that plan few are simpler and better when carried out properly and under circumstances to which it is suited; but the plan is not always suitable. In wet soils the manure is liable to cause a decay of the crowns, and in gardens where slugs are unusually numerous the winter's surfacing affords them harbour, and they emerge from their haunts in the spring and destroy the fruit. However, where the practice has been adopted but little more is now needed on the matter of cleanliness, but where it has not been adopted measures must be taken forthwith, or a thunder shower of half an hour's duration may spoil the work of a season's preparation.

Whatever means are adopted for keeping the fruit clean, it is important that the material be applied at once. To defer the surfacing of the ground until the fruit is approaching ripeness is an error which is too often committed. The heavy fruit cannot be lifted to have straw put under without injuring the stems, the result of which is a check to the swelling of the fruit. The rough handling of the trusses is a prime source of small fruit, as the stems are as susceptible of injury as is the haulm of Peas. Protection should be given when the stems are erect, and before they are flattened to the ground by the weight of the fruit.

Mr. Douglas uses twiggy sprays to sustain the fruit above the foliage. The plan is a good one, but all have not the twigs, and a capital substitute is to stick three or four sticks round each plant, and run a strand of twine round each root, or if the roots are close, a strand along each side of the rows will suffice. That plan is simple and effectual. Bricks, tiles, or slates under the plants are also good for the purpose of cleanliness. Some have wire supports, which is simply a half-circle of wire on three legs. These are stuck in the ground—two half-circles to each plant—and form a capital supporting cradle. These are easily made, and will last for years. Short grass is used, but it fills the ground with weeds, and is dashed into the fruit by rains, and cannot be recommended. Tan is permissible, but better is fine shavings or trimmings from the basketmakers. Spent hops answer very well, and are successfully used in brewers' gardens.

We now come to straw, which is always effectual. The best way to use it, however, is in a cut state. If cut in inch lengths it is easily put round the plants from baskets; half the straw will do, and it is more quickly applied than when in an uncut state. It is, moreover, the best preservative of the fruit from slugs. The round loose particles are to them no sure foundation, and they cannot travel freely on the ever-moving surface. This useful plan was, I think, first suggested by Mr. Peach. Mr. Wright has also proved its worth, and stated its merits some time ago in the Journal. I can sustain both those cultivators in recommending it, having tested it against almost all other modes, and for quick and easy application, keeping the fruit clean, and baffling the slugs, I think it the best of all applications. The plants in the north are just going out of bloom, which is the very best time to surface the ground; but by all means let it be done before the fruit is half swelled off. Any of the above means will keep the fruit clean, and each can select the material which is most convenient to his own particular case.

And now as to protecting it from birds. Guns and scarecrows are of very little use, as the birds will in a few days make perches of them. The gun is the best deterrent—when it is there, but the birds are quick in detecting its absence. A quaint old cultivator procures cat's skins and stuffs them, and these dummies skulked about in the beds, changing their positions every day, is about as old-fashioned plan as any, and, although it may provoke a smile, it is one of the very best to keep the birds at a distance. A tethered hawk is also a capital Strawberry guardian.

But the general plan is to net out the birds. Herring net is cheap, and should be freely supplied to all fruit gardens, especially where ground is limited and every pound weight of fruit is an object. The common plan is to lay the nets over the plants, and remove them when the fruit is gathered; that plan will answer, but it is clumsy in comparison with spreading the nets over the beds at 5 feet from the ground. Stakes driven in at convenient distances, and roof laths tacked from stake to stake, is a framework which is quickly made, and over which the nets can be spread and pegged to the ground all round the bed. It is only to draw aside the net to gain admittance, and the fruit can be gathered in comfort. There is time saved in covering and uncovering, and the net is much less liable to rot than if laid on the plants. The framework plan of netting is, in the end, economical, and it is also comfortable and effectual. Gooseberry and Raspberry quarters can also be netted-in in the same way, and fruit, trouble, and labour will be saved, but for Strawberries especially it is the neatest, cheapest, and the best of all modes of fruit protection; at least, so far as is known to—A Northern Gardener.

CUT-BACK ROSES.

The question which Mr. Camm has raised as to whether the best blooms come from the maiden plants or those which have been cut back, is one which I am sure will greatly interest all Rose-growers, and will, I expect, provoke some amount of discussion and elicit many different opinions.

Having grown scarcely anything but cut-back Rose bushes for many years, during which as an exhibitor I think I may lay claim to a fair amount of success, I certainly must say that in my opinion the blooms from them both in form and quality far surpass maiden blooms, as there is an entire absence of that coarseness so often found in the latter, but at the same time there are some weighty arguments on the other side.

Cut-back bushes are much more liable to injury from late spring frosts, and they also require more care and trouble in their cultivation than maiden plants; the latter, if the ground is properly prepared before the stocks are planted, require very little attention except as regards keeping them free from fly, and of course the usual tying and disbudding; but if you want

fine blooms from cut-back plants you must not forget to treat them liberally with some of that "mock turtle" which Mr. Reynolds Hole so well says "never fails to act as quinine and Guinness to the weakly, and a generous wine to the strong."

Another and a very great objection, more particularly to an exhibitor, is that Manetti plants—and I speak more particularly of them—must be pruned early. The stock is so excitable that if you prune late they bleed, and in most instances die back; the consequence is, that with a forcing season like the present your bloom comes too early for many of the principal shows, as I almost fear will be my case this year, notwithstanding my good friend Mr. Camm's kind prophecies on my behalf. Now with maiden plants I should pinch back one-half of them as soon as they have fairly started into growth, and thus ensure a continuance of fine bloom for a much longer period.

My answer to Mr. Camm's question, then, is this, that in form and quality cut-back blooms are most decidedly superior to those from maiden plants, and this I say not forgetting that the very best box of blooms I ever saw in my life was a box of Horace Vernet shown by Mr. Cranston at Hereford in 1873, and they were all maiden blooms—they were simply superb. But my advice to Rose-growers, and more particularly to exhibitors, is that they should do as I hope to do for the future. Grow some of each; grow your plants one year as maidens, the following year cut them back and then have done with them By dividing your Rose ground into three divisions this can very well be done, as there will be one portion for the stocks, Manetti or Briar whichever is preferred—and I strongly advocate the former—another for the maiden plants, and another for cut-back plants, and if this plan is carried out I am sure the exhibitor will have a succession of bloom which will last him from the earliest show until the latest.

I cannot conclude these remarks without saying a word in praise of that glorious Rose Cheshnut Hybrid, which was raised by Mr. George Paul. Of it being a pure Tea Rose I have grave doubts, but I could stage twenty-four blooms of it now which I am sure, for form, colour, and substance would hold their own against any other Rose that I know. I would strongly recommend all growers who have no plants of it to procure some and plant them against a south wall, and they will have something of beauty which will be to them "a joy for ever."—Robert N. G. Baker, *Heavitree.*

NOTES on VILLA and SUBURBAN GARDENING.

The Primula, Cineraria, and Calceolaria.—Perhaps there are no more suitable plants to call an amateur's attention to than the above, for with these three beautiful plants fairly grown he may secure to himself a goodly share of bloom from Christmas up to the middle of June, and neither are these plants of that nature that will call into request an amount of skill beyond the amateur's attainments; the treatment they require is plain and simple, and it is certain they will pay for the pains taken with them.

Primulas.—Of these there are several strains of more or less variation in colour, and some of a semi-double character, which no doubt are more lasting when cut than some others, but I confess to having a liking for the old Fimbriata rubra and alba, red and white, or such as market gardeners bring into Covent Garden at Christmas time and onwards. These are such as the amateur will not be disappointed with. Seed can be purchased mixed or the colours separate, which is perhaps the best way to buy for a more perfect strain. For blooming at Christmas the seed should be sown without delay, and those who already have their plants up will perhaps have a slight advantage; nevertheless, sow at once in a pan or pot of well-drained soil, say sandy peat run through a fine sieve, cover the seed very lightly, press the soil slightly over the surface, water it at once, and place a thin layer of moss over it to prevent the sun from drying the surface too fast; place the pots in a frame where Cucumbers or other plants in a similar temperature are growing. By no means allow the soil to become dry, especially after the seed has commenced germinating. When the seedlings have attained a couple of seed leaves large enough to handle properly take them up by the root carefully with a pointed stick, and prick them an inch apart in pots filled with a similar soil; keep them in the same temperature until they have made at least three leaves, with one or two others showing, then they will be fit to pot off separately into small pots, adding this time with the peat a little turfy loam, and let them be mixed well together.

In potting take care that the plant is placed just low enough to be held in its place by the soil to prevent the plant falling about. This time the plants may be placed in a small frame, on a bed of ashes if possible, and near to the glass. When the plants show themselves established give them more air, but still an intermediate temperature, with occasional sprinklings of water over the foliage in the evenings of hot days. As the plants grow on a slight shade will be necessary, and as the pots become full of roots give other shifts till they occupy the sized pot required, which is generally a 6-inch pot. When the plants become strong the soil may consist of mostly turfy loam and sand, with about a quart of dried cow manure finely sifted to each two gallons of earth. Should the loam be of a heavy nature a little leaf soil mixed with it will be better than peat to lighten it, but if not heavy do without the peat. Such soil will grow them well. After the plants have had their last shift the frame should be placed upon bricks, so as to admit air beneath as well as above them; this greatly strengthens them, and induces the leaves and leafstalks to become short and sturdy. Do not let the plants remain too long in a dry hot atmosphere without sprinkling the soil around the pots, and when the weather is warm and the plants strong allow them to have air night and day, little or much according as they may be going on. Turning now to the

Cinerarias, I may say that these are sown the same way, and afterwards grown in a precisely similar manner as the Primulas, and in the same sort of soil; in fact I generally mix up soil for the three sorts of plants at one time and all alike, and I have found these do well with it after a trial of some years. For the Primula it used to be the rule to use peat and leaf mould for reasons I cannot understand, as I could not produce that sturdiness of growth and flowering qualities so necessary to these useful flowers, and somehow or other they so very frequently rot off at the neck of the plant; and, again, a mixture of this nature soon became soured and quite out of a state for plant growth.

The Cineraria is improved in health and vigour if a little charcoal dust is mixed with the soil, and when the plants are in their last shift they will do better than in frames if the plants are stood in a shady border or a bed of coal ashes; this will be in the months of August and September, when they grow rapidly. With regard to the sowing of the seed, for very early plants they ought to be well advanced by this time, say good plants in 60-sized pots; but for small useful decorative plants the seed should now be sown, and they will be good plants by the autumn. As to the

Calceolaria, this is a somewhat hardier sort of plant, and the latter end of July is a good time to put in the seed. No heat is needed for these, but after sowing the seed and treating the seedlings similar to those directed above, they may be placed in a handlight in a shady corner, the pot or pan standing clear from the ground to prevent slugs reaching the seedlings, for which they have a special liking. These being very small, a little more pains will be necessary in pricking them out, so as to ensure their being fastened in the soil. Calceolarias do not grow fast at first, but when once established, and during the winter months, they make rapid progress. These as well as the Cinerarias must not be allowed to become potbound until they occupy the flowering pot. Again, the Calceolaria must have the centre shoot taken out in the spring; this allows the side shoots to come along, which form the plant. They, too, like frequent sprinklings of water over the foliage when in a greenhouse temperature, and just before the plants have attained their growth a little weak guano water may be given them three time a-week, and both in winter and summer let the plants stand upon a moist bottom.

The plants are much more liable to suffer from dryness than damp, and they should always be kept as near the glass as possible, and in a temperature of 45°, or even less, they grow very fast. The Primula flowers in winter and spring, the Cineraria follows closely, and the Calceolaria in May and June. —Thomas Record.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

The continued drought is telling upon all crops. Even the Potato plants in the fields are far from satisfactory; the segments of the leaves are curled-up instead of being spread-out stiff, as they usually are in quite healthy plants, and unless copious showers of rain fall soon it will be a serious matter for those whose living depends on their crops. The total rainfall at Loxford so far for this year been but 6.65 inches, and 2.29 inches of that quantity fell in January.

As the earliest Peas and Potatoes were quite at a standstill they had a good soaking of water. In watering Peas the water should not be applied with force to the stems, as this treatment is apt to injure the plants. The best way is to draw a drill close to the rows, and to fill the drills twice with water; the moisture will permeate the ground from each side of the rows sufficiently to moisten it where the roots are. After watering it is best to mulch the surface of the ground with rotted manure. If this cannot be done the drills referred to may be filled-in, which will arrest evaporation.

It is bad policy to apply water to any of the out-of-door

crops, and then to leave the surface to be acted upon by the sun; indeed, much injury is done to plants that have just been put out if water is applied with force from a coarse rose. The surface of the ground, even after the first application, is made impervious to atmospheric influences, and future waterings will make matters worse. In the first instance the watering should be done in a careful manner. If there is but little to do and plenty of time to do it, a fine rose may be used on the water-pot, as the more gently the water falls on the ground the better, but in nine cases out of ten it is necessary to push through the work as quickly as possible, and a coarse spreader must be used. The operator ought to keep his hand low, raising the bottom of the pot just above the ground, which will cause the water to flow gently. Mulching is certainly the best preventive of evaporation. Where this is not possible, the Dutch hoe run through the ground when the surface has partially dried is beneficial.

Planted-out Brussels Sprouts after watering the ground. It is much better to plant at night, so that the plants are in the ground at least twelve hours before they suffer from the sun; it is also worth the trouble to sprinkle them overhead two or three times a day. Salad crops, especially Lettuce, should be well supplied with water. The hoe ought to be kept at work wherever there is any appearance of weeds. It is not possible to use the hoe too much.

PINERIES.

Those who were fortunate enough to obtain good suckers last month and potted them as directed, must now see that the plants are kept growing. Pines do not show the effects of bad treatment so soon as many other plants, but they do suffer nevertheless. Very little artificial heat will be required now. The house ought to be shut up at 5 P.M., or even before that, much depending upon the position of the house, the construction of it, whether span-roof or lean-to, and other circumstances. It is absolutely impossible to lay down a hard-and-fast rule. Take an illustration: Some houses here have an aspect south-east; these are lean-to's, and the sun is off them before 4 P.M. They may be shut-up at that hour, whereas if they were south-west the sun would act upon them until six, or a span-roof running north and south would catch the morning sun at 5 A.M., and the setting rays at 6 P.M. In the last instance a little air should be admitted very early in the morning, and the house ought not to be shut-up altogether until six at night. Pine houses ought to be fired freely during the next three months. We have not put up any shading yet in the fruiting house, as the plants do not seem to require it. Fruit that is ripening ought to be very slightly protected from the midday sun. Abundant supplies of moisture ought to be kept up by evaporation in the succession houses.

CUCUMBER AND MELON HOUSES.

Our Melons are rather late this year; the seeds were sown about the middle of January, and the earliest fruits are now just on the point of ripening. In other seasons we have had the fruit ripe about the third week in May; the same night temperature has been kept up, so that the reason must be found in a lower day temperature. In forcing it matters little how cold the nights are, this can be overcome by using more fuel, but no amount of artificial heat can balance the want of sun. In a clear day the temperature rises in a few minutes 10° or 15°, and by judicious air-giving it may be kept up. Red spider, owing to so much artificial heat, has been prevalent, but has been easily kept under by syringing. The only evil that results from the use of the syringe is this—the water runs down to the base of the stem, is conducted there by the main stem itself, and not unfrequently the plants die off at the neck. This does not happen when the plants are put out on a raised mound like a molehill. The fruit is not left on the plants until it is fully ripe, but is cut and removed to a cool fruit room to ripen.

The Cucumbers up to the end of May have not been so productive as in previous years. We fancy that the character of the soil used to plant them in had more to do with this than the weather; it was light sandy loam, and what had been used previously was of a more clayey character. The roots speedily exhaust the mould in which they are growing, and must frequently be reinvigorated by rich surface-dressings. The plants must also be looked over about once in a week or ten days, and the growths thinned out; all old growths must be cut out and be replaced with young shoots. Syringe twice a-day, and sprinkle water about frequently. As much air as possible ought also to be admitted, but cutting winds must be avoided.

Figs in pots require similar treatment until the fruit shows signs of ripening, when the syringing must be discontinued. The pots also require to be surface-dressed with rotted manure and loam in equal proportions. Oranges grown for dessert purposes in pots, if the plants were not repotted in the winter, must also be surface-dressed. A mixture has been used here the last two seasons that acts like magic; it is composed of yellow loam, pounded charcoal, guano, and bone dust in equal proportions. The mixture is spread thinly on the surface of the pots, and is washed down by the waterings; sickly foliage assumes a deep green colour in ten days after the application. The trees are now syringed twice daily, the temperature of the house is the same as for Pines.

PLANT STOVE.

Climbers are apt to occupy too much space. When planted out as ours are, they shade the plants too much; and some of them, such as Clerodendron Thomsoniæ, shower down withered flowers on the plants beneath, and the decaying flowers cause decay on the leaves of valuable plants. Of course all this is avoided if due attention is given to the plants. Nothing is better than the Clerodendron as a roof plant, it has been the admiration of all visitors on entering the stove; the leaves are also offensive to insect pests. The blooming period is nearly over, when all the old wood will be cut out and be replaced with young growths. With the above may be named Bougainvillea speciosa. Many persons admire the large showy flowers of Allamanda Schottii; it requires plenty of space, and must be syringed to keep down red spider. The plants in pots have required abundant supplies of water and much moisture in the atmosphere to counteract the effects of the drying winds.

ORCHID HOUSES.

It has been necessary to open the front sashes on very hot days, as sufficient ventilation has not been obtained from the roof. Draughts are avoided by having permanent canvas shading nailed to the top and bottom plates. In this way all the air that is admitted passes through the canvas. It is not so on the roof; the canvas there confined the air, and sufficient was not admitted. The lath to which the canvas was attached has been brought down about 9 inches; this space being left quite open has much improved the atmosphere of the house.

We have placed Phalænopsis grandiflora and amabilis in fresh baskets. This class of plants require considerable supplies of water, and the sphagnum in the interior of the baskets is apt to become sour. This can either be removed by carefully picking it from amongst the roots, and replacing with fresh material if new baskets are not required. If it is necessary to use larger baskets the plants must be removed very carefully, and all dead and decaying roots removed; plenty of potsherds must be mixed with the chopped sphagnum used to fill the baskets. The moss ought also to be fresh, as the plants do not succeed well if that is not in a growing state.

In the cool house many Odontoglossums are starting into growth, and most of them have been repotted. These with Masdevallias and other plants may be syringed overhead if it can be done without injuring the flowers. If the cool Orchid house is exposed to the sun double shading is necessary to keep down the temperature.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Messrs. E. G. Henderson & Son, Wellington Road, St. John's Wood, London.—*List of New Plants and General Catalogue.*

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BURTON-UPON-TRENT.—June 16th. Mr. Wm. Shave, Bond Street, Sec.
JERSEY.—Roses June 16th, Autumn October 13th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.
YORK.—June 16th, 17th, and 18th. Mr. Jno. Wilson, 13, New Street, York, Sec.
GLASGOW.—June 16th, September 8th. Mr. F. G. Dougall, 167, Canning Street, Sec.
EXETER (Rose Show).—June 18th. Mr. T. W. Gray, Queen Street Chambers, Hon.-Sec.
FAREHAM.—June 23rd. Mr. H. Smith, Sec.
STOWMARKET.—June 24th and 25th. Mr. S. Prentice, Hon.-Sec.
REIGATE (Rose).—June 26th. Bushby Britten, Esq., Hon.-Sec.
CRYSTAL PALACE COMPANY.—Rose Show, June 26th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.
WISBEACH.—June 30th. Mr. C. Parker, Hon.-Sec.
MAIDSTONE.—(Roses), June 30th, at Vinters Park. H. Banstead, Esq., Hon. Sec., Rose Club, Mill Street, Maidstone.
NORFOLK AND NORWICH HORTICULTURAL SOCIETY.—Rose Show, June 30th. E. A. Field, Hon.-Sec.
BIRMINGHAM.—July 1st, 2nd, 3rd, and 5th. Mr. Quilter, Aston Park Sec.
SPALDING.—July 1st and 2nd. Mr. G. F. Barrell, Hon.-Sec.
BROCKHAM ROSE SHOW.—July 3rd. Rev. Alan Cheales and Charles Mortimer, Esq., Hon.-Secs.
SOUTHGATE.—July 3rd. John Miles, Esq., Hon.-Sec., Southgate, N.
GRANTHAM.—July 6th and 7th. Schedules, &c., from Mr. Lyne, Bookseller.
DURHAM AND NORTHUMBERLAND.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.
WINTERTON.—July 7th and 8th. Mr. McCallum, Sec.
FROME (Rose).—July 8th. Mr. A. R. Baily, Hon.-Sec.
KILSBY.—July 8th. Sec., Mr. C. E. Bracebridge.
RICHMOND.—July 8th. Mr. A. Chancellor, Hon.-Sec.
NOTTINGHAM.—Rose Show, &c., July 8th, 9th and 10th. Apply to Alfred Kirk, Municipal Offices, Nottingham.
OXFORD (Roses).—July 9th. Mr. C. R. Ridley, Hon.-Sec.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Royal Horticultural Society's Show (*W. E.*).—Our reporter necessarily was there early, and the prize cards were not all placed. Those who ascribe motives usually betray themselves. There was, further, a misplacement of cards; for instance, the exhibitor's card attached to bunches of green Muscats was removed altogether.

Summer-pruning Plum Trees (*R. M.*).—All the shoots which grow more than an inch or two ought to be stopped at the third leaf, pinching off the point of the shoot when it has made that number of leaves; but the short stubby shoots are not to be interfered with, but left their entire length, providing the growth of this year does not exceed an inch or two. When that is exceeded cut them back to three leaves. The leading shoots or continuation of the branches are not to be stopped, but trained-in their full length. If shoots are not wanted for extension, the space being covered, stop the shoots from their extremities the same as the others.

Rose Leaves Diseased (*E. L.*).—They are affected by the orange fungus, Puccinia rosæ. The remedy is to dust over the leaves with flowers of sulphur.

Clematis (*E. B.*).—Miss Bateman (white) and Albert Victor (deep lavender) are both of them beautiful varieties; either of them will suit you.

Peas (*H. S. F.*).—We have no sample of Peas from you.

Mr. J. Coomber.—Our report states your direction correctly, Highgate. It is the Royal Horticultural Society in the advertisement of prizes states erroneously Reigate.

Strawberry House (*Infelix*).—We do not approve of your proposed house as represented by the sketch, for the plants will be at too great a distance from the glass, and deprived of the air playing freely around them, which is essential for the well-doing of forced Strawberries. A half-span with the ends pointing east and west, fitted with shelves to suit the pitch of the roof, which should be a sharp one to admit of watering the plants from the back, and these shelves having soda an inch thick reverse side down, will last a season. In vol. vii. of the *Journal of Horticulture*, page 354, is given a section of the Strawberry house at Enville, and a house of this kind we advise in preference to your proposed one, which we feel sure will not answer for the purpose of early fruit, which is most desirable.

Dendrobium nobile (*Subscriber*).—That is the name of the Orchid which you sent us. It is not possible to flower it in winter with a night temperature of 50°; but it will flower in April or May. Give the plants abundant moisture during growth, and when the growth is complete gradually reduce the supply and expose the plants more fully to light and air, so as to thoroughly ripen the growth. In winter keep dry, affording moisture only to keep the stem from shrivelling. Poinsettia pulcherrima may be flowered successfully in a house with other means, such as frames, for forwarding the plants.

Melons Swelling Irregularly (*F. H.*).—It is a consequence of the fruit being upon one primary vine, the sap not being equalised. It may be obviated by having more than one primary shoot to a plant—as many to each plant as you wish fruit. Your gardener will meet your wishes if you explain them to him. We take three and four fruits from a plant, and by having each fruit upon a principal vine we experience no difficulty with the swelling.

Tricolor Geraniums (*M.*).—You probably grow them in a very airy dry house, which they do not, especially at this season, do well in. Give them a frame or pit, and a distance of about a foot from the glass, watering moderately, shifting into larger pots as required, but not giving large shifts, admitting air moderately, and affording slight shade from bright sun.

Rose Leaves Brown (*S. F.*).—The root action is defective. Water the roots copiously with tepid weak liquid manure, and keep mulch over the surface of the soil.

Liquid Manure of Fowl's Dung (*E. G. G.*).—For culinary vegetables mix a peck of the dung with thirty gallons of water, and for flowers twice that quantity of water.

Rose Leaves Brown-surfaced (*S. C.*).—No insect causes the mischief, but defective root action. See our advice to another correspondent.

Radishes in Hot Weather (*Gardener, Croydon*).—Sow as usual the oval-shaped scarlet, and water plentifully every day.

Tarred Cord (*Mrs. M.*).—It is not injurious to plants tied by it.

Tree Ferns from New Zealand (*S. J. R.*).—Write to Mr. Stevens, auctioneer, King Street, Covent Garden.

Potato Fungus (*P.*).—The Potato plant had the well-known fungus upon it in small quantities, but the specimen was very bad. The *odour* itself is quite characteristic of the *presence* of the fungus.—W. G. Smith.

Grubs at Strawberry Roots (*C. J. H.*).—We have nothing to add to the reply we made. Your hand-picking was very successful, and if every sufferer would do the same extermination would be nearer effected.

Insect Pests (*Adams*).—The discoloration of your Bean leaves is due to the presence on their under sides of a species of thrips.—I. O. W.

Insects (*R. H.*).—Jefferson Plum. A moth is parent of the maggots. The Coddling Apple insects are green flies, aphides, and so are those on the Damson leaves.

Names of Plants (*C. M. M.*).—The Elder is Sambucus laciniata, or Cut-leaved. We cannot name varieties of florists' flowers. (*D. Drake*).—Yellow one, Trollius europæus; white, Saxifraga Gmelini or hypnoides; the tree, Platanus orientalis. (*A. T.*).—The plant you have raised from seed of the Locust fruit is probably Hymenæa latifolia, Broad-leafeted Locust Tree.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY AT RAILWAY STATIONS.

At least once a month we read or hear of some wretched bird which has been mutilated in its plumage on its way to or from a show. It has its tail pulled out, or it loses some feathers in some particular place, or it has something overturned on it which spoils its plumage, or it is shaken up and knocked about, and so becomes seedy. Then long faces are pulled, and secretaries are blamed, and certain parties are suspected, and all kinds of suspicions are vented on innocent heads. We have an idea—it may be an idea only—that much of this mischief takes place at railway stations. We do not mean that it is done by railway officials purposely—far from it; but we believe that often baskets arrive at stations swaddled-up in linen and canvas, labelled "with great care" and "live birds." Well, we fancy, perhaps our good railway servants are sometimes seized with a craving—they may be amateur fanciers themselves, or may have friends in the fancy line—to see the inmates of such baskets, and, with purely good intentions, let the birds have a run in the office, giving them exercise and at the same time the said officials opportunity for inspecting the birds. We do not for a moment wish to be misunderstood. Doubtless there are some few evilly-disposed individuals who would pluck out a bird's tail if they came across it, or shake it up to prevent his or her winning, and doubtless such things are done, but such customers we think and hope are few and far between; while we happen to know that mutilations of plumage do occur at railway stations, especially junctions, where birds have to stay sometimes several hours, and it is at these places we believe that many of the birds lose their plumage, and are consequently prevented from winning. Not purposely—far from it, but simply from the hands of people who, having opened a basket to see the contents, are unable to put them back again, and in the desire to do so speedily a scuffle ensues, and the bird proceeds on its journey having, like the memorable "Bo-peep," left its tail behind it.

To show that such things are done, and that we are in a way warranted in coming to the conclusion we do, we will quote two or three cases which have come under our own eyes, and which at the time we felt should have been shown up. Still, as the day is past we will not give now the places' names, but merely narrate the facts. So firstly, then, we happened one day at the end of November to be staying at a large station hotel in a midland county. We strolled on to the platform for an evening paper. It was the vigil of the Birmingham Show. As we passed the parcels' office we heard a peculiar sound as of some bird cackling, as they do when pursued. We happened to know the clerk a little, and so in we went. One peep round showed us how the matter stood. There was an empty basket on the floor, there were five or six porters looking on, and there was a clerk running here and there chasing a Spanish cockerel. It flew on the shelves, it flew on the table, it flew over the men's heads. We had no idea Spanish cocks were so wild, we ventured to say. "No more 'ad we," said one of the men there assembled; "we only took the beggar out to look at him and give him a run. He has come all the way from Somersetshire, and now he kicks up this row." Just at this moment the chasing clerk made a dab at the chased cockerel and seized him by his sickles; out they came, and away the bird was off again. At last he was caught and replaced in his hamper and forwarded to Bingley Hall, where he was highly commended, and we do not hesitate to say he would have been in the list but for his absent and seriously ruffled remaining feathers.

Once more: we were at a great junction the day before the Northampton Show. At the said junction there was on the platform a pile of baskets waiting to go on to the Show. At the top was a peculiarly striking one. It was of white wicker, and had a broad green stripe round it [who recognises this?]. This struck our eye, and so it seemed also that of one of the bystanders. He seemed wild to see the contents of the green-striped basket. He peeped in at the sides, and he peeped in at the lid, but apparently he could not satisfy his longing eyes, so he gave one tremendous tug to the lid to have a good satiating look, and in a moment out flew a Duckwing Game cock. It was off like an eagle. The porters chased it, the people chased it, and on it flew till it got outside the station, and escaped into a field. The train steamed in, and the train steamed out, taking with it all the pile of baskets, but leaving behind one empty—a white one with green stripes, and when the cock was recaptured the last train had gone, and the emerald-barred casket was "too late for exhibition."

Again: we ourselves were taking some birds to a show. We had to wait at a junction, and we seized the opportunity for taking "a glass of bitter, if you please," having previously

placed the birds in the office. The refreshment ceremony over we returned to our baskets. Ah! some one making an aperture between the lid and the side to get a view of our cup-winners to be. How short-sighted he must be! he seems to want to get his whole head in, we thought. Ah! in goes a stick. A dab here and a dab there, and out it comes again. We lay our hands gently on the individual's arms, and beg to know the cause of his anxiety. "We saw a hegg." Quite right to say *saw*, for it was not then to be seen! The porter, a poultry-fancier in embryo perhaps, had seen the egg. Perhaps with a three-minutes-boiled dainty in his eye for breakfast, perhaps with a hope of obtaining a cup-winner, this servant of the railway had made several grabs at the egg, and in his endeavour to fish it up, or, perhaps, only to get it in better perspective to see its colour (?), had broken it, and the inhabitants of the basket quietly allowing the contents of their produce to foul their plumage and stick their feathers together lost the cup, as we were afterwards told, "for want of a washing."

We could quote more cases, but enough. We have shown that we ourselves know of a bird losing its tail, of a bird being too late, and of a bird being dirtied in his plumage. In each case the mischief was done at a railway junction close to the neighbourhood where the show was to take place, and done unintentionally. We know of no remedy that we can suggest to be really effective; we merely name these cases to show that exhibitors must not always think when the plumage of their birds is injured that it is done purposely by some jealous fellow exhibitor to prevent its winning.

There have been several new baskets invented of late with curtains and fittings to prevent the inmates being touched, and we strongly advise the use of them to those exhibitors who do not personally take their birds to shows or send them with their servants; and we also think the plan Mr. King, the worthy honorary secretary of the Oxford Show, suggested and, we believe, carried out, a good one—viz., of sending some responsible men on the day the birds are due at the show to the chief neighbouring junctions, that they may keep an eye on and hasten the transit of the baskets which come unaccompanied by attendants, both on their journey to and from the exhibition.—W.

POULTRY HAUNTS.—No. 2.

MR. W. O. QUIBELL, NEWARK-ON-TRENT.

I AM ashamed to think how long a time has passed since the idea first struck me of giving a notice of some of the homes of our fanciers from whence come some of the most celebrated winners of prizes at our great poultry exhibitions, and of gleaning such information as might be interesting to those who like myself, while not going in for it extensively, are yet more or less affected by the poultry mania; but although I have been several times asked what I was about in not carrying on my project, the claims of other matters, especially of those pertaining to flowers, have prevented my doing so. I may claim, I hope, a little consideration from the readers of our Journal, to whatever portion of it they look, when I plead the labour and correspondence that have been entailed on me in the attempt to form a Horticultural Club, which is now, I am glad to say, an accomplished fact, and which will form, I hope, a rallying point for all interested in those pursuits which our Journal advocates.

Is it strange that we should gravitate towards those things in which we are especially interested, or that we should find out that we can overcome difficulties when they are to be reached? I have been and am an admirer of Houdans. I like their appearance, though some call them ugly. I like them on the table, for they are amongst the whitest and best of fowls—so different from Brahmas, concerning which I saw a letter the other day from one who had kept them, that he would as soon think of putting an owl on his table as one of them; and I have until the present year liked them for laying. I made my complaint about them, but I am inclined to think that I have fed mine too well, and that was the cause of their being so tardy in beginning. They have gone on very well since they began, although my yard was reduced by one-half owing to a violent outbreak of roup consequent on the long cold winter; and I hope that they will redeem their character with me next season, when, if I am spared, I hope to speak better things of them. Well, I had enjoyed a long morning at Belvoir, of which I shall hope to have something to say shortly, and was on my way to Manchester. But would it not be possible to stop at Newark for two or three hours and see Mr. Quibell's fowls? It was worth the trial. Mr. Ingram added to his many acts of courtesy by sending me into Grantham, and as the trap drew up at the station the train for Newark ran in. I was just in time to take my ticket, shoulder my bag and step in. When I reached Newark I started off for Mr. Quibell's, and as I came near to where I thought it was I asked a servant girl whom I met the direction in which to go. This she did not tell me, wisely, but pointing to a gig which was just detained at the railway crossing by the train—"That," she said, pointing to the gentleman in it, "is Mr. Quibell." Thanking her for the information, I accosted him, and was told that he was very sorry that he was obliged to go into the country, but that he had left orders for me to see his birds, and that his poultryman would give me any information he could. Inquiring my way, I soon found out the locale, which was none other than the old Castle of Newark, which is occupied by Mr. Quibell, who is an agricultural chemist. I was soon introduced to the poultryman, and we were quickly deep in conversation upon our favourites. The old birds were here penned-off for breeding, but the younger birds were at some little distance in the country, so that I did not see them. As nearly everywhere breeding was late this year, and I fancy that this will tell by-and-by. However, there is this to be said for the French breeds, that early chickens are not so great a desideratum as with some breeds. They grow so rapidly that they soon make up for the lateness of hatching. The largest bird I ever exhibited as a cockerel (weighing nearly 9 lbs.) was not hatched until the 23rd of April; and Mr. Quibell's man coincided with the opinion expressed to me by Mr. Wood, that early hatching was not so needful with either Houdans or Crêve-Cœurs.

As the fancy of judges varies, Mr. Quibell determines to be *utrumque paratus*; and if they prefer the lighter, which is, after all, the true type of Houdan, he has a fine male bird paired off with some light hens, while in another pen he has the darker and more generally preferred type. The bird that has for two seasons won the Crystal Palace cup was here, and although it is a bad time of the year to see birds in the brilliancy of their plumage, yet he looked uncommonly well, not "bearing his honours meekly, but as if, having already conquered, he was determined to go in and win." In comparing the strains of the three most successful exhibitors of Houdans that we have I fancy that one can see a distinction in them. Mr. Wood's birds, especially his male birds, seem to have the advantage in size. I had a monster bird of his which weighed at one time quite 9½ lbs.; but then I think this size was obtained by a sacrifice of refinement—legs too heavy, and the body too much inclined to settle down on them instead of being well up. I have seen no hens that I think equal to my friend and neighbour Mr. Dring's; and although I know he has had a very long price for one of his male birds, I cannot say that I think his strain of these as already shown equal to Mr. Quibell's. There is a refinement of limb combined with excellence of crest, beard, &c., which in my poor judgment fully justifies the high position they have attained at some of our chief exhibitions. As to the vexed question of comb, I cannot agree with those judges who wish to see them so open. It is not the characters given to them by the French writers on poultry, who ought to know their own breeds, one would think. The central boss, or whatever we may call it, like a strawberry ought to be present; but the comb itself is, according to Jacques, of various forms, and does not follow so rigid a rule as that of the Crêve-Cœur.

While Mr. Quibell's older birds are at Newark the chickens were at some distance from the town, having the benefit of a grass run which they could not have in the old Castle yard. What prize-winners there may be amongst them I know not; but of this I am sure, that I would not desire for my own stock a finer or better bird than his cup bird.

In the matter of feeding and care I find but little difference. All Houdan breeders acknowledge their hardiness and their capacity for grubbing for themselves, and, despite the disappointment I experienced this year, I shall still cling to them as all in all the kind I like best.—D., *Deal*.

SCHEDULES OF SHOWS.

BOSTON holds its sixth Exhibition of poultry, Pigeons, Rabbits, and cage birds on June 22nd and 23rd, at the same time as the horticultural show. Poultry have six £3 pieces of plate, Pigeons three value £2 each, and Rabbits one of 30*s*. How much better it would be to give the cash instead of pieces of plate of so small value. The birds are to be shown on the single-bird system. Dorkings of all colours and Cochins of all colours have to compete together, and the Committee do not deserve an entry in these classes until they break them up more. Black Hamburghs have no class. Crêves and Houdans are well taken care of. There is no variety Duck class, and Game Bantams, except Black or Brown Reds, have to go into the variety Bantam class. The poultry entry fee is 4*s*. per pen. The Pigeons are also to be shown singly. Carriers are magnificently seen after; they have six classes, a cup and eighteen prizes. Tumblers have four classes and Pouters two, one of which we are glad to see is for Whites. The entry fee is only 2*s*. 6*d*. The Boston people evidently love Pigeons better than poultry. Rabbits, too, have thirteen classes with three prizes in each class, of which thirteen classes four go the Lop eared. The entry fee is 2*s*. 6*d*.

The rules tell us "gentlemen of acknowledged ability" will award the prizes. Why are their names not announced? That is blot No. 1. Each pen of poultry—*i.e.*, each individual cock or hen, must be in a separate basket—blot No. 2. The rest of the rules are pretty much as usual, except that tickets are given to exhibitors, which is a most proper arrangement.

The Essex Agricultural Society meet this year at Brentwood. The poultry schedule is very limited. Dorkings and Cochins again have only one class each. It is very shortsighted of committees not to give at least two Dorking classes; agricultural societies should especially try to increase the cultivation of the *par excellence* table bird. Hamburghs have one class! Ducks, too, have one class! Brahmas and Game two each. The prizes are £2 and £1, and the entry fee is 5*s.* per pen. There are four £3 3*s.* silver cups, and money can be taken if preferred. This is a good rule. The old story—"Gentlemen of acknowledged ability" will be engaged, but no names are given. The prizes will be paid within fourteen days after the show. We are glad to learn this, as we do not think some of the prizes at the late Essex Show at Stratford were ever paid at all. And we observe one new and useful rule: "Special passes will be supplied to exhibitors on their written application for them." The total amount of money spent on the poultry prizes is nearly £50. We cannot help saying we think it might have been expended in a more enticing way than it has been. The entries close on June 15th. We see no mention made of baskets, and so we conclude double baskets are as much admissible as single ones.—W.

P.S.—Since writing the above, we have seen that the Judges are now advertised in these columns for Boston—viz., for poultry, Mr. Hewitt; Pigeons, Mr. Massey; and Rabbits, Messrs. Hudson and Allison. "Better late than never!" We only wish for the Society's sake they could have been duly announced on the schedulee.—W.

CROWLE SHOW OF POULTRY, &c.

This, June 1st, was an excellent Show, the attraction of so many articles of cutlery, timepieces, tea services, &c., proved so great that many of the best exhibitors put in an appearance. Turner's pens were used, and arranged on three sides of an excellent field not a great distance from the station.

Dorkings came first, and Silver-Greys were first, with Dark Greys second and third; a fair class. In *Cochins* first and special were Whites; Buffs coming second and third. In *Spanish* the winners were very good and well shown. Except the winners Light *Brahmas* were poor, the Dark variety being far ahead of them. *Game* were good, and almost every pen was noticed, the extra going to a capital Black Red. Second was a good-coloured Brown Red, but sadly out of feather; the third a Brown Red, we preferred to the second; several other good birds justly received notices. In the next class first and third were Duckwings, and second Pile. Black or Brown Red hens were the largest class, the whole being Brown Reds and the class good. In the following class first was a handsome Duckwing, second a Pile, and third a Duckwing. *Hamburghs* came next, and these were very good, the cup going to a grand pen of Gold-spangles, and almost every pen was noticed in this section. In Black or other Red Game *Bantams* all the winners were Black Reds, the cup for this section being awarded here, though the cock in the winning pen had one sickle not quite at length; the hen was a gem. Second was a grand cock, but only a moderate hen; and third a fair pen. In single cocks first was a grand Pile, which has improved much of late; the second and third were also capital Piles. Single hens, Black and Brown Reds, were first a perfect Brown Red, second and third Black Reds, all good. In Any other colour of hens first was a Pile, and second and third Duckwings. Blacks won all the prizes in the following class, these being good in all respects. *French* fowls were poor. *Polands* were not numerous, but very good; first special Golden, as also the third, and second Silvers. The Selling class was large, but some of the winners were very poor, the first-prize pen of Brahmas being especially scraggy. *Ducks* were not numerous, the Variety class being by far the best.

Pigeons were a splendid entry, the birds being shown singly. In *Carrier* cocks the first and second were Blacks, grand in all points; a well-known winner having to be content with third. Hens were equally good, and the winners also Black. In *Pouter* cocks the first and second were Blues, and third White; nearly every bird was noticed. In hens the winners were all Blues, and a capital lot. Almond *Tumblers* were very good. In the next class first was a neat Short-faced Black Mottle; second a Long-faced Black Bald; and third a Short-faced Red Mottle. *Barbs* were a good class, a Dun being placed first. This bird looking well in the earlier part of the day, but was watery in the eyes towards night. Capital Blacks were second and third. In foreign *Owls* first and second were Blue, and third White, three good birds. The first-prize *Turbit* was a little large, but otherwise good, a Black; second was a Red, very good and small; and third a Silver, good but somewhat large, the whole being clear on the thighs, many otherwise good birds being defective in that respect. *Jacobins* were a good class, the first and third Reds, and second Yellow. Some of the birds were cut a little lower on the throat than we like to see. *Trumpeters* were all of the foreign variety; and *Fantails* a moderate lot of birds, the winners standing quite out. The winners in *Nuns* were Blacks, and there were also some good Reds in the class. *Magpies* were a very good class, the winners Red, Yellow, and Black respectively. The *Swallows* and *Archangels* being also good. In *Dragoons* Blues won, the first-prize bird being in our opinion perfection in both head properties and colour. In *Antwerps* there were two classes, the first in Long-faces going to a Blue Chequer; second to a Red Chequer, as also the third. Short-faces were a good class, the winners being Silver Duns. There was very little choice in our opinion between the first-prize Powder Blue and second Silver in English Owls; the third going to a Blue. In the Variety class a most beautiful Crescent-breasted Swiss first; a Black Turbiteen second; and a Blondinette third. A capital pair of Almonds were placed first in the Selling class, and many other pens were noticed.

Cage Birds were but a small show; but there were some good birds.

There were four classes for Rabbits, and the prizes being good we were surprised to find the entries poor, there being only thirty-six entries, although some were very good, especially Mr. Irvine's Lop and Mr. Hudson's Silver-Grey. From some cause or other the judging did not commence till near twelve o'clock, and the consequence was that they were scarcely finished at four in the afternoon, and some were removed within half an hour of the arbitration being complete.

Dorkings.—1, W. H. King, Sandfield, Rochdale. 2 and *c*, W. Morfitt, Goole. 3, W. Harvey, Sheffield. *hc*, J. Chester, Thorne.

Cochins.—2, J. Boyle, Manchester. 3, W. Harvey.

Spanish.—1 and *hc*, R. Newbitt, Epworth. 2, H. Beldon, Goitstock. 3, J. Powell, Bradford.

Brahmas.—*Light.*—2, H. Beldon. 3, W. Whiteley, Sheffield. *hc*, R. E. Horsfall, Liverpool. *Dark*—1, W. Whiteley. 2, J. F. Smith, Cherry Mount, Sheffield. *hc*, Rev. A. G. Brooke, Shrawardine, Shrewsbury; J. F. Smith. *c*, W. T. Millet, Liverpool.

Game.—*Black-breasted and other Reds.—Cock.*—1, S Matthewa, Stowmarket 2, A. Sugden, Cleckheaton, Normanton. 3, H. E. Martin, Sculthorpe, Fakenham. *vhc*, W. Perrin, Nantwich, Cheshire. *hc*, J. Mason, St. John's, Worcester; J. Chester, Nantwich, Cheshire; J. Cock; J. R. Fletcher, Stoneclough. *c*, W. Anderson, Epworth; J. Taylor, Sculthorpe. *Hen.*—1, J. Chesters. 2, H. E. Martin. 3, W. G. Waters, Elsham. *vhc*, J. R. Fletcher. *hc*, C. Foster, Crowle; S. Matthew; H. Beldon; S. Harrison, Epworth; A. Cameron, Epworth. *c*, J. Cock.

Game.—*Any other variety.—Cock.*—1, J. A. & H. H. Staveley, Driffield. 2, W. G. Waters. 3, H. E. Martin. *hc*, J. R. Fletcher. *c*, S. Matthews. *Hen.*—1, H. E. Martin. 2, E. Winwood, Worcester. 3, G. Yates, Thorne. *hc*, H. Beldon; H. Winter. *c*, S. Matthews.

Hamburghs.—*Golden-spangled.*—Cop and 3, H. Beldon. 2, H. Pickles, Earby, Leeds. *hc*, T. P. Carver, Laughorne, Boroughbridge. *c*, G. Holmes, Great Driffield; J. Robinson, Garstang. *Silver-spangled.*—1 and 3, H. Beldon. 2, J. Robinson. *vhc*, H. Pickles. *hc*, G. Holmes; J. Robinson.

Hamburghs.—*Golden-pencilled.*—1, T. P. Carver. 2 and 3, H. Beldon. *vhc*, H. Pickles. *hc*, J. Robinson. *Silver pencilled.*—1 and 3, H. Beldon. 2 and *vhc*, J. Robinson. *hc*, H. Pickles.

Game Bantams.—*Black-breasted and other Reds.—Cock.*—Cup, Mrs. E. Newbitt, Epworth. 2, A. Sugden. 3, A. Smith, Northowram, Halifax. *vhc*, W. Shenton, Lancaster. *hc*, R. R. Plumtree, Epworth; A. C. Bradbury, Nuthall, Nottingham; J. R. Fletcher. *c*, T. S. Stevenson, New Bridge, Beverley. *Hen.*—1, Mrs. E. Newbitt. 2, J. Clifton, Lindholme, Hatfield. 3, W. A. Wressell, Crowle. *hc*, R. R. Plumtree; A. Sugden; J. R. Fletcher.

Game Bantams.—*Any other variety.—Cock.*—2, Mrs. E. Newbitt. 3, T. Dawson & Son, Epworth. *vhc*, R. J. Hartley, Altrincham. *hc*, A. Smith, Northowram; A. C. Bradbury. *Hen.*—1 and *vhc*, T. Dawson & Son. 2, J. R. Fletcher. 3, W. F. Entwisle, Westfield Wyke, Bradford. *hc*, Mrs. E. Newbitt; T. Dawson & Son.

Bantams.—*Any variety except Game.*—1, H. Beldon. 2, J. Mayo, Gloucester. 3, T. Cropper, Bacup. *hc*, W. G. Waters; J. Earnshaw, Rotherham; A. C. Bradbury; J. Clarkson, Birmingham.

French.—*Any variety*—1, W. Cutlack, jun., Littleport, Isle of Ely (Crève-Cœurs). *hc*, J. Wicks, Appleby, Brigg; H. Grant, Bradford (Houdans and Creve-Cœurs).

Farmyard Cross.—1, C. Antey, Ealand Warpings. 2, G. Smith, Crowle. 3, G. Robinson, North Fordingham. *hc*, J. B. Hepworth, Hatfield; T. Wroot, Eastoft; J. Smith, Crooks Moor; T. J. Sayles, Warpings.

Any other Variety.—Cup and 2, H. Beldon. 3, A. & W. H. Silvester, Sheffield.

Selling Class.—1, Wells & Bray, Winterton. 2, R. Medley, Sheffield. 3, W. Perrin, Nantwich. *hc*, J. Clifton; Mrs. Peet, Sharnbrook; H. Beldon; J. B. Hepworth; A. & W. H. Silvester; Simpson & Dodds, Bedale; J. M. Atkinson.

Ducks.—*Muscovy.*—1, J. J. Brown, Althorpe. 2, S. C. Brunyee, Crowle. 3, Miss Spilman. *Any other variety.*—1,—Snell, Barrowden, Stamford. 2, A. and W. H. Silvester. 3, A. C. Bradbury. *hc*, W. Bygott; A. C. Bradbury.

PIGEONS.

Carriers.—*Cock.*—Cup, J. Denkio, Sheffield. 1 and 2, R. Fulton, Brockley, London. 3, E. Horner, Harewood, Leeds. *hc* and *c*, H. Yardley, Birmingham. *Hen.*—1 and 3, R. Fulton. 2, H. Yardley. *hc*, J. E. Crofts, Blyth, Worksop. *c*, H. Yardley; E. Horner.

Pouters.—*Cock.*—1 and 3, R. Fulton. 2, W. Harvey, Sheffield. *hc*, J. Hairsine, Hull; W. Nottage, Northampton; J. E. Crofts. *c*, W. Harvey; H. Yardley; E. Horner.

Pouters.—1, E. Horner. 2 and 3, R. Fulton. *hc*, W. Harvey; H. Yardley. *c*, W. Harvey; W. Nottage; J. E. Crofts.

Tumblers.—*Almond.—Cock or Hen.*—Cup, H. Yardley. 2 and 3, R. Fulton. *hc*, H. Yardley; A. & W. H. Silvester; J. Gardiner, Preston; E. Horner. *Any other variety.—Cock or Hen.*—1, R. Fulton. 2, W. Tedd, Erdington. 3, A. and W. H. Silvester. *hc*, R. Fulton; H. Yardley; A. & W. H. Silvester. *c*, W. Tedd; H. Yardley; E. Horner.

Barbs.—*Cock or Hen.*—1, R. Fulton. 2, H. Yardley. 3, E. Horner. *hc*, R. Fulton; W. Harvey; R. White; E. Horner. *c*, W. Harvey; H. Yardley; E. Horner.

Owls.—*Foreign.—Cock or Hen.*—1, L. Horner, Crayford. 2, R. Fulton. 3, H. Yardley. *hc*, E. Horner. *c*, G. Richardson, Guilder, Rochdale.

Turbits.—*Cock or Hen.*—Cup, R. Fulton. 2, Miss F. Seamor, Leeds. 3, H. Yardley. *hc*, W. Tedd; G. H. Pickering, Driffield; W. Harvey; A. & W. H. Silvester; T. S. Stephenson.

Jacobins.—*Cock or Hen.*—1, J. Blanchard. 2, R. Fulton. 3, T. Holt, Bradford. *hc*, R. Fulton; J. Blanchard; J. Earnshaw; T. Holt; E. Horner. *c*, W. Harvey.

Trumpeters.—*Cock or Hen.*—1, W. Harvey. 2 and 3, R. Fulton. *hc*, W. Harvey; E. Horner. *c*, W. Harvey; A. A. Vander Meersch, Tooting.

Fantails.—*Cock or Hen.*—1 and *c*, J. F. Loversidge, Newark. 2, E. Horner. *hc*, A. Smith, Northowram; H. Yardley.

Nuns.—*Cock or Hen*—1 and 3, E. Horner. 2, W. Tedd. *hc*, Rev. A. G. Brooke; W. Harvey; J. Earnshaw; A. A. Vander Meersch; E. Horner. *c*, T. Green; Rev. A. G. Brooke; H. Yardley.

DARI FOR POULTRY.

IN answer to Mr. Brown's query respecting the above I will state my experience, having used it since the beginning of the year.

It is the greatest egg-producer I have ever used. I have given it to Brahmas and Hamburghs, and so far have only had one of the Brahmas broody. On leaving it off for a few days, for a change, the eggs fell off too, but on resuming it the eggs increased on the second day. I have had 253 eggs from five Black Hamburghs from February 6th to May 31st. The only fault I have to find with it is that it keeps the birds in bad condition: they would never lay on flesh with it alone. Both adults and chickens eat it readily. I trust some other fancier will give his experience with it.—GEO. RILEY.

DO YOU FEED YOUR BEES?

I AM often asked this question. I reply, Yes, sometimes. Some time since I wrote to you on the subject, but I do not remember from that time until now I have met with one who did not approve of feeding. However, I am not convinced that it is a good thing to be always stuffing bees, as some advise. If I continue to feed my bees so that they have the hive full of syrup, are they not restricted in the space for breeding?

I have several swarms this spring from hives that had no feeding all the winter. One poor neglected stock, taken in haste one day last year, was placed on an old iron stool covered with a bit of old sack, and a piece of sheet lead to hold it on; it is a very small straw hive. From this hive I have had three swarms this month—two of them good and one very small. They are all doing well, and the old stock seems as strong as ever.

I examined the first swarm last week and found honey; in fact it seems that they had filled the comb with honey as fast as they constructed the comb. Now, had I fed them what is to hinder them from filling all the comb, having no space left for young bees?

What has made me think it not good to feed as a rule is, that the bees are taught to look for the bottle instead of going abroad for honey.

Mr. Pettigrew argues that sugar at 3*d.* per lb. makes it profitable to feed, as if one pound of sugar would be converted into as much honey. This admission that sugar may be profitably converted into honey is a fine tale for honey-buyers; besides, it cuts the ground from under those who go honestly to work to produce honey for exhibition. A friend of mine told me to feed at all times when honey is scarce. On this principle it is no longer honey, but honey and sugar. If it is not so, will someone explain it?—J. C., *Brentford.*

[There is in this letter not only an honest ring and healthy tone, but a thick stratum of common sense. I am obliged to him for it, inasmuch as it gives me an opportunity of stating more fully what was meant by my remarks on feeding in the letter under the heading of "A Swarm of Bees in May."

In my remarks nothing was said about syrup being converted into honey. Bees cannot do this; and the attempts to make bees convert syrup into marketable honey have been loudly condemned by me in more places and occasions than one. Many of the readers of this Journal remember my letter on "Spurious Honey and Fraudulent Dealers" which appeared in its columns six years ago. Let me repeat that syrup made of sugar and water cannot be converted into honey, and anybody knowing this cannot honestly sell the one for the other. From a private letter from Ireland, as well as from the letter of "J. C.," I find that my remarks have been misunderstood. No one approves of "always stuffing bees," or "restricting the space for breeding," or of "teaching them to look for the bottle instead of going abroad for honey." I have never done this or taught other people to do it, and think it would have been better if "J. C." would quote my words instead of unwittingly misrepresenting my meaning. I am glad to learn that "J. C.'s" bees have done so well without feeding, and hope that he will have a good harvest of honey, and favour the readers of this Journal with a report of the same.

Now for a word of explanation. I said 4*s.* or 5*s.* worth of sugar given to a swarm makes it into a stock hive worth 30*s.* This, of course, was meant to be done in autumn, which has been explained again and again. We never make, nor can we make, honey hives from sugar; but in honey seasons swarms from honey hives may be put into empty hives and made into excellent stocks by feeding. Hundreds of stock hives were thus made last year, and now, like "J. C.'s" unfed hives, are doing well. This practice will become more general year by year. In seasons unfavourable for honey-gathering, stocks can be fed and kept in a state of health and prosperity at little expense by reason of the low price of sugar. As to swarms in May and June, I have no hesitation in saying that if the weather be unfavourable for honey-gathering at the time of swarming it is both wise and profitable to feed them.

Syrup wisely given to young swarms does not restrict breeding space, but creates it. Swarms on being hived have a passion for comb-building, and hence they convert almost all the sweets they can receive and gather into combs for breeding in. The anxiety of swarms to build combs and their industry at this work are not to be wondered at when we remember every first swarm has about two thousand eggs to set or waste every day. A few pounds of sugar given to young swarms help them very much. If "J. C." had given his third swarm, which he says was small, a few pounds of syrup on being hived he would have done something to bring it abreast of his second swarm which was so much larger. Here let me say that feeding second and third swarms on being hived is not so important as feeding first swarms, for in the second and third swarms the queens are not pregnant, and will not commence to lay for some days or till some combs have been built.

Slow and continuous feeding of stock hives during unfavourable weather in March, April, and May keeps them healthy and prosperous. Feeding swarms in May and June enables the bees to give their queens breeding spaces; and rapid autumn-feeding enables light and poverty-stricken hives to store up food for the winter months, and swarms to fill their hives with combs and store up food enough for their support.—A. PETTIGREW.]

BEES TRANSFERRING EGGS.

Mr. PETTIGREW has mentioned a case of egg-carrying on the part of bees, which, allowing for the absolute correctness of the facts (and there seems no reason to call it in question) is an important testimony to a long-doubted and long-denied statement. Every tyro knows that queen bees "lay far more eggs than they set." I have myself seen a queen lay eggs at random on the outsides of a cell after she had filled every available comb, laying two, or even three eggs in the same cell. In this case the bees around her simply devoured those eggs as fast as she dropped them. There was no carrying them off, nor in fact would it have been of any use to do so, as every comb was full. There have been times, too, in my long experience when it would have been very convenient had the bees transported worker-bee eggs to other and more suitable combs; but I have never to my recollection had even a suspicion of the fact.

Mere assertion of course is valueless. To go on "telling bee-keepers that working bees assist the queens in the distribution and setting of eggs" goes for nothing apart from the well-balanced and clearly-ascertained facts on ocular demonstration, which are the basis of all science. Had Mr. Pettigrew given us facts such as those now stated, neither Mr. Woodbury nor Mr.

Lowe, nor anybody else, would have repeated the assertions of all scientific bee-keepers to the contrary, without some hesitation at least, even if they were not actually convinced. I know that Mr. Woodbury up to quite the close of his life was still sceptical on the subject.—B. & W.

NEW BOOK.

A Book for Bee-keepers. By ALFRED RUSBRIDGE.

IN his introductory remarks Mr. Rusbridge tells us that "at the special request of a wide circle of apiarian acquaintances" he has "endeavoured to give in as concise and simple a manner as possible a few hints relative to the ways and means necessary to keep bees successfully, to get the maximum of pure honey-comb at a minimum of care and attention." We think Mr. Rusbridge has fairly succeeded in his object, and doubt not that all who carry out his suggestions will be rewarded accordingly.

On the principle that "it is a good divine that follows his own instructions," our author takes his pupil to his apiary at once, describes the history and prospects of hive after hive, with an account of the profits actually obtained. There is nothing very new in the bill of fare set before us, but it is good wholesome diet, which cannot fail to agree with all youthful apiarians gifted with perseverance and a sound judgment. "A net profit averaging from 100 to 300 per cent. annually on the capital invested in keeping bees," is temptation enough to set everybody bee-keeping. Good luck, we say, to all who embark in this *El-dorado* enterprise.

OUR LETTER BOX.

DARK BRAHMAS (*R. S.*).—They are very good layers. If you refer to our number published last October 29th, you will see full particulars and woodcuts.

CONFINED SPACE FOR FOWLS (*T. W. B. W.*).—There would only be room for the number of fowls you propose to keep to stand in the space you offer for them. You cannot keep in a house 9 feet by 6 feet more than seven—a cock and six hens, if you desire to keep them healthy. You have no room for a hutch. If, however, you mean to describe the house only, and the fowls are allowed free run, we say you may keep forty in perfect health if they are kept clean, but even then we do not advise you to keep Rabbits in the same place. You may lay it down as a rule, that if the health and well-doing of fowls are concerned they must have a place to themselves, the only exception being where the roof affords the convenience for a loft, which may be devoted to Pigeons, but it must then be ceiled and stopped so that no dirt shall fall through. You would improve your house if you increased the ventilation by having a thorough draught by means of opposite windows that could always be open in warm weather.

BRAHMA'S FEET SWOLLEN (*F. W.*).—You should have told us the age of the cock. If he is an old bird we do not advise any treatment. If he is young the best thing you can do is to confine him where he can walk on soft grass or a litter of hay. The dark blue comb is a serious symptom. It arises probably from disorders consequent on enforced inability to take exercise of any kind. The corns should be soaked in warm water and may then be partially picked off. The hole must be cleaned out, even if it is necessary to enlarge it. It cannot heal while there is a gravel stone in it. The bird must have a table-spoonful of castor oil, and it must be ascertained that it has operated effectually. The effect of this will be to remove the purple colour of the comb. His diet must then be entirely of soft food, ground oats, or slack barley-meal, occasionally some bread and ale. The feet should be poulticed, and each foot wrapped in wash leather. The poultices should be changed daily as long as they seem necessary, and the bird should be compelled to take some exercise by being driven to get on his feet.

CROYDON POULTRY SHOW.—Mr. A. H. Etches was awarded the second prize in the class for Dark Brahma cocks. Mr. R. Wilkinson informs us that his Archangel Pigeons were "highly commended," and not Mr. Cresswell's.

DRIVING BEES (*H. G. M.*).—Drumming is the usual mode of driving bees from full hives, and from empty hives they are generally driven out by one blow or thump on the crown of the hive. You did in the end what should have been done at first, and you succeeded. In the first attempt you drove the bees from the crown of the hive to its side, and there they remained, being unwilling to go further. The bottom hive being "dressed" with syrup was no attraction to the swarm, but the dressing may have hindered the bees from running. Your bees fancied they had run far enough, and their determination to remain where they were has taught you the best and speediest mode of removing bees from one empty hive to another.

SWARM—FIRST OR SECOND? (*B. L. B.*).—We think the swarm you have is the second one from your stock of bees. First swarms weigh from 4 lbs. to 7 lbs. each, seconds from 2 lbs. to 4 lbs. each. The disappearance of the clusters at the door of your hive and the diminished traffic which you noticed were indications that the first swarm had gone. Neither of your hives will be full enough for supering for some weeks. As soon as a hive begins to be overcrowded a single super should be put on it. If your hive had been properly protected from the rays of the sun the combs would not have melted and fallen down.

CRESTED NORWICH CANARY.—Mr. Geo. J. Barnesby is not correct in his description of fig. 92 when he says Messrs. G. & J. Mackley's Crested bird was the bird which took first prize last year at the Crystal Palace Show, first and medal at Darlington. It was a hen, clear with dark crest, that the Messrs. Mackley bought at the Norwich Show, and only awarded fourth there, which afterward took first and medal at Darlington, not the cock. Nor did it take first or second at Yarmouth or Lowestoft as stated.—W. B. HOVELL, *Norwich*.

YOUNG THRUSHES CRAMPED (*H. D. C.*).—It is not an uncommon occurrence for Thrushes or Blackbirds either to be afflicted with cramp in their claws when brought up in cages where water vessels are continually kept inside. Young birds especially are more liable than those of mature age. The continual paddling about in the damp paralyses their feet and brings on a kind of rheumatism. If you have used a water vessel inside the cage, remove it to the outside so that the birds may have access to it. If the powerless state of their legs prevents them reaching the water vessel, supply the birds for a time (until they gain strength in their legs) with the food somewhat moist. Give the birds barley-meal moistened with milk alternately with soaked bread, worms and scraped beef occasionally. Each day for a week at least hold or immerse the bird's claws and legs in warm salt and water (not too warm) for three or four minutes each time, and after taking them out gently rub their shanks and claws with brandy in which a pinch of cayenne pepper has been put. Lower the perches in the cage to within 2 inches of the floor of the cage, over which should be strewed soft hay or dry moss. Keep the birds dry and warm whilst so powerless in their feet. Thrushes are very fond of bathing, and a bath is very essential, but it should be supplied so that the cage bottom should not remain damp for some considerable time afterwards. One plan is to attach a small cage—a kind of ante-chamber—containing the bath, hooked on before the opening or doorway, and when the bird or birds have bathed remove it.

REMARKS.

2nd.—Rather cloudy early, but soon clearing off gave us a most beautiful day and night.

3rd.—Another very fine day, but rather too warm and close to be pleasant; thunder at a distance all the afternoon.

4th.—Fine early and much cooler; fair all day, but rather stormlike in the afternoon, and cloudy at night.

5th.—A very fine day, and very pleasant from there being a cool breeze all day.

6th.—Very slight rain early, but soon cleared, and was fair all day, though a little cloudy between 8 and 9 P.M., and windy at midnight.

7th.—Not a pleasant day, being cloudy and very windy; stormlike in the afternoon and evening.

8th.—Bright and fine all day, and at times very warm.

A fine warm week.—G. J. SYMONS.

COVENT GARDEN MARKET.—JUNE 9.

A LARGE supply of outdoor produce has arrived in the market during the week, and the supply from under glass has also much improved both in quality and quantity, the only scarcity at all felt being in first-class Peaches. Considerable stocks of new Potatoes are now on hand from the Channel Islands, Malta, and Lisbon, at rates ranging from 12s. to 18s. per cwt.; and good old Potatoes can easily be obtained.

From observations taken near London during forty-three years, the average day temperature of the week is 72.7°; and its night temperatu e 48 8°.

CHOICE SPRING FLOWERS.

SPRING flowers have been treated upon in the Journal so often and so well that the subject might not unreasonably be considered exhausted. There is, however, an important class of plants which by some strange inadvertence have hitherto remained comparatively unnoticed — I mean dwarf flowering shrubs, which for their low compact growth and great intrinsic beauty certainly merit the best attention and care, and a much more prominent position than has yet been given them.

Take, for example, the Sun Rose (Helianthemum), what can be more beautiful? and yet how seldom is it met with? It comes readily from seed, and the seedlings of both sections soon grow to a considerable size—those of stiff erect habit forming compact bushes about 3 feet high and as much through, bearing a profusion of flowers in May and June of various shades of pink, purple, yellow, and white; and the more dwarf section forming dense spreading cushions of about a foot high, also flowering in May and June, the colours ranging through a variety of shades, such as pale primrose, bright yellow, rich orange, deep rose, crimson, pink, and white. They are as suitable for vases, beds, and borders as for rockwork, upon which they are usually found.

Andromeda floribunda is another valuable shrub of dwarf spreading habit, better known, perhaps, than the Helianthemums, but which, like them, is not cultivated so extensively as it ought to be. It is true that a solitary plant of it may occasionally be seen in the fringe of Rhododendron beds, or a few pot plants in early forcing houses; but the fine effect of large masses of the pretty Heath-like blossom, which it puts forth in April, does not yet appear to be understood. A. Catesbœi, which comes into flower about a month later than floribunda, is of a somewhat more straggling habit of growth; it is a distinct and beautiful species. The foliage and bark of the young growth are of a deep red colour. The full beauty of the panicles of white flowers often remains unnoticed, especially upon young plants, as the flowers cluster so thickly and heavily upon the tips of the flexile shoots as to bend them down almost to the ground.

The Pernettyas put forth their flowers almost simultaneously with the Andromedas; the narrow-leaved kind, P. angustifolia, is an interesting and ornamental plant, growing about 2 feet high, bearing a profusion of spikes of minute white flower bells; in May and June and afterwards having pretty clusters of crimson berries, which remain in charming contrast to the evergreen foliage for several months; thus taking as high a rank among berry-bearing plants in autumn and winter as it does among flowering shrubs in spring. P. mucronata is a much bolder variety, having comparatively large foliage, and reaching a height of 5 or 6 feet. It is a handsome shrub.

Spiræa Thunbergii is one of the brightest gems of April and the early part of May; it is a dwarf variety, the slight flexile growth, clothed with soft feathery foliage and springing directly upwards from the crown, does not attain a greater height than 2 feet. It has a graceful appearance, and when in flower it is so crowded with pretty white blossom that the shoots bend over each other in the most charming manner, and are then literally such wreaths as we covet for our bright May garlands. There are other early-flowering species of this lovely and extensive genera, such as the pink kinds Nobleana and lævigata, and the white ariæfolia; but none of them to my mind are at all to be compared either for beauty or utility with my favourite Thunbergii.

Daphne cneorum, sweetest of all the Daphnes, is an old and general favourite of such great excellence that it must not be omitted here. Growing luxuriantly in exposed situations it yields a profusion of its deep pink richly-scented flowers in April, and it also forms a charming feature in the early-forcing house in pots, bearing forcing well, but with the flowers of a paler hue than when seen in the open air.

Azalea amœna, the rosy-purple Chinese Azalea, is very beautiful when laden with its cheerful flowers in May. It is a distinct and most interesting species—just one of those gems that are worthy of a place in every garden.

Kalmia glauca is another interesting little shrub, forming compact bushes of about 2 feet high that are bright from April to June with pretty flowers of a deep purplish-red hue. Its minute growth and abundant blossom render it a very suitable plant to occupy many an odd nook and corner in rockeries and shrubbery borders, as well as to form a fringe to kindred plants of more lofty growth.

Mixed beds of shrubs of the kinds I have selected and some others have proved so interesting and ornamental as to induce me to append a note descriptive of the most effective method of arrangement. Taking a circular bed of, say, 20 feet in diameter, I would devote the centre chiefly to Rhododendrons, leaving a border 4 feet wide for the mixed shrubs. Among the Rhododendrons there should be some Tritomas, Liliums, Gladioli, and the yellow Œnothera gigantea to brighten the centre with their gay flowers after the shrub flowers have faded. In the border the dwarf kinds of Sun Rose would find a place near the edge with Daphne cneorum; the taller varieties standing back among such plants as Berberis dulcis and B. stenophylla, the Kalmias glauca, angustifolia, and nana, Erica mediterranea, the Pernettyas, Spiræas, Skimmias, Erica carnea, and Gaultherias, all being blended together and placed according to their respective heights, interspersed with a few select kinds of Iris, Solomon's Seal, clumps of Anemone coronaria and Lily of the Valley, with such spring bulbs and choice perennial plants as taste or fancy may suggest.

Cut the bed in halves, and you have an arrangement of the best kind for a projecting sweep, or in fact any part of a shrubbery border. The materials are choice, perfectly hardy, of easy culture, and the novelty of the arrangement, differing as it does from the stereotyped and

somewhat monotonous repetition of more common sorts of shrubs, is precisely that which will probably tend most of all to commend it to my readers.—Edward Luckhurst.

GROS GUILLAUME GRAPE.

Mr. Luckhurst has done good service in drawing attention to this valuable late Grape, but I cannot agree with him, nor with "A Northern Gardener," or the author of the "Fruit Manual" in its being a shy bearer. "Pruned," says "A Northern Gardener," "on the orthodox spur system and with only ordinary heat it will seldom be satisfactory." Mr. Luckhurst is so rapturous as to exclaim, "Oh for an entire house of Gros Guillaume upon its own roots which could ramble unchecked and free in a wide border of sound rich soil!" In the "entire house" I cordially agree with him, not because it is a shy-fruiting sort in limited space nor when spur-pruned, but because it ripens a month later than any other Grape, swelling and colouring perfectly, though the ripening process be deferred until late in September or October. I am also thoroughly convinced that grafting to induce fruitfulness is altogether unnecessary. I have by force of circumstances but little space to do a great deal with, but small means may be as effective for a purpose as great. A miniature Apple tree may give as fine a fruit of its kind as one forty times the size, and a Vine in a ground vinery or in a small house with a very limited extent of foliage surface, a result corresponding in proportion to one with a large house to itself. A given extent of surface-foliage, that surface will only give a certain amount in weight of Grapes. It is vain to expect a Gros Guillaume, Syrian, White Nice, and other large-bunched Grapes to give as many bunches in a given space as a White Frontignan, though they will give an equal weight of Grapes from a similar extent of surface, which means that Gros Guillaume requires for the production of a bunch of 6 lbs. weight an extent of surface capable of producing six bunches of any other kind of 1 lb. weight each.

It has been stated by one of our best cultivators of Grapes that 1 lb. per foot of rafter occupied is a very fair average of the producing power of Vines, and as the Vines are planted at various distances apart the approximation appears to have no fixedness. Three feet and even less, and all distances up to 4 feet 6 inches and more, have I seen the rafters and the Vines apart; so that 3 square feet or 4½ (half as much more), or 5 or 6 square feet are equal to the production of a pound weight of Grapes. It follows that those with fine vineries, the Vines at 4 to 5 feet or more apart, can obtain 2 lbs. weight for every foot of rafter occupied; whilst those who are so unfortunate as to have the Vines 3 feet apart can only produce a pound. Poor unfortunates! For doing with Vines at 3 feet apart what others do with theirs at 6 feet, obtaining the same amount of weight in Grapes, you are considered Simons. Your bunches only weigh a pound, while the others weigh two. Do not suppose that the cultivator who grows the 2-lb. bunch is twice as clever as the other, and do not expect of having 1 lb. per foot of rafter if they are 18 inches apart, which is putting the case the other way; and if you fancy to have in place of twenty bunches of a pound weight on 20 feet of rod the same number of bunches weighing 4 lbs. each, the surface being the same, you are certain it may not be the first time of disappointment, but of overcrop and its many attendant evils present and prospective.

Three square feet of surface, I think, are required for the production, in perfection, of a pound weight of Grapes, irrespective of kind or other consideration, be it grafting or what it may, the conditions of cultivation being in other respects favourable and suited to the kind. Small-bunched kinds will give more bunches than a large-bunching kind, and though the number of bunches may be very dissimilar, the quantity by weight is not materially different. It applies equally to Vines of the same kind as to different varieties. Large bunches are not to be had in the same number as smaller from a given quantity of surface; but as the bunches are large or small according to the vigour or stoutness of the wood producing them, it follows the distance the spurs are upon the rod the bunches will be large or small in proportion to the distance, or rather space, each spur-shoot is provided with. There is of course a limit to the productive power (though Mr. Hunter's doings with Black Hamburgh tend to show the contrary) of even the "extension system," little being gained by pushing the extension too far. Nothing may be lost in quality; but the greatest produce, quality also considered, cannot be said to be attained by extended surface unless it be increasingly productive.

Monster bunches are not, though we admire them and applaud the growers, the acme to aim at in Grape cultivation, for they are as a rule had at the expense of quality. The great aim of the cultivator is to obtain the maximum of quantity and quality from given means, the two being inseparable. It is rare that large bunches combine quality with usefulness; their value is not so great for table or market as fair-sized bunches, though it may require two or three of them to weigh as much. In the market a 2-lb. bunch of Hamburghs will fetch as much as one of 4 lbs., the former being of superior quality and the other deficient in colour—wanting the characteristic of quality. The offering of prizes for the largest bunches is only encouraging bulk and coarseness. It ought to be an instruction, when such prizes are offered, that mere weight without the fullest satisfaction as to quality is not to prevail.

But after this digression I come to the small house at last. It is a low lean-to—half a foot of wall above ground, and 3 feet of glass in front, 11 feet high at the back, and 12 feet wide. The house is planted as follows:—3 feet apart two Black Hamburghs, one Black Muscat, three Lady Downe's, two Gros Guillaume, one Mrs. Pince, one Muscat of Alexandria, one Black Hamburgh, and one Muscat of Alexandria—as motley an arrangement as could be wished. The Vines are not started at all, but are allowed to break naturally, having no fire heat except to exclude frost or dry up damp from November to May, a minimum of 40° to 45° being maintained, free ventilation given by day; and to disperse damp, fire heat is given by day and withdrawn at noon, so that the heating medium is cooled down by night, a little air being left on all night all the time the Grapes are hanging. Until the shoots are stopped beyond the fire heat above-named they have none, but then we raise the temperature to 60° at night, and 65° when they are in flower, keeping the temperature 65° to 70° by day in dull weather, admitting air when sun heat raises the temperature to 75°, not exceeding 85° without full air, and this is maintained until the fruit is all ripe, except Gros Guillaume, and the temperature is lowered 5° in the course of a fortnight, and 10° in a month, when we are careful only to exclude frost and damp. The Hamburghs are ripe in August, fit to cut early in September, and they are good up to Christmas. Black Muscat of Alexandria follows in a few days, and they are in good condition at the end of February. Muscat of Alexandria comes next, they are fair up to Christmas; Lady Downe's and Mrs. Pince ripens together, and Gros Guillaume a month later than those. The house was filled with bedding Geraniums in November; all the leaves being picked off, and potted in moist soil they did not want any water or lived without until the Hamburghs and Muscat of Alexandria were cut, Mrs. Pince, Lady Downe's, Gros Guillaume, and Black Muscat not caring about a little moisture in the atmosphere so long as it is not stagnant, and can escape by the ventilators. It is a close, still, moist air that is fatal to ripe Grapes.

On the 18th January all were cut, in fact the Vines were pruned and the Grapes removed to a fruit room, the ends of the shoots inserted in bottles of water, one sort of bottle being as good as another, and those we had contained about a pint of water and bits of charcoal about a walnut size altogether to each bottle. They cut sound, the last cut April 19th.

The productive power taken in order of planting as before stated is indicated by the bunches borne by each Vine—viz., 16, 20, 20, 24, 22, 20, 17, 8, 18, 18, 18, and 20. Lady Downe's had the greatest number of bunches, and Gros Guillaume the least, 17 and 8 respectively. The Vine with the seventeen bunches did not have so good a crop as the one with eight, for one bunch was worth any four of the other, and I find it gives fully more than a fourth greater weight of Grapes than any of the other Vines. It has never missed a crop in six years, and I cannot therefore admit the Gros Guillaume a shy bearer. Of course I shall be laughed at, but I am quite proof against sneers. There is no doubt that many have such small houses, and would have Grapes in them, only they are debarred from its being represented that late Grapes require noble structures to grow them in, which they have not and cannot afford.

It is foreign to my purpose to run down longer, wider, loftier houses—they are every way deserving of leading; at the same time let us not forget that by making those the standpoint we are shutting out from a participation in the luxury of Grapes a vast majority of horticultural devotees, who grow not Grapes so much for their own use as that they may have to give to the sick, Grapes (especially late) being a luxury to invalids. Many grow flowers and fruits that they may gladden other hearts by

example, and instil into other minds a taste for the beautiful and good. Long may they prosper.

I ought to have said that the crop given as that of last year is too great for a year-to-year crop. The crop on Vines with the rafters named—13 feet 6 inches, ought not to exceed thirteen bunches for Black Hamburgh, Mrs. Pince, Black Muscat, and Muscat of Alexandria; six to eight should be the extreme for Gros Guillaume, whilst Lady Downe's will carry eighteen as well as the other do their respective number. The crop last year was for a purpose I need not here explain, and though high feeding may help with an overcrop it is not commendable.—G. Abbey.

SALVIAS FOR WINTER DECORATION.

The thought has often occurred to my mind that there is some analogy between a cook and a gardener; with the cook no sooner is one meal prepared and dispatched than another has to be thought about, and such is the routine of a gardener's life. If we have necessaries for the table and season, and plants in perfection and fit for any purpose of decoration, even this does not tell us that we may rest and be thankful. Our motto must be "Onward," and the present time demands much at our hands, for not the head at work alone will suffice, the hands must be diligent to keep abreast of pressing work.

We have feasted our eyes on the beauty of many plants during the last few months, but their mission is over for this season, and we must now turn our attention to providing others for another period of bloom.

When the days are bright and sunny, and the earth is mantled with beautiful flowers and foliage, we are apt to forget that the dreary days of winter will overtake us, but let us be on the alert and be prepared to meet those dark days with bright flowers suitable for the season. For that purpose we must now turn our attention to the Salvias, for they are very cheery flowers for the dull months of autumn and spring, for which purpose S. gesneræflora is invaluable; but S. splendens also claims our attention and is equally valuable, and being the earliest bloomer must first engage our attention. This variety after flowering is by many cut down and grown on for another year, and, perhaps, without repotting. This is a practice we never follow, for we propagate annually by striking cuttings now, or a little earlier is better; but even now good portable plants can be grown fit for most ordinary purposes. We seldom grow them in larger than 9-inch pots. A warm greenhouse, or what is called a cold pit, at this time of the year will be a suitable place to grow them in. Good loam, leaf soil, or well-rotted manure, and a little sharp sand with ordinary care will grow them well.

We hope the practice of riddling potting soil is becoming extinct; in most cases of plant-growing good drainage is essential, and also clean pots. It is not always necessary that a pot should be washed every time it is used, but the inside ought to be well rubbed-out; it must also be perfectly dry. I have heard people remark, What is the good of having a clean pot to put soil in again? Why does a workman prefer a clean bright tool to a dirty one? Simply because it is much easier to work, and the work is much better done. If anyone is dubious about this let them use a dirty pot with soil and roots adhering to its sides; let the pot be wetted before it is used, taking care not to let it dry before the soil is put in, and have the soil as dry as possible, and whenever it is thought that the roots of this potted plant have reached the sides then turn it out. If the operation has been properly carried out the result will be, the newly-made roots will have taken hold of the sides of the pot and the old soil, and, as a matter of course, the plant will be robbed of its newly-formed roots. Whereas if the pot is clean and the soil not too wet the plant and soil will turn out as clean as a sponge-cake out of the mould of a pastrycook.

As the plants advance in growth they will require frequent pinchings so as to keep them bushy. It must, however, be borne in mind that the longer they are pinched the later will they bloom, so that they ought not to be pinched later than July. S. splendens if grown in too dry a heat is liable to be attacked with red spider, for which the best remedy is the syringe night and morning. This variety will bloom well in the autumn months, lasting well up to Christmas. It will bloom better and last longer in an intermediate or a warm greenhouse. After the flowers have fallen its scarlet calyx will last a long time in beauty. S. gesneræflora succeeds splendens and blooms in the spring months. At all times during the growing season keep them as near the glass as possible, so as to prevent weakly-drawn shoots.

Plants which are already struck may also be planted-out now to be potted-up in the autumn. By this means we have had huge healthy pyramids which in spring have been very effective. S. Heerii is very similar to S. gesneræflora, but is, perhaps, dwarfer in habit; it is very useful for spring decoration. The old S. fulgens if potted will afford a continuation of its rich scarlet blooms until December, when S. splendens and S. gesneræflora will continue the succession until March. That is a period when scarlet flowers are in great request, and I know no class of plants which will give them more easily and certainly than the winter-blooming Salvias.—G. R. Allis.

VARIEGATED KALE.

Now that Beet is permissible in the flower garden in summer, surely the variegated Kale may have a place in the borders in winter. That there is a certain amount of prejudice against admitting vegetables in the parterres is certain, but it has not been sufficient to keep out the Beet even when flowers and fine-foliaged plants are abundant; therefore it should not keep out the Kales at a time when we have scarcely anything to add a ray of cheerfulness to our gardens at the dull period of the year. But prejudice cannot say the Kales are coarse, for no more elegant foliage can be found than is afforded by the fimbriated varieties; neither can they be asserted to be dull and colourless, for they range from pure white to pink, purple, and crimson. They are also hardy. Herein they possess a trio of qualities in a degree which no other plants possess during the very dullest period of the year. When other plants fail these assert their power to attract, and they preserve their attractiveness just so long and no longer than the time at which spring decorative plants unfold their charms. Thus they are emphatically winter plants, and it is on that rare quality which mainly rest their claims to culture.

It is fair, however, to presume that very often Kales are condemned without a fair trial, for it is seldom that when a superior strain is examined that the plants not only escape the penalty of threatened expurgation, but they receive the reward of appreciative praise. It is undeniable that great disappointment is felt at the result of plants which have been raised by purchased seed. In the first place, a length of time must elapse before the plants show any variegation at all, and when the variegated character is assumed it is only worthy of notice in about one plant in twenty, the rest being miserable apologies for variegated plants. This arises from the extreme sportive nature of the plants, and it is only by very special care that anything like a pure stock can be preserved by seed.

In order to have attractive plants in the autumn it is necessary to plant out extensively in the spring, so as to have a considerable number to select from, and the probability is that a choice may be made of plants both attractive in form and brilliant in colours which are well worthy of a place in the flower bed or border. To raise plants for ordinary flower-garden purposes the seed should not be sown early in spring, or the plants will be tall, coarse, and unwieldy by their long season of growth. Small compact plants are generally far preferable, and such may be had by sowing seed early in June.

In transplanting for summer growth it is necessary that the site be very exposed, and the plants be set out thinly. If planted close, in a sheltered place, they become drawn and the bottom foliage is quite spoiled. They do not show their variegation until late in the autumn, and just at the time when colour in most other plants vanishes. That is why they are valuable; and if the colours are nicely mixed a bed will be infinitely more inviting when planted with these gay Kales than it was a fortnight before by the waning bedding plants.

I have seen beds and plants of Kale in December, January, and February elicit the warmest approbation from all who have seen them, and win the praise of those accustomed to enjoy the best and brightest flowers which could be produced. Except when snow is on the ground these Kales are always attractive during the winter months. They should be planted in November sufficiently deep that the leaves rest on the ground, and the contrast with the milk-white foliage of some and the dark soil, and relieved by purple, pink, and crimson, will certainly be as attractive as any other plants in the garden. They should remain until nearly in flower, and the very best can then be removed and planted together to perfect seed. I

have frequently removed plants when in full bloom, and planted them under a north wall, where they have ripened seed perfectly.—A Surrey Gardener.

ANOTHER REQUIREMENT OF THE ROSE.

At a time when so much is said in favour of the Rose and its manifold points of beauty it may appear presumptuous in one who, like myself, has taken no share in the discussion to mention one further requirement in at least one class of Roses that does not seem to have struck the minds of those who have given us so much information on the other good qualities of the respective varieties. This may arise from the fact that they may disavow the object which I and others have in view, or it is possible condemn it altogether. But I am unwilling to believe that they will do the latter; and being also aware that my case is one of a great many, possibly outnumbering all the exhibitors put together, I at once put forth my notion of what a Rose ought to be to meet such requirements as is expected of it here and in a great many other private places where this popular flower is grown.

To come to the point, I may say that we are in the habit of cutting Roses to send away by the bushel, and most other private places where the family are not at home at the time of the Rose season expect this to be done, and who can say they have not a perfect right to do so? and who can begrudge a bunch of Roses being sent anywhere rather than allowed to waste on the tree? But there is one thing above all others I do begrudge, and that is the necessity there is sometimes of cutting several backward buds along with the bud that is just advanced to the required stage for cutting. It is this needless waste that I would like to see avoided, and some Roses have the good property of furnishing good long stalks to each individual flower, whereby they can be cut and bunched without any loss. Now, it is not, perhaps, asking too much if it were said that there are many who would be glad to have a list of the kinds that produce fairly good flowers in this way, and especially if they also are "abundant bearers." It is all very well to describe a good Rose by seeing it in a winning stand at some show, as its appearance there is improved by having a number of buds on the same shoot, but the stern economist would like all and each of these buds to do their duty by themselves: hence the advantage of having Roses on single footstalks. Of course where two or more are all advanced alike it is even better than when singly; but as this is so seldom the case, either the one is allowed to expand too much, or the others are cut too soon, and a waste takes place which is always a source of regret. As the respective merits of Roses seem now very closely canvassed, might not a class meeting the requirements of a vast number of growers have a share of consideration?

Roses for bouquets, stands, and the like form a more extensive class than for mere exhibition purposes; and though, doubtless, many kinds will serve both, the favour shown to the one so far transcends what the other has received that it is not without some shadow of justice on my side that I plead the cause of the one that does all the hard work, and would ask censors in passing an adverse opinion on a new or old variety to pause and inquire if it will suit the grower who has his flowers all to cut. Moreover, it would also be well to ask if it produces its buds in good quantities, and each one of fair average quality. A solitary grand bloom now and then will not do for the grower for market, neither for the private grower whose flowers have to be sent to London or elsewhere, however much they may suit the exhibitor.

It will be seen by the above that I am by no means insensible to the merits of a Rose for exhibition purposes; but I would certainly not admit that to be the only use this queen of flowers is intended for: on the contrary, judged by the all-important standard of utility, exhibition is only a secondary purpose it is applied to. If growers, or rather vendors of new varieties, would now and then put in a remark or two bearing on the qualities of the kind recommended for the everyday purpose it is expected to assume, much good service would be done. I am not sure but another standard of excellence differing widely from that put forth by florists in general might be required by those who cut their flowers by basketfuls. Most of us would like a stiffer stem than many of the Teas possess—say, for instance, Maréchal Niel, which carries his head in anything but military fashion, implying a rebuke on the raiser selecting such a name. A Rose of less imposing importance, supported by a firm stiff stalk that would retain its position when stuck by some dainty hand in a drawing-room vase or stand, would suit the wants of everyday requirements much better, lovely as the Marshal is pronounced to be.

Roses encased in a square or oblong box, and surrounded by gazing crowds of sightseers, doubtless has its advantages; but there seems no reason why that should usurp the only purpose to which the flowers are applicable, and as other uses offer themselves let them be turned to the best account, and the careful collector of cut Roses would be grateful to those who would increase the number of varieties producing fair good flowers in the half-expanded condition on single stalks sufficiently long for the purpose wanted. We are often pained by being obliged to cut others in a backward state with the one flower wanted, and a waste is the consequence. This matter is of more importance than may at first sight appear to be the case, and I submit it to our Rose-growing friends as one deserving their attention not less than the fragrance of respective kinds.—J. Robson.

LATE APPLES.

Good-keeping Apples are the most useful of fruits. A store which lasts in good condition month after month in the spring and summer period of the year is a store of great value. This is the period of the year to test the relative value of varieties. If they keep until now in a fresh crisp state they are worthy of honourable mention, even as much so—dare I write it—as are sweet-scented Roses. Which are really the best late sorts? I mean those which bear well and keep well without any special care. It would be interesting, and particularly useful, if those having, or have had until recently, sound Apples, would let us know their names and a sketch of the conditions under which they have been preserved. Mere size is not so much an object, neither is a very high standard of quality to go for too much at this season. Free-bearing, late-keeping, good, useful Apples are the kinds of which I think information would be acceptable. There is no difficulty in having Apples in the winter, but we want them now, and until Apples come again. What are the best for culinary purposes, and the best for dessert? I, for one, should be glad to know, and I feel sure the information would be generally acceptable. Three Apples which I have for a number of years found the most valuable are Sturmer Pippin, dessert, small, free bearer, and keeps fresh in a dark and not too dry cellar throughout June; Striped Beefing, large, sunny side red, a good bearer, and sound until June; Gooseberry Apple, medium-sized, great bearer, very firm throughout June, and often useable until August. What is the experience of others with these and other sorts?—Pyrus Malus.

PRIZES FOR AMERICAN POTATOES.

In consequence of our offering various silver cups and other prizes for American Potatoes this season, an inquiry has arisen amongst intending competitors as to which sorts of the great number of varieties in cultivation were of American origin. In order, therefore, that no confusion may exist upon this point, and that no exhibitor may be disqualified by the presentation of sorts not American, we ask you to publish for us the undernoted list of Potatoes which have been introduced to this country from America.

Alpha,	Extra Early Vermont,	Bresee's Peerless,
Eureka,	Compton's Surprise,	Bresee's Prolific,
Snowflake,	Early Gem,	Early Goodrich,
Brownell's Beauty,	Late Rose,	Garnet Chili,
syn. Vermont Beauty,	King of the Earlies,	Peachblow,
	Climax,	Early Rose.

The above list stands about in order of date of introduction, the newest varieties being first.—Hooper & Co., *Covent Garden.*

Messrs. Veitch & Sons' Fruit Prizes.—These will be competed for on the 21st of July next in the garden of the Royal Horticultural Society. The schedule has already appeared in our advertising columns, and amounts to the munificent sum of £111 to be distributed in money. This liberal encouragement of fruit-culture on the part of Messrs. Veitch at a time when the national Society is so sadly crippled is very opportune; and when we see this repeated year after year we hope that the Messrs. Veitch will in return receive the support they deserve by the extent and quality of the exhibition, to which many look forward to now as one of the events in the horticultural year.

The entries are to be made as usual at the Royal Horticultural Society, South Kensington.

ROYAL HORTICULTURAL SOCIETY.

JUNE 16TH.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. William Stannard, gardener to H. C. Roberts, Esq., Cecil Lodge, Abbott's Langley, sent a dish of Strawberries which was exhibited under the name of Dr. Hogg, but which proved on examination to be mixed varieties. Thomas Laxton, Esq., Stamford, sent two dishes of Pioneer Strawberry, large, and fruit varying from conical to cockscomb shape, bright red colour, with small seeds slightly depressed. The flavour was brisk and good, but the Committee did not consider it worthy of a certificate. Mr. Laxton also exhibited a very fine dish of Dr. Hogg Peas quite filled, and which were sown on the 18th of March.

FLORAL COMMITTEE.—Dr. Denny in the chair. Messrs. J. Veitch & Sons of Chelsea had first-class certificates for Adiantum Hendersonii, a very distinct species; the fronds have erect footstalks, and arch over gracefully. Begonia Emperor, a very fine hybrid of the B. Boliviensis and Pearcei type. The flowers are a bright orange-scarlet, larger and of a better shape than any of its predecessors. The same firm showed Dracæna Taylori, with magnificent bronzy metallic foliage; it is a garden hybrid between D. magnifica and D. Mooreana; D. elegantissima has very neat erect-growing bronzy leaves, edged with crimson. They also exhibited for the approval of the Committee a very fine new Fern from Columbia, Asplenium ferulaceum. The plant was in too young a state to adjudicate upon, but when the sori is developed it will no doubt have the highest award. The pinnæ are finely divided, and the fronds very beautiful.

Messrs. Cripps of Tunbridge Wells sent Clematis Grand Duchess, a splendid variety, with flowers about 9 inches across, blush white and of good quality; it received a first-class certificate. C. Leviathan, a double flower, was exhibited with it. They also sent a box of flowers of C. excelsior, a fine double variety. A collection of double-flowered Zonal Pelargoniums was sent by Mr. Thomas Laxton of Stamford. Six varieties had white flowers; all of them are advances on Aline Sisley. Wilfrid is certainly the best, and well deserved the first-class award voted to it; Guiding Star is a very distinct flower of the scarlet section. From Mr. Perkins of Leamington was sent Pteris serrulata cristata and Scolopendrium vulgare aurea variegata, the latter blotched with yellow; also Lilium Thunbergianum flore-pleno. Scutellaria mocciniana, from the Society's Gardens, is a useful decorative flower, bright scarlet, with an orange lip. Messrs. Carter & Co. received a vote of thanks for Coleus Mandarin, a variety like C. Bausei. Mr. Laxton also sent a fine creamy-yellow Tea Rose, Lady Isabel Cecil; it has good strong foliage, and looks promising. H.P. Vivid is a dark flower resembling Charles Lefebvre.

A vote of thanks was given to Mr. R. Dean, Ealing, for cut flowers of a fine strain of Canterbury Bells. A plant of Primula scotica was referred to the Scientific Committee. A new Lobelia having bright blue flowers with white centre; and a new black Fansy Othello was of good shape and free-floweriog, both from Mr. Dean. Cut flowers of a perpetual-flowering Picotee Minnie sent from Mr. John Wiltshire, Beaconsfield, Bucks, were too late for the Committee. Mr. C. Ross, gardener to C. Eyre, Esq., Welford, Newbury, sent a cut truss of Crinum amabilis.

WARNING! NEW POTATO DISEASE.

WE regret to announce the appearance of a new Potato disease more disastrous in its effects by far than that from which the plant has suffered during the past thirty years. It is a fungus which attacks the plant when not more than 6 inches high: the seed tuber prematurely decays and becomes a mass of rottenness, the young tubers are consequently arrested in their growth, and the haulm withers and decays. The discovery has only just been made, and the disease is being investigated by the Rev. M. J. Berkeley, who discovered it in the gardens of the Royal Horticultural Society at Chiswick. It is remarkable that the disease is confined to the American varieties.

THE FORTHCOMING EXHIBITION AT THE LOWER GROUNDS, ASTON, BIRMINGHAM.

PRIZES of considerable value are offered for everything likely to be worth exhibiting on the 1st of July. For sixteen stove and greenhouse plants in bloom the prizes are £25, £18, and £12, with a challenge cup value twenty-five guineas to the winner of the first prize. For ten stove and greenhouse plants in bloom are one class for the trade and one for amateurs, the prizes in each being £12, £9, and £6. Good prizes are offered for specimen stove plants and greenhouse plants almost of every class, and collections of every class of Pelargoniums. The prizes for cut Roses amount to about £250 in money, and two silver challenge cups, each worth twenty-five guineas. For other cut flowers, vegetables, and fruits, the prizes are on an equally liberal scale. Such prizes will no doubt draw together a magnificent display.

The object to which the profits of the Exhibition are to be devoted is so admirable and so warmly supported in Birmingham and the midland counties generally that we hope the horticulturists of Great Britain will combine to ensure an Exhibition responding to the enthusiasm which will secure the presence of enormous masses of spectators at the Lower Grounds on the 1st, 2nd, 3rd, and 5th of the coming month. Mr. Quilter has generously provided all necessary funds for the Show, and on him all the risks depend. The beautiful grounds, now in a state of great beauty, will be devoted to the interests of the Midland Institute.

This Institute is an educational establishment where artisans and others, male and female, are enabled to continue their education after leaving school and entering on the work of life. The first stone of the building was laid by H.R.H. the late Prince Consort on the 22nd November, 1855, on a site of much value given by the Corporation of Birmingham. On the building, the furniture and apparatus used in the science classes, &c., a sum of about £18,000 was expended. Commencing with 165 students in the first year of the Institute's existence, the number in 1874 was 2179. Such a large increase was greater than the most sanguine expectations of the founders led them to expect. Large as the building is, it is totally inadequate to the present requirements, and as every year the applicants for admission increase in numbers, it has long been felt that additional buildings must be erected in order to accommodate the growing body of students. With this end in view a contiguous site has been bought for the sum of £14,000, and the erection of the new buildings is to be set about at once. Their estimated cost is £16,000. Of this total sum of £30,000, £22,000 has already been raised. A sum of £8000 is still wanted, and the profits of the forthcoming Exhibition will be handed over to the Committee as part of it.

Nor must it be forgotten, as a very strong claim upon the gardening community, how liberally the people of Birmingham gave their money to horticulture when in 1872 the Royal Horticultural Society held its provincial Show at the Lower Grounds—a Show which was more profitable to the Society than any other held by it in the provinces.

The Show will open on Thuredsy July 1, and will remain open till the evening of the Monday following. The period for making entries has been extended until Thursday the 24th inst. We sincerely hope we may have the pleasure of recording that the entries are worthy of the occasion.

ROYAL BOTANIC SOCIETY.

JUNE 16TH.

BENEATH lowering clouds, threatening rain, was the second summer Exhibition at Regent's Park held; the day, however, was, notwithstanding a shower or two, agreeable to visitors, and at the least equally so must have been the display arranged for their approval and gratification.

The bold banks of stove and greenhouse plants were the most striking feature of the Show, in some of the classes for which there was good competition. For twelve plants (open), Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, set up a group in the style of excellence in which Mr. Wilkins' plants are characterised. The most noticeable were a splendid globular plant of Erica Cavendishii quite 6 feet in diameter, and not a failing place in it; E. tricolor impressa, 4 feet across, a model of good culture; a striking Kalosanthes with more than a hundred heads of bloom; excellent Aphelexes; a Clerodendron, Bougainvillea, Hedaroma, &c. Mr. Carr, gardener to P. Hinds, Esq., Weybridge, exhibited nicely grown smaller specimens. Mr. Wheeler, gardener to Sir F. Goldsmid, staged a group made gay by four immense and well-bloomed Azaleas 6 feet high.

In the class for six stove and greenhouse plants (amateurs), Mr. Ward was to the front again with a really good group—Ixora Williamsii, Ericas, an Aphelexis and Stephanotis showing prominently. Mr. Donald, gardener to J. G. Barclay, Esq, Leyton, staged also a grand lot, and is evidently a competitor not to be played with; his Rhyncospermum, Azalea Chelsoni, and Phœnocoma were admirably grown. Mr. Toms had a nice but a more irregularly grown group.

In the corresponding nurserymen's class Mr. Williams set up a huge Genetyllis 6 feet in diameter; Anthurium Scherzerianum with thirty spathes; Allamanda grandiflora, bright clear yellow and very effective; a Dipladenia, Aphelexis, and Dracophyllum.

Mr. Morse, Epsom, staged also large, compact, and healthy plants, a Rhyucospermum and Clerodendron being very good. Messrs. Jackson & Sons had a superior group, Azalea Duchesse de Nassau and a Bougainvillea being the most noticeable.

In the Heath classes were some very fine plants, but several also somewhat loose. For six plants (amateurs) Mr. Ward staged plants not large, but bearing the impress of good culture. Mr. Wheeler's plants varying in size and merit, but not calling for special comment. In the corresponding (nurserymen's) class Messrs. Jackson & Sons, Kingston, had an irregular but well-bloomed collection, E. Nelsonii being fully 6 feet over. Mr. Morse, Epsom, also exhibited a collection which contained some well-grown specimens. In the class for nine plants (open), Messrs. Jackson & Sons, Kingston, again staged large but rather loose plants, yet fairly good; Mr. Wheeler also competing with a very nice group of considerable merit.

In the classes for Ferns many good plants were exhibited. In the amateurs' class for six Mr. Donald, gardener to G. P. Barclay, Esq., Leyton, had the largest plants. Mr. Ritchie, gardener to R. H. Prance, Esq, Hampstead, staged excellently grown plants, Davallia Moreana being 7 to 8 feet over and very fine. He had also a good Cyathea, Dicksonia, &c. Mr. Sheen, gardener to E. Brooke, Esq, Highgate, and Mr. Child had remarkably good groups, Adiantum farleyense being very fine in these collections. Mr. Carr, gardener to G. P. Hinds, Esq., also staged fresh, healthy, half-grown specimens in good condition. In the nurserymen's class Mr. Williams had large Alsophilas, a Dicksonia, two capital Gleichenias, and a nice Adiantum farleyense. This was a fresh healthy group.

In the classes for fine-foliage plants valuable groups were exhibited. A bright and beautiful collection, but not the largest plants, were staged by Mr. Legge, gardener to S. Ralli, Esq., Clapham Park. His Crotons Weismanni and interruptum were in fine colour, Alocasias were capitally grown, and the whole group in the first order of health. Mr. Donald staged large and really good plants of Cycas circinalis, a Pandanus, Crotons, an Alocasia, and Chamærops humilis. Mr. Strahan, gardener to P. Crowley, Esq, Croydon, had also glossy plants of great excellence. Mr. Carr, Mr. Ritchie, Mr. Child, Mr. Toms, and Mr. Wheeler also exhibited highly creditable collections. In the nurserymen's class Mr. B. S. Williams staged a fine Pandanus Veitchii, two Crotons, two Palms, and a very good Gleichenia.

The Orchid bank was one of finest of recent years. In the amateurs' class for twelve plants Mr. Ward, Mr. Wheeler, and Mr. Heims competed with not large but clean healthy plants of the well-known popular kinds. In the corresponding nurserymen's class Mr. B. S. Williams had a group of great excellence, and Messrs. Jackson & Sons also staged an excellent group. The principal plants have been previously enumerated, and it must suffice to say they were in the first order of health, and in brilliant condition.

In the class for six plants (open), Mr. Denning, Mr. Ward, and Mr. Williams exhibited grand collections in the richest state of bloom. Mr. Morse and Mr. Ritchie also staged capital plants. Mr. Denning also exhibited six plants in the miscellaneous class, the spikes of bloom of Odontoglossum coronarium and Aërides maculatum being the most noticeable.

Roses were not numerous. Messrs. Paul & Son, Cheshunt, exhibited large plants, amongst which Camille Bernardin, Juno, and Céline Forestier were the most effective; also a remarkably well-grown collection in 8-inch pots. This firm also exhibited cut blooms of a new Rose named, in commemoration of His Majesty's visit to the Show, the Sultan of Zanzibar. This is an English seedling, with velvety petals of extraordinary richness; it is not sweetly scented. Messrs. Veitch also sent a handsome group of Roses in pots, small plants, with several boxes of cut blooms. Mr. Turner also exhibited cut blooms of great merit.

Pelargoniums made a grand display. For nine show varieties in 8-inch pots (open), the largest were from Mr. Ward; his plants were 3 to 5 feet across. Smaller plants, but with larger and better blooms, came from Mr. James. Messrs. Dobson and Sons had a nice even lot. In this class Mr. Turner, however, had the finest flowers. Ruth, a charming salmon-pink, should be grown by everyone; Charlemagne, Pompey, Blue Bell, Sultana, and Prince Leopold are also varieties of undeniable merit. In the amateurs' class for six plants Mr. James and Mr. Herrington staged very good plants. In the class for six fancy Pelargoniums in 8-inch pots (amateurs), Mr. James, gardener to G. W. Watson, Esq., Isleworth, staged handsome examples of culture, the plants averaging 4 feet through, and densely bloomed. Mr. King, gardener to R. Fenn, Esq., Esher, having also plants in first-rate order. Mr. Donald also exhibited nice plants. In the corresponding nurserymen's class Messrs. Dobson & Sons had nice little plants, but far behind the amateurs in quality. Mr. Turner staged remarkably well-bloomed small plants, and also exhibited several new varieties. In the class for six Zonal Pelargoniums in 8-inch pots (amateurs), Mr. King, gardener to R. Fenn, Esq., Esher, had beautiful flat plants 4 feet across, Clipper killing the rest by its brilliant colour; the lights, Rose Rendatler, Delightful, and Mrs. W. Paul being good. Mr. Herrington staged larger plants, Clipper being again the brightest. Mr. Catlin also exhibited well. Really fine new Zonal Pelargoniums were exhibited by Mr. Burley, Brentwood, and raised by R. B. Postans, Esq.; Squire of Weal, scarlet; and Leveson Gower, salmon, being the best in their colour which we have ever seen. The same exhibitor also sent a brilliant Coleus Alexander Ogg.

In the class for eighteen hardy herbaceous plants, in three genera, Mr. Parker, Tooting, staged a remarkably well-grown and attractive collection, comprising Liliums, double Pyrethrums, Spiræas, the pretty Erigeron purpureus, Orchis foliosa, &c., also cut blooms of double Pæonies and Pyrethrums. Mr. Wheeler also exhibited hardy plants.

In the miscellaneous class Messrs. Veitch & Sons set up a large, rich, and valuable group, from which it is impossible to select the best by the general high quality of all. The Gloxinias were splendid. Mr. Williams also staged a superior collection. Messrs. E. G. Henderson & Son staged new fine-foliaged plants, richly coloured Tricolor Pelargoniums, and good Calceolarias—a bright and good collection. Mr. Laing and Mr. Lay, Croydon, had good groups; and Messrs. Rollisson & Sons exhibited a fine pan of the charming Bertolonia Van Houtteii, Dionæa muscipula, and Pteris serrulata var. Applebyana. Mr. Bull sent excellent Dracænas and Crotons, also a fine mixed group of plants, including a new climbing plant, Marcgravia paradoxa, with green Begonia-like leaves, clinging as closely to a board as if they were gummed. Mr. Bull also exhibited the decorative Pelargonium Victoria, which is a variety of great usefulness. Nine handsome Caladiums were exhibited by Mr. Clarke, gardener to W. Shuter, Esq., Hampstead; and six beautifully grown Mosses were staged by Mr. Mearing, gardener to W. Whitley, Esq., Guildford.

About twelve o'clock the Sultan of Zanzibar and suite arrived at the Exhibition. The greenhouse plants and Roses appeared to have greater attractions for the distinguished visitors than the Orchids and tropical plants. They appeared much gratified with the display, and well they might be, for it was one of great excellence. We had not time to wait for the awards.

EARLINESS OF THE SEASON IN THE ISLE OF MAN.

As an illustration of how early a season it is here this year, I may state that Potatoes which I planted on the 1st of March were dug on the 27th of April, and then averaged ten full-sized tubers per root, averaging about 3½ inches long. These were grown in the open air without a particle of protection of any kind—not even a little litter.

I have hundreds of Roses in full bloom in the open air, and had abundance of them all through the last week in May. Not only the Hybrid Perpetuals, but such Roses as Homère, Triomphe de Rennes, Céline Forestier, Lamarque, and Climbing Devoniensis are perfect sheets of bloom, and the old Gloire de Dijons are perfect masses of bronzed yellow.—A. D., *Ramsey, Isle of Man.*

Peach.—*The Condor.*—"We received the specimens of this handsome Peach last summer from Messrs. Rivers & Sons of Sawbridgeworth. The sample we obtained was about medium size, of a roundish depressed figure, with a deep suture, terminated by a small nipple-like point. The surface was very finely downy, and the whole fruit tinted as if washed over rather lightly with pale rosy red, the colour not being very dark at any point, while towards the crown it became a little marbly. The flesh was whitish, slightly blotched with red about the stone, and very juicy, rich, and piquant in flavour.

"Our examples were received about the end of July, and had therefore probably been grown under glass. The variety is said to have been raised from Early Silver, and to be a large Peach of a bright crimson colour, ripening early in September. The glands of the leaves are reniform."—(*Flor. and Pom.*, 3 s., viii., 133.)

[The plate of the Condor Peach is a very inadequate representation of that variety both in size and in colour. The Condor is a large fruit, indeed one of the largest Peaches grown, and its skin has a pale flesh colour, over the surface mottled with a deeper shade of the same, and not the brownish orange which is given to it in the plate.—Eds.]

Hereford Rose Show.—An advertisement announces this to take place on the 29th inst., and as we are told that it is the oldest of our Rose Shows, and certainly its prizes are very

liberal—its firsts being £12, £6, £5, and £3, with others in good proportion—we think it is most deserving of encouragement.

FRAGRANT ROSES.

I HAVE waited for some of the known authorities in Rose culture to take up Mr. Camm's subject—fragrant Roses; and as this is not yet forthcoming, and as I have long interested myself by specially noting, year after year, all the best Roses known as to their fragrance, I beg to offer for the benefit of your readers a list of the most fragrant of those Roses otherwise also most desirable and good; and though smell, like colour, is hardly a sense to be dogmatic about, yet I do offer the list as quite trustworthy:—Abel Grand, Bessie Johnson, La France, Comtesse C. de Chabrillant, Edouard Morren, Centifolia Rosea, François Michelon, Jules Margottin, Louisa Wood, Mad. C. Joigneaux, Alfred Colomb, Beauty of Waltham, Dr. Andry, Duc de Rohan, Général Jacqueminot, Mdlle. Marie Rady, Marie Baumann, Senateur Vaisse, Camille Bernardin, Duchesse de Caylus, Charles Lefebvre, Louis Van Houtte, Mad. Victor Verdier, Claude Levet, Fisher Holmes, Duke of Wellington, Duchesse de Medina Cœli, Prince Camille de Rohan, Pierre Notting, Vicomte Vigier, Xavier Olibo, and Mons. Boncenne. All the above are Hybrid Perpetuals, and are, so far as I know, the most delightfully fragrant; at the same time and in all other respects they are the most to be desired of the Roses actually in cultivation.

I would remark there are differences in the character of the scents, though I think, broadly speaking, they may be reduced to a family of two, La France and Abel Grand representing one character or type, and Louis Van Houtte and Vicomte Vigier the other, though I know not which type is the more delicious.

As to Teas, Madame de St. Joseph, Devoniensis, Goubault, Souvenir d'un Ami, Maréchal Niel, and Madame Margottin are the most delicious; but I must add many Teas have little scent, and some few are even offensive at times.—AMATEUR.

DOUBLE PYRETHRUMS.

NOT greater is the difference between the common Daisy and the most perfect German Aster than exists between the common Pyrethrum and the beautiful double flowers which have been exhibited at South Kensington by Messrs. W. Kelway and Sons. The improved varieties of the double Pyrethrums are, when well cultivated, border flowers of great value and usefulness, and will find their way into all gardens where hardy flowers are cherished. The varieties referred to were not flat unsymmetrical blooms of dingy colours, but were handsomely-shaped blooms, perfectly double, and in colour clear and decided.

We have here a class of plants which are deservedly rising in public estimation, for they are free in growth, hardy, effective in the garden, and attractive when used as cut blooms, for which purpose they are particularly adapted, as they last and travel well. These plants are of the most easy culture, and will contribute a valuable feature to mixed beds and borders, where they are certainly worthy to have a place. To grow them to perfection, however, they should be cultivated in beds to themselves, where deep and good soil and a liberal supply of water can be given (liquid manure occasionally), and such blooms will be produced that will grace any exhibition of cut flowers.

When kept in pots they can be planted at any time, but established plants are best increased by division in the spring just when they show the signs of growth after their winter's rest. They will flourish in any ordinary garden soil enriched with manure, and will bloom from May through the early summer months if duly supplied with water. As they grow each stem should have a separate stake, or the heavy heads injure each other by being battered with the wind.

The following varieties are the best down to the present time; they vary in colour from pure white to rich crimson, with shades of yellow and lilac. The blooms are as perfect, large, and full as are those of quilled Asters, and they are made known simply because they are worthy of being grown by all who ornament their gardens with hardy border flowers. Paul Gaurnal, bright pink; Capt. Nares (Kelway), crimson; Duchess de Brabant, rose; Mons. Barrel, purple crimson; Ceres, flesh; Adonis (Kelway), bright rose; Nemesis, rose and bronze; Imbricatum, crimson and white; Mont Blanc, white; Wilhelm Krumper, mauve; Galopin (Kelway), crimson scarlet; Cleopatra (Kelway), white tinged yellow; Eugénie (Kelway), white; and Duchess of Edinburgh (Kelway), rose and white. The above are varieties of undoubted merit, and if justice is done them in cultivation they cannot fail to give satisfaction to those who possess them.—J., *Battersea.*

RAVAGES OF THE GOOSEBERRY BORER.

THE Gooseberry is very extensively grown in the village of Grindleton, four miles from Clitheroe, and the gardens are this year visited by a pest which threatens to annihilate the crop. It is in the shape of a greenish white grub or caterpillar, which perforates the fruit, and this then falls off. So extensive are its ravages, that one man estimates that there are now six hundred quarts of Gooseberries lying under his trees, and my informant says that he has forty dozen quarts (the Gooseberry is here sold by the dozen quarts) under his own trees. As I have not seen the pest I do not know whether it has legs like a caterpillar or is like a maggot, but I fancy it must be a caterpillar, as my informant says that when it has finished one berry it goes to another.

This pest is quite new to me, as, although I have grown this fruit for fifty years, I never saw anything of the sort either in my own garden or in the gardens of any of my friends; but it seems to have been known for some years at Grindleton, though never to the same extent as this year. I am sending a man for some of the berries with the pest in them, and mean to send you some specimens, for I fancy they cannot be generally known, or I should have seen some notice of them in your columns. The only pests to the Gooseberry here are the caterpillar of the sawfly and the green aphis; but this pest at Grindleton is represented to me as far worse than either or both together. I recommended my informant to scrape up all the Gooseberries from the ground, and either burn or scald them immediately.—J. G.

[The Grindleton pest is the caterpillar in its young state of a small pretty moth, called by entomologists Geometra vauaria. The caterpillar is commonly known as "the Gooseberry Borer." The berries with the caterpillars in them should be gathered together and destroyed, for they will speedily give birth to moths. The moths will appear at the end of this and in the next month, and children and others should be employed to catch them. The moth is thus described by Professor Westwood, with a coloured portrait, in his "British Moths and their Transformations:"—"This common insect measures about 1¼ inch in expanse. The wings are ashy white or pale ashy brown, with four generally equidistant chocolate-coloured patches on the costa (front edge), the third of which patches is slender and oblique, and the fourth larger and rather square. Adjoining the second is a dark mark like the letter < thus placed; beyond this is a row of minute dark dots placed on the veins; the hind wings are nearly immaculate, but with a small dusky spot in the middle. The caterpillar is brownish or greenish (those sent to us were green) spotted with black and slightly hairy, with a pale dorsal line and yellowish lateral lines."]

OUR BORDER FLOWERS—UVULARIAS.

A SMALL group of spring and early summer-flowering hardy herbaceous plants, chiefly from North America, introduced more than a hundred years ago, but are very rarely met with. They are well adapted for either rockwork or border culture, where they have an elegant appearance when they have attained their growth. Under favourable circumstances the taller kinds will grow nearly 2 feet in height. They require liberal treatment and thorough drainage. The ground should be broken up to the depth of 2 feet at least for their reception, and should have some good sandy loam, a little peat, with a portion of well-decomposed manure worked in for them to grow in; when well established they last many years. The plants are liable to be attacked by slugs, and should be carefully watched while the shoots are in a young state.

Increase is effected by root-division, which is best done when the plants have matured their growth. They enjoy the full sunshine, and should not be crowded or shaded by other plants, otherwise they will not be seen to the greatest advantage. The dwarfer kinds are fine objects on the rockery, and in the border Uvularia perfoliata when well established has a very elegant appearance; the same may be said of U. amplexicaulis. I look on this as the best of the group, and not despisable for exhibition purposes. U. flava is of very

dwarf habit, suitable for the rockery. U. lanceolata is a charming plant for the border, and one of the tallest of the family. There are several other kinds of this interesting family of border flowers that will well repay any little labour bestowed upon them.—Veritas.

CUCUMBER, TENDER AND TRUE.

In the garden at Farning Woods, the seat of Lord Lyveden, we recently saw that excellent Cucumber Tender and True growing for the first time. It is now some time since it was certificated by the Royal Horticultural Society, but the difficulty of procuring seed from it has hitherto prevented it being grown to any extent. At Farning Woods Mr. Freeman, the skilful gardener at that place, succeeds with it to perfection. In a low span-roofed Cucumber house it is producing fruit of the handsomest kind in great abundance, and Mr. Freeman considers it the finest Cucumber he has ever cultivated. Our own observations confirm all Mr. Freeman has said in its favour, for nothing could be more handsome; and its great merit is the rapidity with which it comes to maturity. In fifteen days from the time of setting, the fruit is as many inches long, and the fine prolific plant in the house had been produced in ten weeks from the sowing of the seed.

INTERNATIONAL HORTICULTURAL EXHIBITION AT COLOGNE.

We have received from Mr. Robert Warner the following extract from a communication he has received from the President of the Exhibition:—"The Minister of Agriculture has put at our disposal six large medals of state, which the Jury will have to award for the best horticultural, &c., contribution to the Exhibition. Moreover, Her Majesty the Empress-Queen has graciously promised a special prize of honour, and undoubtedly His Highness the Crown Prince will do the same."

The Carter Cup value fifty guineas, of which the accompanying is an engraving, and other valuable money prizes for vegetables offered by James Carter & Co., are to be awarded at the Royal Horticultural Society, South Kensington, July 7th, 1875. For the best collection of vegetables, twenty-four dishes: First prize the "Carter Cup," value fifty guineas, to become the absolute property of the employer to whom the prize may be awarded, also 10 guineas for the gardener; second prize, 7 guineas; third prize, 5 guineas; fourth prize, 3 guineas. All vegetables to be grown by *bona fide* gentlemen's gardeners or gentlemen amateurs, and, excepting Cucumbers and Melons, in the open ground.

Fig. 109.

Largest Peach Orchard in the World.—Mr. Shellcross, who resides near Middletown, Delaware, owns the largest Peach orchard in the world. Last year he shipped to New York 125,000 baskets of fruit, and it is estimated that he lost, by being unable to procure labour to pick, about 25,000 baskets more. On several days he loaded from his orchard ten carloads. Mr. Shellcross's orchard reaches along the public road for more than eight miles—generally on either side—and covers an extent of upwards of a thousand acres, on which is growing more than a hundred thousand trees. The land on which Mr. Shellcross's trees are planted is worth 150,000 dollars.

THE GOOSEBERRY CATERPILLAR.

The green caterpillars, larvæ of the Saw-fly (Tenthredo grossularia), are earlier and more numerous this season than I ever remember. I can vouch with some of your correspondents that the cuckoo is a great enemy to them, and so are sparrows and chaffinches. The easiest way which I know of eradicating them is to keep a sharp look-out as soon as the insect comes into real life, and look over the bushes three times a-week and pick off the leaves that the insects have been hatched on. There will be twenty-five to forty on a leaf. A small boy will look over two or three hundred in a day, and if this is continued for two weeks or so there will be no danger from these pests. I have about six hundred bushes, and this is the way I almost defy the caterpillar.—J. Addison, *Ormiston*.

CUT-BACK ROSES.

In answer to "E. A. W.," I have to say that I am writing principally in the interest of Rose exhibitors, but my remarks apply with far greater force to those who merely want garden Roses, as there can be no question that the blooms on cut-back Roses are much more profuse than on maidens. By the term "cut-back Roses," I mean Roses other than maiden plants; Roses which come from nurseries, or old plants in the garden which have been pruned. I did not think at the time I used the term that anyone would not know its meaning, or I would have written more at length. A desire to save your space, as well as a wish to make my articles lively and pleasant to your readers, makes me use terms which are well known to all large growers, but may prove enigmas to the uninitiated. Concerning pruning, I will write to you at length before next season.—J. B. M. Camm.

LOXFORD HALL.

Not a place of imposing appearance is Loxford Hall. It is no castellated structure with terrace and moat surrounding it, or the ancestral home of a long line of landed magnates, but it exemplifies the position of those of whom a nation may be proud to boast. Loxford Hall is a plain brick building, cosy and comfortable; but it is noted mainly for its gardens, its worthy occupier having invested freely and liberally in erecting structures on a large scale, and in a substantial manner, for the culture of flowers and fruit, of which the metropolitan and provincial exhibitions have seen such superior examples. In the management of these gardens it is pleasing to record the confidence which exists between master and servant; hence it is that Mr. Whitbourn and his able gardener Mr. Douglas have done and will do so much for high-class and useful horticulture.

To the readers of our Journal a sketch of this garden cannot fail to be interesting, seeing that in our columns the "Doings" of its manager are literally household words—teachings given by actual example, profitable and valuable because thoroughly practical, and a faithful reflex of current work. A celebrated man when asked as to the character of a contemporary celebrity replied, "I do not know, as I have not lived with him"—a cautious and a pregnant answer. Ours, too, is a practical age, and while we are pleased to hear what a man has to say, we are only quite satisfied when we see what he does. We see Mr. Douglas's doings in the Journal, let us now glance at them at Loxford. Does some one inquire if he really does all that he says? the reply is, Yes, and more, for like most able men Mr. Douglas possesses a modesty which forbids any parade of his own works. He does not hesitate to tell us if mealy bug finds its way on a Stephanotis, or red spider on a Vine, or if an Orchid is injured by fumigation. Many would hesitate to acknowledge such incidents as being evidence of unskilfulness, but a cultivator conscious in his own strength and desirous to be the instructor of others, can afford the risk, and does not hesitate to tell of a mistake or an untoward occurrence when with it goes a proved remedy or timely precaution. Mr. Douglas will tell us all that, but he will not pourtray his noble Grapes, splendid Pines, excellent Strawberries, and fine stove plants, Orchids, and Aurieulas.

It may be seasonable to adopt his familiar headings, and look first into the

STOVE AND ORCHID HOUSE.

This is a span-roofed structure of moderate size, having a

central stage and marginal trellis with a pathway round and between the plants. The first plant which arrests attention is the Clerodendron Thomsoniæ. It has long been a dense wreath of white and crimson bloom, and indeed a splendid object, affording cut flowers in great abundance and of long duration. Mr. Douglas has good reason to recommend this as a roof plant, as enjoying a singular immunity from insects, is a free grower, at once ornamental, useful, and long-lasting. It is planted-out behind the pipes in a narrow border along the base of the wall. This is clearly the way to grow this valuable decorative stove climber. It has as a companion the well-known Stephanotis, the glossy leaves of which denote that soapy water has been used, or they would not be so clean and handsome as they are, or its waxy flowers be of such great size and substance. It is also planted out, and is evidently enjoying the treatment. Another useful roof plant, as yet young but flowering freely, is the Bougainvillea spectabilis.

The general collection comprises Ferns, Palms, and fine-foliaged plants in the very first order of health. It is not necessary for a plant to be new to have a home at Loxford, but only requires to possess merit, when justice will be done it; hence we find the Alocasia metallica still cared for and splendidly grown; Eucharis amazonica in exuberant health, and affording three crops of flowers each season. The reason why some fail with this plant is, Mr. Douglas believes, that they have the "shy-flowering variety." It is well to mention this as explanatory of the productiveness of the plant in one place and its barrenness in another. Anthurium Scherzerianum is in fine form as to size of plant and number of flowers, a duplicate plant being remarkable for the great size of its spathe. Dracænas are well grown, D. Cooperi being especially brilliant in colour. This and D. terminalis are still as useful as ever, notwithstanding the claims of the newer introductions. D. reginæ is also in robust health. Caladiums are well grown and in the full sun; C. Belleymei and C. argyrites alone requiring shade. When grown in the sun the leaves are better in colour and texture than are those in the shade, which are flimsy in comparison, and flag on being moved from place to place.

The best of the Palms are Cocos Weddelliana, an elegant pair of the most elegant Palm in cultivation; the Cocoa-nut Palm, Cocos nucifera, raised from the nut, the shell of which still envelopes the stem; and the fine bold Palm Phœnicophorium Seychellarum. Areca "aurea" is also grown as green as a Portugal Laurel, the yellow hue disappearing under good cultivation, which is the best cure for "aurea" in other plants besides this misnamed species.

Ferns are admirably cultivated. It is not necessary to enumerate, but we noticed two which should be in more general cultivation—Adiantum colpodes, the young fronds deeply tinted with pink, and Davallia polyantha, a species with fine spreading fronds, both fertile and barren, each being very distinct. There are also fine examples of D. Mooreana, Pteris scaberula, and Stag's-horn Fern, Platycerium alcicorne.

Turn we now to the Orchids. The collection is not extensive but choice, and the plants are in undeniable health. In bloom were Dendrobium Macarthiæ, beautiful, and remarkable for its long-lasting property; D. Devonianum, D. Bensoniæ, of faultless beauty; D. Farmeri, and D. thrysiflorum carrying a raceme which for size, symmetry, and colour has probably never been surpassed. Oncidium phymatochilum had a grand spike laden with quaint flowers; O. papilio and others were also in bloom. Lælia purpurata was exceedingly fine both in size, and richness of colour, and Cattleya gigas showing. This beautiful species can only be grown on a block, where it is now doing well. Masdevallia Harryana is remarkably fine; but even more brilliant in colour is a distinct species in this collection, and worthily named M. Whitbourniana. It is of the most fiery magenta colour imaginable, and very free. Calanthe veratrifolia is also striking, and Mr. Douglas will oblige by informing us how he grows this useful plant so well. Also in bloom is Strelitzia regina, a remarkable plant, the flower stem being 4 feet high, surmounted by brilliant orange and purple flowers of singular form and very striking.

GREENHOUSE AND CONSERVATORY.

Here is a splendid plant of Lapageria rosea in the rudest health; it is planted out and covers a large space on the lofty back wall. Azaleas, of which there are good specimens of Criterion, Iveryana, Magnificent, very pure, Duc de Nassau, Duchesse Adelaide de Nassau, &c., were in fine bloom at the time of our visit.

Seedling Azaleas, of which Mr. Douglas has a fine batch, are also opening, some of the flowers being of immense size and semi-double, a most promising lot of plants to be watched with interest. Mr. Douglas grows the Oleander (Nerium splendens), which is one of the best of conservatory plants. Tree Carnations, of which we have a hint now and then, have immense blooms, and are found invaluable. Roses were heavily laden, a small houseful of them, but we can only name one as a button-hole Rose—Madame Jules Margottin—which is truly lovely for that purpose.

Aquilegias were in beautiful bloom. Why are not these more grown? A. pyrenaica is very rich and effective, so also is A. cærulea, to say nothing of the fine and stately yellow A. chrysantha leptocera aurea which has deservedly won a first-class certificate for its excellence. A long narrow house is devoted to Liliums, of which a large number of choice sorts are grown. L. Humboldti is throwing three spikes, one of them containing thirty buds. L. puberulum, L. Washingtonianum, L. californicum, &c., are also very vigorous. Most useful during the summer will be this valuable collection.

FRUIT HOUSES.

Fruit from these houses has frequently proved the best of the best, having secured first honours in Grapes, Pines, Melons, and Cucumbers at the principal exhibitions. It has been hinted that there are employers who calculate prize-money as a part of their gardeners' wages. It is not so here, and we record it in honour of Mr. Whitbourn that the more his gardener has won the more has he increased his remuneration. That is a just encouragement of merit, a recognition of energy, labour, and skill, and the greatest incentive to sustained effort and devoted service. But to the fruit, commencing with the

Vineries.—We will neither count the houses nor the Vines; suffice it to say the early house is not large, but the Grapes in it are. The Black Hamburghs are ripe—several bunches cut, and for those who may think that prize bunches are chance bunches, one big to ten small, we may fearlessly say that almost every bunch in the house might fitly grace an exhibition table. We have seen larger bunches, but crops of such level excellence as is this are certainly few and far between. The berries are black, large, and "hammered," and their finish is almost perfect. The crop is regular, the bunches being as large at the bottom as at the top of the house, and the yield is a full one. The Vines are planted inside, but the roots have access to outer borders. The inside borders are mulched, and the Vines well supported.

The pruning is what may be termed the long-short-spur system, and we note Mr. Douglas is not above laying-in a young shoot where he wishes to have a good bunch. The young wood is thinly disposed, not the slightest crowding, but still a leaf wherever the sun can shine on it. The shoots are stopped two or three leaves beyond the bunch, as there is space for them to occupy, the object being to lose neither leaves nor light—that is evidently the principle of the summer routine of dressing. There are no rambling laterals, and no red spider, dust, or dirt. That is how are produced these beautiful Black Hamburghs and clear and bright Buckland Sweetwaters which have made Loxford famous.

We step into a later house. Thinning is going on. But what is that Grape, the bunches touching each other, each 18 inches long and heavily shouldered? That is Waltham Cross. Soberly speaking it is a splendid sight. If Mr. Paul has done honour to pomology in raising that Grape, Mr. Douglas is doing honour to Mr. Paul by growing it in this manner. By its side is Royal Ascot, a splendid crop of great promise, growth vigorous and bunches fine. Snow's Muscat is carrying a great crop of very even bunches. Douglas's Seedling, a pretty Grape, is also swelling-off freely a nice crop.

We pass outside, and between one house and the next is covered-in—a glassed space 5 feet by 3 feet. In this is planted a Muscat of Alexandria; the cane is taken in the end of the house, and trained horizontally along the base of the rafters. From this horizontal main are three canes trained up the roof at wide intervals. The space in which the Vine is growing is 5 by 3, and 3 feet deep. From this root-encased Vine is a crop of Muscats, which for full setting and regularity of bunches and berries is a sight worth a long journey to see. The bunches are models of perfect setting and swelling. In Grape-growing we have seen nothing more interesting than this industrious Vine. Bones fresh from the butchers were broken and mixed in the soil, which is the only difference in its treatment from the rest. If that is the secret of its remarkable health, we can

only conclude that there is much virtue in raw bones. Mrs. Pince's Muscat is also bearing heavily. But we must leave these well-managed Grapes to glance at the

Pineries.—Pines are not largely grown, but are as good as the Grapes. The plants are dwarf, dark green, and vigorous, and throwing-up fine fruits. That Mr. Douglas can take great prizes from such a few plants is the more to his credit. In most cases Vines are grown overhead but do not overshadow the Pines, but in every house every plant is healthy.

Melons and Cucumbers.—These are grown in houses on trellises. The Melons are in cleanliness and health all that can be wished for—the fruits even in size on each plant, and swelling regularly. Victory of Bath and Scarlet Gem are esteemed the best in their sections, but Mr. Douglas mainly grows his own hybrids, and with these satisfies at home and wins prizes abroad. Of Cucumbers a word must suffice. If Mr. Douglas had done nothing but raise Tender and True he would, as Mr. Camm says, "deserve well of his country," for it is the best Cucumber that has ever been given to the public.

Tomatoes are grown in pots at the back of the house. The crop is very large and the fruit ripe, affording gatherings of great value and usefulness.

Strawberries.—The fruit then staked-up above the plants, large, and colouring well, is now gathered. The plants are grown in 48-sized pots, perfectly healthy, and free from red spider. Dr. Nicaise is bearing a heavy crop of fine fruit, but large numbers of plants are Mr. Douglas's own seedlings, which require more time to prove their worth; we can only say they look well.

ORCHARD HOUSE.

This is a good-sized structure, filled with large trees in disproportionally small pots. Pears, Cherries, Plums, Peaches,

Fig. 110.—Loxford Hall—the pleasure grounds.

and Nectarines are thoroughly clean and bearing heavily. It is only by skilful culture that such crops can be perfected. We have no more to say about the fruits, but in this house is a novelty worthy of mention. Phormium tenax variegatum is throwing-up a spike of bloom. The spike is fully 11 feet high, and producing numerous branchlets. The plant is healthy, with fine striped foliage 5 to 6 feet in length, and is a specimen of great value and interest. Mr. Douglas must describe it when in bloom, for such a circumstance is rare if not unprecedented.

FLOWER GARDEN.

Of bedding-out there is little to mention. Mr. Douglas is too much of a florist to indulge in massing and grouping. What beds there are, are filled with fine plants which have not much growing to do to meet. The lawn is planted with a few good Conifers, but the grass is burnt up by drought, the soil, about 3 inches, resting on gravel. It is beds of Pinks, Carnations, Phloxes, Gladiolus, Hollyhocks, &c., grown thoroughly which constitute the flower garden here, with a few herbaceous plants, the brightest and best at the present time being Lithospermum prostratum, recently noticed in these pages. Remarkably effective is also a bed of the old Giant Brompton Stock with blooms as large as Roses, a valuable and nearly lost strain of this fine old garden flower. Mr. Douglas prizes it, and well he may. There is also a bed of Scilla peruviana blooming, the plants raised from seed sown six years ago.

KITCHEN GARDEN.

This is two acres in extent and well cropped. It is only by thoroughly working that such a soil can sustain the fruit trees and vegetables in good health. Strawberries are very promising, so also are the large fruits. The trees are duly pinched and pruned; they are not toy trees, but such as bear great quantities of fruit. The walls are covered with trees, fan-shaped, vertical and oblique cordons—indeed something in every style of gardening is carried out here, and carried out well. Peas are looking well, the earliest now gathered. All the new sorts are grown, William the First is the first and best, and Alpha second. Premier Gem is very fine in growth and habit, and regarded as a valuable acquisition. G. F. Wilson and the best mid-season sorts are in the full vigour of active growth.

Our parting word must be with the

Auriculas.—These are Mr. Douglas's favourite plants, and right well he grows them. His collection is extensive and choice. They are repotted and growing vigorously in frames at the north side of a wall. Something has been said on cutting down the plants; Mr. Douglas cuts them over with as little compunction as he does a Geranium. We take as an example Colonel Taylor. The label denotes that it was cut down on April the 30th. The top is already struck, and is a stocky sturdy plant, and the plant has pushed five shoots now an inch long to form five plants by the same course of beheading. It is the only way of increase, and is certain when

carefully done. The wounds are dressed with lime. If any fanciers have scarce sorts which they wish to become more plentiful they had better send them to Loxford, for these plants are very tractable in Mr. Douglas's hands. Our notes are concluded by thanking Mr. Douglas for his courtesy and attention.

DRACÆNAS.

Very unlike the usual ornamental-foliaged plants we find in our stoves is the example now figured. The engraving represents a matured specimen—a tree, while those usually grown as decorative plants are more or less succulent, like other young trees, and are furnished with beautiful arched foliage to the surface of the pot. As the plants attain age the lower leaves mature and drop off, and the stem assumes its ligneous character. Yet by high culture and skilful treatment the foliage is retained until the plants attain a height of several feet, increasing in size with the plant, and also improving in colour. The system adopted is to preserve the plant in a succulent state as long as possible, by preventing woody layers being formed, or, at any rate, consolidated. Such plants are very beautiful, as the examples which have this year been exhibited by Mr. Bull and Mr. Wills sufficiently testify.

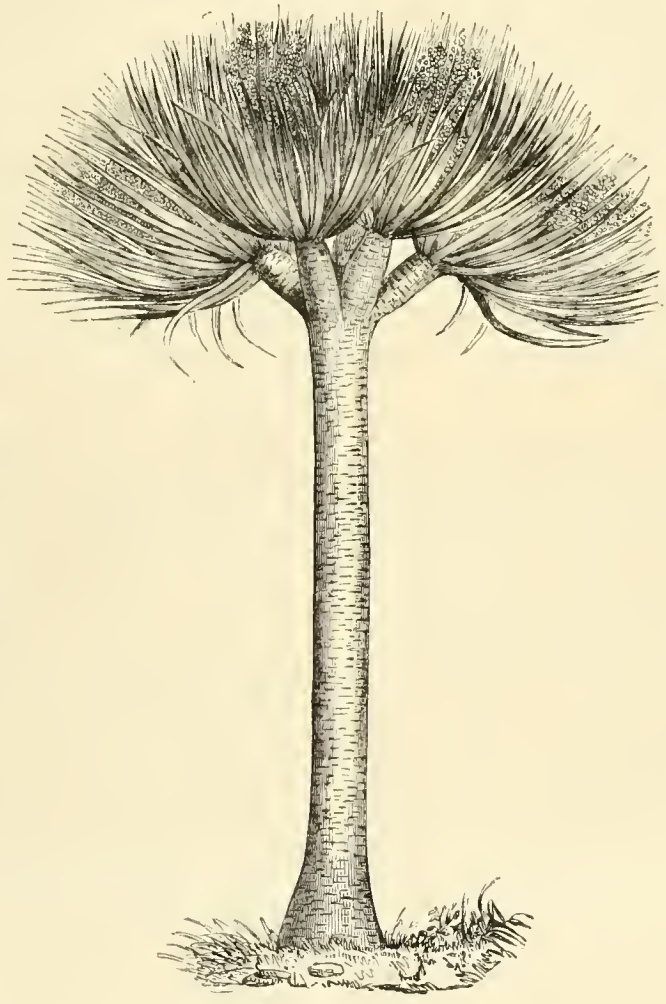

Fig. 111.—Dragon tree (Dracæna draco).

The fresh and bright plants we usually see do not at all suggest the size and aspect they attain in their native habitats. Dracæna draco, for instance, of which we grow attractive plants varying from 1 to 6 feet in height, is frequently found growing 30 to 40 feet in height; and it is on record that a specimen in the Canaries is 75 feet high, and 45 feet in circumference at the base. Although for general purposes young highly-coloured plants are the most serviceable for indoor decoration, older specimens which have approached the tree state have a distinct and imposing effect when agreeably disposed in suitable structures. Most of them require heat, especially those having variegated foliage, yet even these when approaching a state of—shall we say treedom?—are highly ornamental both in a glass structure and for occasional effect on the staircase or corridor.

But there are the hardier green-foliaged kinds which are valuable for conservatory effect, and for associating with flowering plants to form attractive groups for any decorative purpose. Some of these add a diversified feature to the sub-tropical garden in summer, and all are worthy of cultivation wherever convenience is afforded for this class of plants. Some which are adapted for cool treatment are D. (Cordyline) indivisa, D. lineata, D. australis, D. cannæfolia, &c. The beauty of these increases with age, and they afford an agreeable relief to collections of flowering plants, toning-down their colours and breaking-up their smoothness of surface.

Of the tropical and richly-coloured Dracænas we have a list which for intrinsic beauty with variety are unsurpassed by any other genus of stove plants. They are not frequently grown to a flowering state, the practice being to cut-down old and propagate young plants, as better fulfilling the purpose for which they are required; yet we have repeatedly seen the old species, as D. draco, D. terminalis, &c., in a flowering state, but they are more interesting than ornamental. D. Smithii, figured in the "Botanical Magazine" as having flowered at Kew and Sion House, has, however, double yellow flowers of undoubted beauty.

It is a little surprising, considering the time many of the species have been introduced, that more English hybrids have not been raised. The Messrs. Veitch have, however, led the way with a variety of great merit, a cross between D. magnifica and D. albicans. D. hybrida is a beautiful decorative plant, its deep rose and creamy white variegation being very telling. Hybrids are also raised by other firms, and there is no fear of experiencing a lack of novelties in this family of plants.

It is extremely difficult to make a choice of a few from the long list of beautiful Dracænas now offered. But notwithstanding the richness of the recent introductions, the old D. terminalis and D. Cooperi are still useful as ever. They are, however, less imposing than such kinds as Shepherdi, Youngii, Fraseri, regina, triumphans, splendens, imperialis, Hendersonii, Baptistii, and others equally fine, especially some of the latest introductions, which show their markings when in quite a small state. One of the most distinct of all, however, is D. Goldieana. It is quite unlike any other either in shape of leaf or colouring. In the generality of Dracænas the leaves are ensiform or lanceolate, and the variegation is longitudinal; in D. Goldieana the foliage is cordate, has a dark green ground, with regular diagonal bars of silver-grey. This should be grown in all collections.

The Dracænas are not only handsome plants, but they are of easy culture, high stove heat, copious supplies of water, and rich but open soil being the essential requirements. They are propagated by cuttings of the stems inserted in brisk heat, or by knobs which form on the roots around the sides of the pots. The last mode is certain in its results, and a stock is gradually increased without mutilating a specimen. If the work is carefully done these root-knobs may be severed from the plant without doing it any harm.

D. draco—Dragon's Tree, is so called from yielding a gum resembling the substance known as dragon's blood, which is extracted from the fruit of Calamus draco. D. terminalis is to the Polynesians a plant of great importance. The root is cooked and eaten by the natives, and also manufactured into beer and spirit. The leaves supply fodder for cattle, and afford coverings for roofs, and are also woven into cloaks by the natives. Hedges are formed by sticking its truncheons in the ground, where they readily take root and grow. In former times its leaves were the native emblem for peace, and, with

those of the Plantain, were a substitute for a flag of truce. It is, then, no small compliment to this plant that it combines with its beauty uses so important and beneficent.—W.

PLANTS FOR A GRAVE.

Equally with "F. B., *Blackheath*," do I detest seeing graves planted with gaudy flowers. There is something repugnant to the appropriate feelings of our nature to see the resting places of the dead attired in the colours of a clown's dress in a circus. Yet do I like to see the graves becomingly tended, and to this purpose I will thank you to allow me to lay before your readers a simple style of grave decoration now much practised in the North of England. It is much admired by strangers, and is becoming every day more general here.

Where the space allows the grave is made of the ordinary size inside the railings of the tomb, and is covered with soda from the seashore, the grass of which is very fine and of a beautiful green throughout the year. Around the outside are planted Snowdrops for winter, these are followed sometimes by Hyacinths, and for the summer a few Ferns are used. Thus, in the summer months, flowers are altogether discarded, and nothing but the Ferns are seen, and the effect is at once quiet and graceful. For an ordinary grave the sexton is requested to leave the mound a little less than the usual size, and the remainder of the space is occupied by Snowdrops and Ferns. In addition to the appropriateness and good taste of this style of grave decoration, it possesses the advantage of requiring the very least of attendance. Both the Snowdrops and the Ferns will last for many years, and all that is required is an occasional cutting of the grass on the mound, and the keeping the other parts free from weeds.—Beta.

SAVE THE SLOPS.

Let everyone who owns a garden, whether in town or country, bear in mind that the waste water, highly impregnated with ammonia and other valuable fertilisers, that annually goes to the gutter, would make many a man rich. Now that every well-arranged kitchen has a sink with a waste-water pipe attached, the latter should in every instance have its outlet in some portion of the vegetable garden. A tank, not necessarily large, should be the reservoir for receiving all the contents, and if no higher than the surface of the surrounding ground, and covered with a neat board floor, it will not prove unsightly. The centre of the garden is the proper place for its location, and a small force-pump will at all times enable us to use the liquid portion of the contents. The sediment, which will mostly settle to the bottom, should be taken out as often as it interferes with the working of the pump, and immediately composted as an incomparable manure for Vines. After a reasonable length of time it becomes as mellow and rich as anyone could desire, and causes the richest tint of green to spread over the Melon and Cucumber leaves. Indeed, for Lima Beans there is no fertiliser so well adapted as this. The liquid portion of the contents of the tank may be pumped up, and by the aid of inexpensive wooden troughs can be conveyed to any portion of the garden where it is needed. The Celery, treated to an occasional dressing of this, will outgrow any plants ever seen in the garden.

In early spring, however, is the season when its virtues are most needed. A sprinkling over the seed beds of Cabbage, Celery, &c., will prove equal to the best "home-made" liquid manure. The overflow pipe (for there must be such an arrangement) should lead into a neatly-kept gutter, and on either side of this, if one or two rows of Strawberry plants should be set, there will be an astonishing growth of foliage followed by a surprising crop of fruit.

The best arrangement of this kind is where there are two tanks, connected near the top by a short pipe. The waste water, sediment and all, runs into the first of these, when the solid portion sinks to the bottom, while the liquid fills the tank, and, passing through the communicating pipe, is held by the second tank. Over the latter should be fastened the pump for the convenience of using the stimulating fluid; but in the first tank will accumulate all the solid matter, which may remain therein for some time, or until it should fill the vessel and retard the passage of the water in the communicating pipe. As this contrivance has been successfully tested by some of the most practical gardeners of my acquaintance, it should come into more general use, as the idea of a person purchasing several dollars' worth of manure for his garden when he has an almost inexhaustible supply without cost at his very door, is simply ridiculous.—(*American Tribune*)

NOTES AND GLEANINGS.

On the site of the ancient castle of Benefield in Northamptonshire there is a handsome old Ash tree, the branches of which droop in the same manner as those of the Babylonian Weeping Willow and of the Scampston Elm. It is a very graceful and ornamental tree.

—— In the garden of Mr. J. Smith, the Rectory at Oundle, is a polygamous Mulberry bearing an abundance of male and female catkins. This is an unusual occurrence, as the Mulberry generally met with in gardens produces female flowers only.

—— In the conservatory of Mrs. Webb, West Side, Clapham Common, is a fine specimen of the Eugenia Ugni. The plant forms a close green column about 4 feet in diameter and nearly 30 feet high. The stem is fully 30 inches in circumference at the base. This fine plant is very ornamental, its glossy foliage being enlivened by white flowers and fruit in different stages of ripeness. The fruit, of which Mr. Pithers the gardener has picked considerable quantities, is about the size of an oblong Gooseberry. It possesses a peculiar piquant flavour agreeable to some palates.

Smith's Improved Metallic Garden Labels.—These are painted a light ground colour, and the names in raised metallic letters are black. They are very superior labels, but care must be taken to have the names correct. One sent to us is "Cupressus Lawsoni" instead of Lawsoniana.

NOTES on VILLA and SUBURBAN GARDENING.

KITCHEN GARDEN.

In this locality dry weather has prevailed for so long that many crops, where water could not be applied, have shown signs of languishing. Within the last week, however, plentiful showers have fallen, and greatly improved the aspect of plants in general. The rain has been especially welcome in those little spots occupied by amateurs' gardens, where little or no shade is produced by surrounding vegetation. It is in such places where crops have suffered most, and where work has been delayed either in sowing or planting on account of the dry state of the soil. In any neighbourhood where such a state of things has existed, and rain has fallen, there must be no delay in putting out all kinds of plants, such as the main crop of Brussels Sprouts, for if these are not planted-out early enough to make a vigorous growth before autumn the produce is likely to be short and the sprouts very small. This vegetable is a profitable one for an amateur, and worth growing well. The plants should be planted 2½ feet each way, and in rich soil they will grow to a large size.

All sorts of Broccoli too, where the plants are of a proper size, should be planted-out during showery weather, and they are assisted to make a natural start, such as they cannot have in very hot dry weather. Spring-sown Cabbages also must not be neglected. Some people depend upon the spring bed for a supply, but my experience is that towards autumn they are tough and not of such a nice flavour as those which are grown quick and cut in a young state. Plant-out a full crop of the Drumhead and Dwarf Green Savoys; these may be planted 2 feet each way. While on these I may say that a sowing ought to be made of Wheeler's Cocoa Nut or Little Pixie Cabbage, and the Rosette Colewort for early autumn Cabbages; they are quick-hearting kinds, and may be planted closely together. Plant many of the winter and spring greens, I mean Tall and Dwarf Curled Kale, Scotch Cabbaging and Cottagers' Kale, and Dalmahoy Sprouts, leaving the coarser sorts to follow later on as ground falls vacant. Plant-out a full crop of Cauliflowers now. There is none better or more select than Veitch's Autumn Giant, and those from seed sown the latter end of last month may be put out as soon as ready.

Make a good sowing of Peas, such as British Queen or Ne Plus Ultra. I usually make another sowing of some one or other of the early sorts in the first week in July; these have at times cropped fairly, and have been exceedingly useful. Sow also dwarf green Gem Beans for autumn use where they are in request, and another crop of Dwarf Kidney Beans, as well as the last crop of Scarlet Runners. These later sowings are sometimes the best in this vegetable, as they do not grow so high, and are in full bearing till frost destroys them, while the early crops are exhausted.

Plant Celery in the trenches as soon as possible. I generally plant two rows in a trench 18 inches wide, putting the plants 1 foot apart in the row. I believe for Celery to keep during

winter it must not be grown too large, but a medium-sized plant is the best for all purposes. When once planted-out the plants must never suffer from the want of water, and they will be crisp and of good flavour. Some advocate shading the plants, but I do not do that if I can manage to take up my plants with plenty of soil to the roots, and plant them before they are become overgrown for the purpose. There is a proper time for this work, and an effort should be made to have it done at the time.

In a showery time like the present the opportunity should not be lost to sow a good breadth of Orange Jelly Turnip, or any other favourite sort. The plants come up quickly, and grow away from the reach of the flea, which in dry weather will eat the little plants up. With me early Turnips have done well. I am pulling the Early Stone and White Dutch, both of which I consider have escaped the flea by the free use of wood ashes and soot, and they have been excited in growth in consequence. They have also been supplied with an abundance of water.

Plant Leeks at once, either in trenches or on a border of rich soil; the former plan is the way for them to grow firm and quick. Thin-out the crops of Beetroot if it has not been done, and fill up vacancies by pricking-out some of the plants not wanted otherwise. Those who grow Endive may now make a small sowing of Digswell Prize or Green Curled, and later on, in addition, the Broad-leaved Batavian and Moss Curled; the latter sort is very tender and useful, and so compact as to almost blanch of itself, but it is not so hardy as the other sorts, and will not stand the winter well.

Sow also two or three different sorts of Lettuces, to be planted-out thickly for use in July, August, and September, and another sowing in the first week in July; the sorts may be All the Year Round, White Cos, and Lawe's Black-seeded Bath Cos; the latter sort is a thorough good autumn Lettuce—hearting like a Cabbage.

Among the general work to be done is to keep the hoe plying between all growing crops, and stake early all those plants that stand in need of support. Leave off cutting Asparagus, and keep the beds clean during the summer. Attend to the training of Tomatoes on walls, and water them well. Give a mulching or top-dressing to them and all other plants situated in hot places, and water very plentifully everything that stands in need of it. Vegetable Marrows and outdoor Cucumbers keep pegged-down and trained; stop some of the principal shoots to incline them to throw out bearing shoots. Radishes must now be sown in moist shady places, or they will be hard and stringy.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

As soon as possible we shall attend to the bush and pyramid trees. The shoots must now be stopped, and when necessary thinned out. No fruit trees will give satisfaction if they are not attended to in summer. Bush, pyramid, and cordon-trained trees are not out of place in any garden, but they are specially adapted for amateurs who are the owners of small gardens, and who like to do much of the light work themselves. In rich light soils the trees have a tendency to produce much unfruitful wood, and the frequent stoppings sometimes instead of causing fruitful growths, merely produce a thicket of young wood; of course this is when the trees are young. The certain remedy is root-pruning in autumn, but even in summer much may be done by a judicious thinning-out of the growth. No good fruit will be produced if the trees are a thicket of wood, for sun and a free circulation of air is essential to produce both quality and flavour. A few words of explanation is perhaps necessary for those who are as yet but beginners in the art of summer pinching.

The largest proportion of young wood is produced at the ends of the branches. A shoot of last year's growth which has been cut back will start one strong growth from the end, and also a number of side growths. These last must be pinched or cut back to a leaf or two, and the leading growth to six or seven leaves. If it is desirable to increase the size of the tree the young growths must be allowed to develope themselves more; even side growths are necessary, and must not only be allowed to remain where they are required, but also be stopped at the right bud. If the growth is required outside the tree, stop at an outside bud, and *vice versâ* if the tree is not sufficiently furnished internally.

Cordons are very easily trained: the leading shoot must be trained along the wire without stopping it, and all side growths cut back to a leaf or two. A few varieties of fruit trees produce long straggling growths partially bare of buds. Where this is the case the leading growths may be stopped once or twice during the growing season, each time when the young shoot has made six or seven leaves. It will be a good opportunity when summer-pinching the trees to remove all fruit attacked by the Apple borer. A small hole may be observed in the side of the fruit, or after careful inspection concealed in the covering of the eye. The best way is to burn the fruit at once.

Peaches and Nectarines on walls ought now to receive a final thinning. There is abundance of fruit this year, and it is a great mistake to overcrop. The shoots must also be trained into the positions they are to occupy, and a sufficient number be retained to fill up all vacant spaces. We do not usually stop the young growths on wall trees, but if a strong shoot could be trained where there is room for two or three, stopping this would cause the requisite number to start, but very weak growths might not start at all. If any branches have died off it is highly necessary to fill up the vacant space by undoing the adjoining branches from the wall and training them in its place.

It is absolutely necessary to protect Cherries and Strawberries from the attacks of birds; indeed, it is scarcely possible to secure any Cherries for the owners' use without nets. The best plan which, though attended with considerable expense at first, is to form an enclosure round the trees; they require to be planted together when this is done, the sides of the enclosure as high as the trees may be of wire netting quarter-inch mesh, and over the top ordinary netting may be used. Small fruitful trees may be protected with netting thrown over them. Wall trees are easily protected. The netting is nailed along the top and bottom of the wall, and kept from the trees by sticks a foot long with forks at the end; these stand out from the wall, and the forked end holds back the netting.

ORCHARD HOUSE.

The fruit has now been thinned out, and all the trees are carrying good crops of fruit. We were very much annoyed with aphis, and the trees just at the time the fruit was setting suffered from it, but fumigation has been resorted to, and the trees are now clean. They have also been surface-dressed. When commencing the culture of fruit trees in pots we were very careful to use the mixture recommended by Mr. Rivers—viz., malt or kiln dust, road scrapings and manure, but the kiln refuse has not been readily obtained, and a mixture of stable manure and loam has taken its place; the manure and loam in equal proportions are thrown together in a heap, which soon heats violently, and after being turned over daily for ten days or more until the heat declines it is ready for use. This mixture is spread thinly over the surface of the pots, a fresh dressing being applied every ten days until the fruit shows signs of having finished stoning. The copious supplies of water wash the rich dressing down to the roots, and a mass of young rootlets work up into the dressing. We syringe twice a-day—early in the morning, and when the house is shut up in the afternoon.

VINERIES.

The early houses are being rapidly cleared of the fruit, and this makes an opportunity to syringe the leaves to free them from red spider. In previous seasons sulphur was applied to the pipes, and this insidious pest at least kept in check. In two early houses the sulphur was not used, but in the third, which was attacked almost as soon as the fruit was set, the spider increased so rapidly that it was feared the crop would not ripen before the leaves were destroyed. The enemy had first taken up a strong position in a Royal Ascot Vine, always the first to be attacked, and from this vantage ground it had spread from end to end of the house; now here was an excellent opportunity to show whether the sulphur would destroy the pest or not.

The pipes were heated as hot as was thought to be consistent with safety, and all of them were coated with the flowers of sulphur dissolved in soapy water to the thickness of thin paint. Next morning the leaves were examined, and the spider to all appearance had not suffered. At night another coating was applied, and the pipes made still hotter; on the following morning some of the spider had suffered, but many were alive. Again the dose was repeated, and the pipes heated until a thin haze could be discerned in the atmosphere; this was the signal to damp down the fires, as just a trifle more might be too much for the Vines. We examined the leaves next morning very confident as to the result, not with the naked eye but through a magnifier, and there they were hanging to the under sides of the leaves in hundreds, not one alive! and at the same time not a leaf nor berry injured (the berries had finished stoning). What say Mr. Pearson and other good Grape-growers, who say that sulphur will not kill red spider, to this experiment? It is only right to say that this is a very hazardous practice, and that sulphur often causes rust on the fruit.

If there are any shanked berries they ought to be carefully cut out with the scissors, as they are an eyesore. Try to keep dust from the berries, even if it is necessary to frequently water the ground outside the house. If any sweeping is required inside the house a little water should be sprinkled about to prevent the dust. If all the fruit has been cut—(and this is where the market gardener has an advantage over the private grower, as the one cuts all his fruit as soon as it is ripe, and the other must allow it to hang for two months or more)—the leaves should be well washed with the garden engine and the border watered.

Late houses require considerable attention as to airing, watering, and keeping up the required amount of moisture in the

atmosphere. Stopping the growths must also be done in time, for it is positively injurious to the Vines to allow the laterals to extend themselves, and then to cut them out in armfuls or even barrowloads. The balance between the roots and branches must be evenly maintained.

GREENHOUSE AND CONSERVATORY.

The stage Pelargoniums will soon be over, and their places will be well supplied with Fuchsias that have been grown-on out of doors for some time and kept from flowering by being stopped. The Fuchsia may be brought into flower at any time, and is a highly decorative plant. Greenhouse plants are now being placed in positions out of doors, those exposed to the sun have a tile laid against the pot, as the heat is thus prevented from injuring the roots. Many plants require repotting, and will be attended to as soon as possible. Placing Chrysanthemums in their flowering pots. Those intended for specimen plants have been repotted three or four weeks ago. The plants for cut blooms are potted two and three plants in a pot; the largest pots used are 13 inches, and the smallest 8½ inches in diameter, inside measure.

FLOWER GARDEN.

The bedding plants had shown signs of distress from the continued drought, and we had to water them; fortunately rain came, yet the watering was of much benefit. Pinks are just coming into flower, and are very fine; the lacing has come out well. The difference between autumn and spring plants can be seen in the imperfect lacing of the latter. Phloxes have been frequently watered; they suffer sooner than any other plants. Carnations and Picotees are doing well, though they were not improved by exposure to the recent drying winds. During hot dry weather syringing twice every day is beneficial to them.—J. Douglas.

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

York.—June 16th, 17th, and 18th. Mr. Jno. Wilson, 13, New Street, York, Sec.

Exeter (Rose Show).—June 18th. Mr. T. W. Gray, Queen Street Chambers, Hon.-Sec.

Fareham.—June 23rd. Mr. H. Smith, Sec.

Stowmarket.—June 24th and 25th. Mr. S. Prentice, Hon.-Sec.

Crystal Palace Company.—Rose Show, June 26th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.

Reigate (Rose).—June 26th. Bushby Brittee, Esq., Hon.-Sec.

Wisbeach.—June 30th. Mr. C. Parker, Hon.-Sec.

Maidstone.—(Roses), June 30th, at Vinters Park. H. Benstead, Esq., Hon. Sec., Rose Club, Mill Street, Maidstone.

Norfolk and Norwich Horticultural Society.—Rose Show, June 30th. E. A. Field, Hon.-Sec.

Birmingham.—July 1st, 2nd, 3rd, and 5th. Mr. Quilter, Aston Park Sec.

Spalding.—July 1st and 2nd. Mr. G. F. Barrell, Hon.-Sec.

Baockham Rose Show.—July 3rd. Rev. Alan Cheales and Charles Mortimer, Esq., Hon.-Secs.

Southgate.—July 3rd. John Miles, Esq., Hon.-Sec., Southgate, N.

Grantham.—July 6th and 7th. Schedules, &c., from Mr. Lyne, Bookseller.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Books (*H. E. M.*).—The new edition of "The Greenhouse, its Plants and their Management," free by post for ten postage stamps.

Select Strawberries (*J. C. P.*).—*Early*—Vicomtesse Héricart de Thury and Keen's Seedling. *Main Crop*—President, Sir Joseph Paxton, British Queen, and Elton.

Picea pinsapo's Leader (*Kittie*).—The leader of a Conifer may be restored by grafting on the stump remaining the leader of a side branch; or one of the uppermost side branches may be turned by degrees to a perpendicular position by training it to a rod fastened firmly to the main stem.

Royal Horticultural Society's Show.—Mr. Dixon, Norwood Nursery, Beverley, was second prizetaker for one of Mr. Bull's cups.

Disease of Peach Leaves (*Mrs. Carlisle*).—It is a well-known disease called "Peach blister." In this instance it is accompanied by a fungus named Ascomyces deformans, but the fungus is said by some observers to be not always present. We are of opinion that the blistering is caused by spring frosts rupturing the sap vessels, and that the fungus lives on the extravasated sap.

Gold Fish in Greenhouse Tank.—Gold fish will live in the tank, but you must have some aquatic plants growing in it, and the bottom covered with sand and fine gravel mixed.

Lily (*C. A B.*).—It is only a variety of the Martagon Lily, but the Editors do not remember seeing before one of the same colour.

Dahlia Shows Suspended.—"In what year was it that there was no Dahlia show held? and was it in consequence of the Dahlias in that year being so fearfully infested with thrips?—A., *Coventry*." We shall be obliged by any of our readers sending us a reply.

Window Boxes (*W. W.*).—The best plants are such as are usually employed for bedding-out, having a few of each of the following Zonal Pelargoniums—Iantha, crimson; Master Christine, pink; Vesuvius, scarlet; The Bride, white. Golden Tricolor—Lady Cullum. Bronze—Black Prince and Prince Arthur. Silver-leaved—Bright Star and Prince Silverwings. Double-flowered—Aurora. Centaurea candidissima, silvery foliage. Fuchsias—Sunray and Delight. Calceolarias—Aurea floribunda and Sparkler. Verbenas—Eclipse, crimson scarlet; Clarinda, purple, white eye; La Grande Boule de Neige, white; Melindres splendens, scarlet. Lobelia speciosa and Blue King. Ivy-leaved Pelargonium—Silver Gem and Dolly Varden. Sweet-scented-leaved Pelargoniums—Pheasant's-foot and Lady Plymouth. The Verbenas, Lobelia, and Ivy-leaved Pelargoniums should occupy the margin, and the middle be filled with the others. The variegated Thyme is also good for the margin, especially the variety Thymus citriodorus aurea, also Gazania splendens fol. var., and Alyssum variegatum. We have, no doubt, named too many for your purpose, but you may select from them to meet your requirements. A Clematis would not flower to meet your wishes this year, but if you want something to run up the sides of windows, Lophospermum Hendersonii and Maurandya Barclayana, and its white variety alba, are neat and would answer; so also would the Canary plant, Tropæolum canariense.

Roses for an East Aspect (*Flora*).—Hybrid Perpetuals will be the most likely to succeed, selecting those which are of vigorous growth, a few of which are—Abbé Bramerel, Alfred Colomb, Annie Laxton, Auguste Neumann, Auguste Rigotard, Baroune de Rothschild, Baroone Louise Urkull, Capitaine Lamure, Charles Turner, Comte Raimbaud, Comtesse d'Oxford, Duke of Edinburgh, Edward Morren, General Miloradovitsch, Jean Cherpin, John Hopper, Jules Margottin, Leopold II, Louisa Wood, Louis Van Houtte, Madame Canrobert, Madame Hippolyte Jamain, Madame Laurent, Madame Victor Verdier, Mdlle. Eugénie Verdier, Paul Neron, Perle des Blanches, President Willermoz, Princess Beatrice, Reine des Blanches, Senateur Vaisse, Souvenir de Julie Gonod, Susanna Wood, Thomas Methveo, Victor Verdier, and Xavier Olibo. They require very liberal treatment, and should be watered abundantly overhead in dry weather.

Irises and Liliums for Wet Ground (*Idem*).—Irises that would probably succeed are I. De Berghi, I. germanica many varieties, I. Kæmpferi, and vars. Alexander Von Humboldt, Duchesse de Belcourt, Humboldti, and Le Souvenir, Kæmpferi and its varieties doing best in sandy peat soil, I. fœtidissima variegata having fine white-striped foliage. Of Liliums we can only advise one—viz., L. superbum.

Melon Stems Cankering (*W. B.*).—The canker at the stem and roots immediately near the stem is caused by a superabundant supply of moisture after the stem has been for a time dry, and not unfrequently is caused by the stem being covered with leaves; or drip from the lights falling on the stem will cause it. The only remedy we know is to remove the leaves which cover the stem, and not water over the stem, but keep a clear space of about 6 inches from the stem all around, and if any canker appear upon the stem rub it dry with quicklime, and dust it over with it after the operation. Examine the plants frequently, say two or three times a-week, and if any canker continue rub it dry with fresh lime, dusting again as before, and by continuing it the best results may follow; it may be overcome, or at least the plants continued until the fruit is ripe. See that there is no drip upon the stems from the lights; we do not see the necessity for Melons in your case being sprinkled overhead daily. The atmosphere is too moist for plants in the state yours are, and we should either discontinue it, watering two or three times a-week, as the state of the weather shall determine, and a little air at night will do much to keep down the canker by allowing any excess of moisture to escape. The Lycopodium we presume you wish to have named is Selaginella cæsia.

Fernery Watered with Corrosive Sublimate (*E. B., Halifax*).—It is very likely the roots as well as the fronds will be destroyed, but we should give the plants or rather the soil a thorough watering with rain water, and await the result. If they do not shortly recommence growth, your only remedy will be to remove the plants and soil, and replant.

Peas and Cucumbers for Mid-September (*W. Dumbell*).—Your Peas should be sown at once, and unless of an early kind they will not be in at the time you require, as the early kinds require about thirteen, and the late kinds fourteen to sixteen weeks from sowing to having pods fit to gather. The Cucumbers should be sown about the middle of July, and planted-out the second week in August.

Peach Trees not Fruiting (*W. M. Grote*).—The soil in which your trees have been planted is too rich; it has caused them to make vigorous growth, which is never fruitful. If you partially lift the trees in the autumn and place some fresh loam round the roots it may check the growth for next season and cause the trees to make weaker, and consequently productive wood. The trees planted against the back walls of vineries will be shaded too much.

American Aloe Flowering (*James Haney*).—The spike will grow 12 or 15 feet high, and may be protected from sun and wind in some way. If the plant can be removed to a cool greenhouse, and be shaded from the sun, that would be the best way to preserve it in good condition.

Vine Roots (*James Bell*).—They are quite healthy. The white portion is merely the woody fibre exposed by the bark splitting, owing to its growth not keeping pace with that of the wood.

Fuchsias (*F. O. M.*).—For a pillar in the conservatory, Lustre. For planting-out Riccartoni is one of the best hardy Fuchsias. Sunray and Pillar of Gold are attractive by their foliage. The following varieties flower freely in the open air:—*Lights*: Rose of Castille, Wiltshire Lass, Conspicua, Alba Coccinea, Marginata, and Evening Star. *Darks*: Try Me O, Constellation, Lizzie Hexham, Norfolk Giant, Rifleman, and King of the Doubles.

Black Hamburgh Vine (*Fidget*).—At Winchester a Black Hamburgh Vine bears well in a garden on a wall facing the south and sheltered from cold winds.

Azaleas (*Clifton*).—Keep your plants in the vinery to make their growth, and until the flowers are formed in the tips of the shoots. This is easily determined by the fingers. At any rate do not turn out the plants until the Grapes are approaching ripeness, and not necessarily then providing the fruit colours and finishes well. If thrips are on the Vines and plants fumigate on two or three successive nights. Syringe the plants heavily twice a-day, and once a-week with warm soft-soap water of a strength of 2 ozs. to each gallon of water. This will keep your plants clean, and the moist atmosphere will be precisely suitable for the Vines until the fruit begins to colour; water must then be discontinued, and the Grapes and wood of the Azaleas will ripen at the same time. The plants may then be placed in the open air.

Vine Leaves (*G. A. B., Louth*).—There is nothing objectionable in the

state of the Vine leaves. The Vines are very vigorous, and the roots supply sap to the leaves faster than they can elaborate it, so the vessels are unnaturally expanded.

INSECTS (*A Subscriber*).—The insect you have sent, supposing it to be a drone (male) wasp, caught flying about with queen wasps, is a solitary insect belonging to a different sub-family. It is named Bynerus parietinus, and builds its nest in old walls and sand banks.—I. O. W.

NAMES OF PLANTS (*Madeira*).—We cannot name from flowerless specimens, or mere scraps of Conifers. (*F. B.*).—We cannot name from leaves only, nor florists' varieties even from flowers. Your Begonia leaves are from such varieties. (*J. Lansdell*).—We believe it to be Clitorea ternatea, Wing-leaved Clitoria. A portrait of this plant is in the "Botanical Mazagine," *t.* 1542.

POULTRY, BEE, AND PIGEON CHRONICLE.

GRIEVANCES AND CORRESPONDENCE.

AMONG all the different hobbies taken up in the present day, we doubt if there is ever as much dissatisfaction in any of them as there exists at times in the poultry fancy. So many are dissatisfied, and grumble because they think their own burden is the heaviest, or that their troubles are the most intolerable. Perhaps this may not only be the case in our department. Anyhow we know among many poultry-loving individuals dissatisfaction frequently reigns supreme. Let us take a monthly or a quarterly number of our Journal, or that of any other poultry contemporary, and we are able to pick out grievances on every conceivable subject—eggs, prizes, birds sold and birds bought, shows, *et id genus omne*.

We fear individuals who delight so in grievances gain but sorry comfort and poor consolation from their friends, and still less from the fancy. The former call them idiots for embarking on the road at all, and the latter think them equally foolish for either not taking greater care of number one, or else treat their pitiable effusions as rubbish. We are not hard-hearted, and we have had as much to put up with, we believe, as anyone, but we do wonder why people do complain so much. Is it that they wish to be pitied for the troubles and calamities they undergo? Do they love to parade their misfortunes before this unsympathising world to show how nobly they bear them? Do they think they will be the means, by circulating their troubles, of bringing about better times? Or do they complain for the very love of grumbling? We sometimes are almost obliged to believe the latter is the real state of the case.

We must not be misunderstood when we speak of grievances, for we do not mean that fanciers should not show up and do their utmost to stop wrong practices, for we can thoroughly sympathise with those who have had their birds tampered with or purposely rendered unfit to win, and we hope when a case of any such kind can be clearly proved nothing will prevent the circumstances being fully presented to the public. It is not to that kind of grievance we would refer, but to stupidly concocted woes proceeding from fertile imaginations. These are the grievances we object to, and would beg those who make them to consider first the incalculable trouble they put their correspondents to, and secondly the absurdity of the very grievances themselves, and consequently the ignorance that is exhibited by those who do complain. We were calling the other day on a lady who had just entered the poultry arena, and who, having made her *début* in exhibiting, was not as satisfied with the results as she had fondly hoped to have been. One thought, consequently, a letter on the subject, not for insertion, but a private kind of sermon, might do the editor of a poultry paper some good. Well, a letter was penned, and this was the substance of it.

"Mrs. A regrets very much having to trouble the editor, but she feels sure he cannot know that her beautiful Light Brahma cock did not win the prize at C. Mrs. A was very much disappointed, and does not pretend to hide it, for she had given 30*s.* for the cock without basket or carriage, and understood the bird was to be a winner. Mrs. A herself tied-down the basket, and can vouch for the cock being in perfect health. Certainly the cock's comb was damaged in fighting, and he had rubbed most of his leg feathering off. There were also bare patches on his back, but these were only in consequence of the hens having eaten his feathers; still Mrs. A believed the judge would have given her bird the prize, for he must have been able to see the points of her beautiful bird. Mrs. A leaves the matter happily in the hands of the editor, feeling sure he will find out the true state of the case, and see that her birds have justice done to them in future."

This was the letter we just prevented being dispatched, and we believe it to be a type of many dozens with which editors and managers are weekly assailed. As we told the lady, surely if she only thought the matter over she could see that the editor of a paper could do her no good. How could he see her birds had justice done to them? How could he make the judge perceive the perhaps non-existing points? Private people, however, come in for their share of grumbling letters, and that no small one. Here is a ridiculous case. A friend of ours, a gentleman well known in the fancy as a successful exhibitor, sent a dozen Dorking eggs off to a party who had ordered them. Within three days after they had been sent off (we are not certain it was not within two), back came the basket of eggs, and a letter which said that the eggs arrived and being tested were found to be all clear, and so another sitting at once would oblige. This we call the most original impropriety we ever heard of, for allowing the time to have been three days, one-half of the seventy-two hours to have been consumed in the transit of the eggs, this genius in the remaining thirty-six hours had, we supposed, placed the eggs under the hen, taken them away again, tested them, found them to be clear, and again sent them on their journey.

Many are the letters, too, egg-sellers receive, telling of dire disappointments because only six or seven out of the sitting of eggs have hatched, or because the chickens died in the shells, or were "rotten," not "clear." We must answer the letters, and we must enter into their difficulties to a certain extent, but we do hope we may soon find that people are more reasonable, and cease to entail such immense trouble upon a body of fanciers who in many instances are people that take up poultry as a recreation and as an amusement after business hours, and who, if by selling birds and eggs try to make the two ends in the poultry establishment meet, have no time to reply to needless correspondence.

Secretaries of shows come in for a large share of troublesome letters. We have a pile by us of epistles sent to one of the authorities of a large show held last year. We pick out two of the simplest, for some of them are really difficult to understand, so wonderful are their expectations:—"Sir, I usually am happy to remain at the stake, a martyr to the glorious cause of poultry; but here I must say a word. Such mismanagement should be sent forth to the world, and I give you timely notice, unless I hear by telegram why my birds did not reach home by the mid-day train on Friday instead of the morning of Saturday, I shall write to the Editor of the *Journal of Horticulture* and beg him to publish the case." The telegram was not sent, but the matter ended with the above. This is the second one:—"Sir, where is my catalogue? I sent you a penny for postage! and let me hear by return whether you gave my birds the bread and milk at 6 P.M. as per injunctions; also kindly let me hear if Mr. A's Hamburgh cock was the one with the long tail, or the one with the malformed comb. I should like to hear the weight of the prize Rouen Ducks, not both of them, only the drakes; and do you know if the pen was claimed in the sale class? If not, please forward on the enclosed to the owner to save a post; if, however, it was, I should be glad to have my enclosure back, and a card stating name of purchaser and his address. Do not forget the catalogue and weight of the drakes. P.S.—Do not forget the catalogue, mind, and to see about pen ——, it must be that pen."

This is the correspondence secretaries have to endure. Do let us all try not to trouble secretaries and members of committees more than we can help, for they are generally men who do their work for the love of the fancy, and who have to put up in most cases with loss of money as well as loss of time. Above all, let us hope for a cessation in the style of correspondence of which we have been speaking.—W.

SCHEDULES OF SHOWS.

PETERBOROUGH holds its poultry show on June 29th and 30th. Entries close on Saturday next, June 19th. Lady Huntly, and her daughter Lady Grace Gordon, are great patronesses of this Exhibition, and supply more than a quarter of the prize money. The prizes are small and classes few. There are two classes for 1875 chickens and two for table poultry, and an extra prize of £1 for the best pen in the Show. The entry fees are low: for non-members only 2*s.*, for others 1*s.* each pen, and the modest charge of 6*d.* for Pigeons. Surely here is a chance for the cottagers.

BUCKINGHAM holds its second Show on July 27th. Entries close on July 13th. It is a very fair schedule, with three prizes in each class. The breeds are fairly well classified, and there are several classes for single cocks, which we should think would fill well, for many have them in good feather, and no hens fit to go with them at this season. The peculiarities of the schedule are a class for spring chickens and two classes for Geese. There are also especial classes for cottagers, of which we are very glad, and we also rejoice to see "several pens of poultry may be sent in one package." The Judge's name, whose decision is to be final, is not declared. Why not? Let it be advertised; it will increase the entries if a good man has been chosen.

CIRENCESTER holds its third Exhibition on July 28th, 29th, and 30th, under a new secretary. Three days for such a show is a most objectionable long time. Entries close on July 14th, and the fees are 4*s.* and 3*s.* for poultry, and 2*s.* for Pigeons. There are two cups for the two best pens of poultry, and a gold medal for the best pen of Ducks. The classes are fairly well

distributed, Hamburghs coming off the best. Pigeons have a point cup, but as there are only nine classes, and the prizes but 10s. and 5s., we do not anticipate much rivalry between the "dealers." So here is a chance really for the badly-treated amateur. We are glad to see more than one pen may come in a basket. The Judge is not announced; we conclude he will be one of "acknowledged ability," and earnestly hope exhibitors will not be disappointed.

Shrewsbury will hold its Show on July 29th and 30th. The names of the Committee and that of the Hon. Secretary are well known, and consequently we shall expect a superior exhibition. The prizes are good, and extra cups numerous; £2, £1, 10s. in each class. Dorkings and Cochins are well divided, and so are the Game. Brahmas, Dark and Light, each have a class, and an extra. Hamburghs have three classes, and Mr. Darby gives them an extra cup. Crêves, Houdans, and Malays each have classes. Mr. Brooke and Mr. Tudman evidently have come to a mutual understanding, the one giving his cup for the other's specialities. We regret very much to see no Poland class in this capital schedule. It is a mistake. Game Bantams all compete together, but there is an extra between them and the Variety Bantam class. No class for Black East Indians. Pigeons have ten classes, but it is not a schedule which will draw; hardly inviting enough to get the Doo Lodge birds down. The Judges are announced—viz., Messrs. Hewitt and Esquilant. We sincerely hope the former will be able to attend. Entries close on the 6th. The entrance fees are most moderate—only 4s. and 2s. This Show deserves patronage. The birds must come in separate packages. We are sorry for this; but still it is at shows where there are single-bird classes that we do so earnestly beg for permission to use double baskets.—W.

THE PRESENT YEAR'S HATCHING SEASON.

Having seen much correspondence and many complaints of the hatching season this spring, especially during the east winds in March and April, I venture, though only an amateur with no extraordinary appliances, to send a record of my experiences. December 8th, 1874, till February 15th, 1875, set 76, hatched 32; March 4th till April 30th, set 161, hatched 123. The pure Dorkings and pure Houdans hatched equally as well as the cross-bred chickens.

The birds for breeding live in slight moveable wooden houses, and have free range; but I am anxious to record my experience of the effect of frost on eggs rather than east wind. I set thirty-six eggs before January 15th, and only hatched out seven, and this I attribute entirely to the eggs having been chilled before they were collected. I shall be glad of the opinions of the poultry connoisseurs as to the necessary minimum temperature in which eggs for hatching should be kept. My experience teaches me they should be collected while warm during severe frosts, and kept in air-proof boxes on the Norwegian stove principle.—A Berkshire Amateur.

[We think our correspondent's suggestion well worthy of attention, and invite our readers to send us their observations.—Eds.]

SELECTION.—No. 1.

I would have entered upon this subject long ere now had not circumstances combined to prevent me. However, on reading Dr. Morgan's paper reprinted in our Journal from the "Pet-Stock Bulletin" I felt it touched a point upon which I am very susceptible. It is neither my desire nor intention to open up an argument, but I shall be glad to see expressed opinions from those who have studied this subject. Dr. Morgan is no doubt a fancier of the first rank, and I wish we had one or two more of his calibre on this side the Atlantic, but I fear his enthusiasm has carried him into those scientific mists through which we can see neither head nor tail. He has launched upon a sea of which he skims the surface only—a sea of depth so infinite that I believe man will never be able to fathom it.

Dr. Morgan starts with the conviction that all our beautiful varieties of Pigeons have sprung from the common Pigeon. I presume he means the dovecote Pigeon. Scientific writers name the small Blue Rock Pigeon as the parent of all: this latter point I shall take up by-and-by. The most unsatisfactory part of the doctor's paper I think is, that all the varieties bred "from the common Pigeon is a simple fact in nature, depending upon selection extended over a period of time." Upon this so called fact the doctor has, he says, satisfied himself, but he has neither satisfied me, nor, if I mistake not, any of our readers. This is just the old, old story, "Once upon a time long, long ago," &c., which does satisfy the child but will not satisfy the man.

The doctor says, "Pouters become smaller and smaller when allowed to intermingle, Carriers lose their wattles and size, Fantails drop their tails, and Tumblers become coarse." By the word "intermingle" am I to understand to cross with each other in those or other varieties? If so, then of course cross-bred birds will be produced, some of them showing more of the characteristics of the father, and others more of those of the mother. This would not be the natural selection of Mr. Darwin nor the artificial selection of the fancier, but compulsory selection. Should the word "intermingle" mean matching as they choose in their own variety, the tendency would be to make the Pouter coarser; but if "smaller and smaller," they would still be Pouters. Carriers may lose the wattle so far and deteriorate in size, still they would be Carriers. Fantails would lose in size of tail, but they would still bear upon their shape and style their original name, the Broad-tailed Shaker. Tumblers may become coarse, still they would be Tumblers; and the rule is, the coarser they become the better they tumble.

Now by reducing some of our fancy Pigeons to common birds through their produce, as Dr. Morgan tells us he has done, he thinks he has proved his so-called "fact in nature," and tells us that "at school we used to do our sums backwards to prove them." True, we used to do so, but this was after we had done our sums forwards. I submit the sum has never been done forwards; it is not on record, not in history. A child has put into his hands a beautiful toy, and often with one ruthless blow utterly destroys it. He knew not who made it nor how it was made, and he cannot make another like it. He, like Dr. Morgan and Mr. Darwin, has done his sum backwards, and has only proved that he has destroyed the gem which was so well worth preserving.

Unfortunately there have been very few real ornithologists, however many copyists, the latter having only promulgated the opinions of the former, and this, I am sorry to think, is still going on. I have read most of the old ornithological works, and at one time held the same opinion as Dr. Morgan, and fancied that I could by "selection" produce a new variety, but after years of care found my efforts unrewarded in the slightest degree. From childhood I have kept common Pigeons, and have them still. How is it, then, that over a period of nearly half a century I have never been able to detect the slightest variation in the young birds except in colour?

Being but a Scotchman I cannot steam ahead in the American style. I like to be sure, however slow. But as Dr. Morgan has thrown down the gauntlet I take it up and challenge him to do his sum forwards. But I go a little further: I offer Dr. Morgan, Mr. Darwin, or any other (ladies included), a silver salver value £50, with suitable inscription, if they produce one new variety, or even any one of the old varieties, from the common Pigeon direct, or from the Blue Rock Pigeon of scientific writers. I go further still: On the same terms produce a new variety with distinctive characteristics by using any or all of the varieties known.

Dr. Morgan tells us he tried to produce white Fantails with black tails, and he used the Nun (a black-tailed bird) as a cross, but that he failed in his attempt; this there can be no doubt of. Then he found "a sport in a friend's loft"—in fact, a Fantail nearly black, and by crossing it with a pure white Fantail he obtained what he wanted. Of course, the whole affair was a mere matter of colour; but what does this teach us? Stick to the variety, or you lose in crossing! But, as Dr. Morgan seems certain that the Jacobin is "not many removes from the common," the experiment will be a short one and the prize easily won.—James Huie.

GREEN CARDS AT THE HULL RABBIT SHOW.

When I saw the "green" prize cards at the Hull Show, and before the poisoning of Mr. Firth's grand buck, and for which four days before the Hull Show I offered £10, I feared that fatal results would arise. I think committees of shows should provide white cards which can be manufactured without mineral poison, and consequently without fatal poisoning results should they be eaten by the Rabbits.

The experience of Messrs. Hudson should have taught them not to have had "green" prize cards, because they could not be ignorant of their poisonous character, and whoever put the "green" prize card in the hamper with Mr. Firth's buck did that which was very likely to end as it did.—G. R. Savage.

[Green cards are objectionable if put into the basket containing a Rabbit. The colour is usually from one of the arsenical salts. Was such a card put into the basket with Mr. Firth's buck?—Eds.]

The Swans on the Thames.—The Dyers' and Vintners' Companies have for several hundred years enjoyed the privilege of preserving Swans on the Thames from London to some miles above Windsor, and they still continue the old custom of going with their friends and guests with the Royal swanherdsman, and their own swanherds and assistants, on the first Monday in August in every year, from Lambeth, on their swan voyage, for the purpose of catching and "upping" (or marking) all the cygnets of the year. The junior warden of the Vintners' Company is called the swan warden; the appointment to the office of Royal swanherd being vested in the Lord Chamberlain for the time being. Eton College has also the privilege of keep-

ing these birds. At one period the Vintners' Company possessed over five hundred Swans, but the number is now much less, as, since they have ceased to be served up at great banquets and entertainments, the value of them has greatly declined.—(*Cassell's Old and New London for June.*)

BELGIAN CANARIES.—No. 1.

Belgian Canaries are not every fancier's fancy, and they are not the fancy either of most individuals who patronise bird exhibitions. Lady visitors in particular have a strong dislike to the Belgian breed of Canary, preferring a cosey-looking high-coloured bird—for instance, a Norwich bird—to the "ugly, consumptive-looking creatures," as they are so often pronounced to be, more particularly those birds of true Belgian form. But it may be asked, When and where are birds of "true Belgian form" to be seen? It is true that at some of the best shows last season a few good birds were exhibited, but it is invariably the case that many ill-formed, sparse-feathered, or part-feathered objects, almost approaching cripples, are sent for competition, which neither gain a mark of distinction for themselves or their owners.

I may mention in particular the last Darlington and Crystal Palace Shows where most of the finest specimens were exhibited, several of which possessed the essential points of high-class-bred birds. This is not of common occurrence, for it is only occasionally that really exceptional birds grace the stages, notwithstanding the frequent "much ado about nothing" made by some self-opinionated fanciers, who persist in "holding-up" their birds as eclipsing all others, despite the opinions of numerous other fanciers and judges included. The best of fanciers are those exhibitors who can bear defeat philosophically, or, as I once heard it remarked, "take their gruel" without becoming ill-tempered. But some fanciers will not be convinced, for

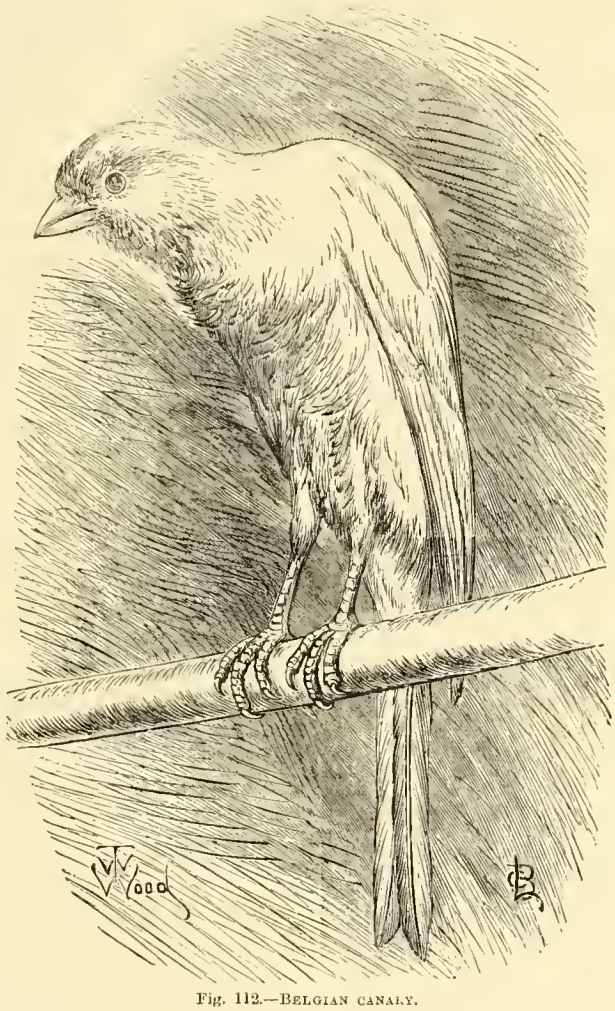

Fig. 112.—Belgian canary.

"He that complies against his will
Is of his own opinion still."

There is some just reason why a mother naturally entertains the notion that her own babe is the best, but with bird fanciers and their birds the matter is very different; therefore, when a fancier enters the birds of his choice for exhibition against others he knows nought of, and the owners of which birds have the equal right to pin their faith upon their particular feathered pets, each and all should make-up their minds to abide by the opinions and decisions of those engaged to decide upon the respective merits of the birds.

I well remember an ardent fancier who disregarded most other points in a Belgian bird except "stand," or as he used to say, a "leggy bird," contending that the bird which could show the longest legs and stand most erect upon them was, in his opinion, the best. But I believe it was looked upon as sarcasm on my part when I told him to establish for such birds the name of "Malay Belgians." Other would-be Belgian fanciers will almost entirely ignore all other points except "shouldera." Good stand and high heavy shoulders are each important points in a Belgian bird, and it is anything but agreeable to the eye to witness a heavy-shouldered bird balancing itself upon its legs with its tail projecting straight out. A bird to rank first at an exhibition should be well up in all or most points to qualify it for so distinguished a position.

I believe it was at an exhibition in the great cotton city, where I had been judging, that a person (who I afterwards found out to be a bit of a fancier), introduced himself to me in a somewhat abrupt manner by asking if my name was So-and-so. I replied in the affirmative. He said, "You've been judging Dutch birds here." I said, "Indeed, I do not recollect such a class in the schedule." He said, "I will show you the birds in the room." Curiosity induced me to follow the man to the Belgian classes, where he made a sudden pause opposite a cage containing a bird which he loudly said, "You ought to have given first prize to." I remarked that I had been judging Belgian birds not "Dutch." The man, who was the owner of the bird in question, appeared somewhat puzzled, and drew down the laughter of the several fanciers who had been listening to his remarks to me. This was merely another instance of the ignorance existing in some minds as to what really constitutes a thorough Belgian bird—understood amongst the *elite* of the fancy to be a bird of position. A Dutch bird is another bird entirely, not possessing the high shoulders of a Belgian bird.

The illustration in our present issue represents a Buff Belgian bird exhibited in Class 15 (No. 479), by Mr. James Doel, of the Prince George Hotel, Stonehouse, Devon. In the same class Mr. Doel exhibited three fine buff birds, the one from which the sketch was taken having been awarded a first prize. In Classes 14 and 15 Mr. Doel sent six specimens for competition, with which he won five prizes.

The engraving represents a three-quarter front view, not the most favourable position to show-off the bird to the best advantage, but still representing the easy style the bird possesses, and which commanded so much the attention of many enthusiastic admirers of Belgian birds at the late Crystal Palace Exhibition. The bird was sketched as it stood at ease upon the stage without either flattery or the fiddling movements being gone through.

The bird is tolerably well-up in most of the characteristic points of a Buff Belgian.—Geo. J. Barnesby.

HASLINGDEN SHOW OF POULTRY, &c.

This was held on the 10th inst., and, like all its predecessors, the day was very wet; in fact no Committee that we know is so unfortunate in the selection of a day, for though changed almost every year, this has been their unfortunate lot. As regards entries this was decidedly the show of the season in this county (Lancashire), and as to quality it is not likely to be surpassed, most of the best exhibitors contributing. The pens were of wood, mostly with wire netting in front, on account of which the birds were rather difficult to handle.

Ducks were the first section, the entries not being large, but the quality of the winners was good, although the Rouens were not in good feather; the cup going to an exquisite pair of Chilian Teal; the second in which class were Mandarins. *Cochins*, Buff, cocks, were very good, the first, not the largest, was most perfect in colour; the second large, but losing in that respect. In hens Mr. Taylor's grand old bird left little chance for others,

standing on in such a manner as to secure the cup offered for these and Brahmas; the second, also a Buff, was very good, while several others were noticed. In Partridge or White cocks the winners were of the first-named colour, both very good in all respects; many others being very good, but with the feet-feathering worn off. In hens a White was first and Partridge second, both very good hens. In Black or Cuckoo the first was Mr. Walker's Cuckoo-coloured cock; the second was a Black, but the first stood clear of all others. In hens both were Black, the first reminding us of hens of this colour which were common but unappreciated twenty years ago. Of *Brahma* cocks there were nineteen entries, and most of these were noticed, the competition being very keen. The first and second were perfect in colour and marking; the third by far the best in shape, but with a bad habit of twisting his tail on one side, showing want of condition; the fourth going to a nice light-coloured bird, which is well known. Hens were very good, but not so regular in condition, some being a little broody; the first was very large, but not as good in shape as the other winners, but in prime order. *Dorking* cocks were a good lot, but the pens a little too small for them, several of the combs being pressed on one side with the tops. Dorking hens were a very regular lot, and every pen was noticed, but the otherwise best bird had very bad feet; first was a Dark, and second a Silver-Grey. *Spanish* came next, and for intensity of interest and earnestness of exhibitors, commend us to the Spanish classes. In this case the birds were well brought out for the time of year, Mr. Beldon winning both prizes with two grand birds; Mr. Boulton's bird coming in for a very highly commended, this being of the same smooth-faced style as the winners; Mrs. Allsopp's bird was nice, but not enough of it; Mr. Newbitt's having a little too much about the eyes. Hens were very good, but Mr. Newbitt an easy winner with a grand smooth-faced hen; Mr. Powell following with the same style of a pullet. *Polands* were very good, but not numerous. In cocks first was a Silver and second Gold, the cup for the section going here; and in hens the same colours won respectively, the second a grand hen, not looking quite as we have seen her. There were four classes for *Game*, with forty-two entries, the cup going to the best Black Red hen we have seen out for some time; the second in that class being a Brown Red, the whole class being good. In Red cocks were also some grand birds, and the win here no mean attainment, the contest being so keen, first a Brown Red of last year; and second a Black Red; next to which was a well-known Black Red, a previous winner, looking awfully shaggy. In the next class a Pile was first and Duckwing second, these also being very good. Hens of these colours were the worst of the Game classes. *Hamburghs* were well provided for, having ten classes, and the entries much better than usual. Gold-pencil cocks were a good lot, but some of the best were not looking well, first-and-cup a bird of last year, perfect in all respects, but rather small; second a large bird, but scarcely as good in tail. Of hens there were but three, but the winners good. The birds noticed in Silver-pencilled were of striking quality, colour and marking on the tails being most extraordinary. Hens also good, the competition close, and pencilling of some very fine. Gold-spangled cocks all noticed—a keen contest, especially for first position, between Messrs. Duckworth's and Mr. Beldon's old birds, there being little for choice. Hens also very good, and little to choose in point of excellence. In Silver-spangles a grand old cock stood first; a smaller bird which was beautifully marked being second, and the class very good. In hens were two of the best we have ever seen, the shape and size of spangling, colour, and evenness can, we think, never be surpassed. Black Hamburghs have lost all their coarseness, and there is little tendency to the white faces. In cocks was a gem, a bird in fact without fault, and the whole class was noticed. Hens also fine in all respects, the feathers on the winners laying almost like glass on their backs; the best of all in other respects was left out on account of a slight brown on the wing ends. *French* were not numerous, but the winners good, the cup for several classes going to the La Flèche cock; the second in which was a good Crêve-Cœur. In hens was a grand Crêve-Cœur, possessing such a head as is rarely seen; second was La Flèche. In Any other variety of poultry Mr. Walker dropped upon the exhibitors with a large Turkey cock; the second being a White Malay. This order being reversed in hens. The Local classes produced some good birds, the winners in fact being quite equal to the rest of the classes. The Selling classes were large, some very good birds being shown, Spanish winning the first in both classes. Next came the *Bantams*, nine classes, and the entries good; cock, Black or Brown Red Game very good, the winners Black Reds, good in style and true to colour; many of the others of this colour having the objectionable brown shaft in the tail feathers; and Mr. Entwisle's unequalled Brown Red very highly commended was looking very slack and open in feather. Hens, a perfect Black Red, and an almost equal Brown Red, and others very good. Black or White Rose-combed were moderate, in cocks Blacks first and second; and White extra second. Hens were a class such as we do not recollect to have seen before, being almost uniformly perfect, the first going to a grand White; and second to a Black, very small and unusually good in style. Duckwing or Pile were also very good, and almost all noticed, the first and cup for Bantams going to a capital Duckwing; and second to a Pile of good style and colour. In hens the first was a Pile, which left nothing to be desired; second also a Pile, fell little short of this one. There were two classes for other varieties, in which Silver Sebrights were the winners, except in one case, which was a Golden hen second; these were very good in all points. In the Local class for Bantams the winners were very good. One arrangement we ought not to omit—viz., a strand of rope strung on poles in front of all the pens, thus keeping back the eager crowd and facilitating the judging and putting on of the prize cards.

Of PIGEONS were equally good entries, and the awards well made, the only hitch being in our opinion that more pens did not receive notice at the hands of the Judges. *Carriers* were good in both classes, and the cup won by a capital Black cock. In *Pouters* Mr. Harvey's Blue was a clear win; Mr. Horner coming second also with a good Blue. In Any other colour the winners were Whites. *Tumblers* were good, Almond winning; Messrs. Yardley's champion and Mr. Townson's grand Agate being unnoticed. *Barbs*, Black first and Red second. In foreign *Owls* first was White and Blue second, the latter one of the smallest yet seen. English Owls were first a young Silver, a good selection; and second and third Blues. *Fantails* very good; as also the *Turbits*, in which Red was first, and Blue second, and third a Yellow Shell-crown. *Magpies* a good class; as also the *Nuns*. In *Dragoons* the first was the well-known Blue so frequent a winner of late, and this was also awarded the cup; one second and three thirds being given; thirty-four birds in the class. In Dragoons any other colour three of the winners were Yellows and one White. *Jacobins* good in all respects, the usual winners being left out. *Antwerps* a good mixed class, the first-and-cup a Silver Medium-faced bird was very good; second Short-faced Silver; and third also Silver Short-faced. Birds for flying purposes were good, and the winners well selected.

Of RABBITS we were surprised to find a small entry, but these were well judged; the prizes generally falling, as has been the rule of late, except in the case of the Dutch, where Mr. Hudson's Grey and Black were reversed. The quality was very good.

DUCKS.—*Aylesbury.*—1, C Holt, Rochdale. 2, J. Walker, Rochdale. *hc*, J. Walker; J. Hedges, Aylesbury. *Rouen.*—1, T. Wakefield, Golbourne, Newton-le-Willows. 2, J. Newton, Silsden. *hc*, J. Walker; T. Wakefield. *c*, J. E. Pardey, Newton-le-Willows. *Any other variety.*—Cup, 1, and *hc*, J. Walker. 2, A. & W. H. Silvester, Sheffield.

COCHIN-CHINA.—*Buff or Cinnamon.—Cock.*—1, W. A. Taylor, Manchester. 2 and *vhc*, J. Walker. *hc*, E. Allsopp, Worcester; W. A. Taylor; J. Royle, Manchester. *Hen*—Cup, 1, and 2, W. A. Taylor. *vhc*, J. Walker. *hc*, W. H. Crabtree, Levenshulme; J. Royle, Manchester. *c*, J. Royle (2).

COCHINS.—*Partridge or White.—Cock*—1, J. Royle. 2, W. A. Taylor. *hc*, J. Walker; H. Lacy, Hebden Bridge; L. Clark, Cheadle, Hulme; T. Aspden, Church; W. H. Crabtree; W. Whitworth, jun., Longsight, Manchester; W. A. Taylor. *Hen.*—1, W Whitworth, jun. 2, W. A. Taylor. *hc*, T. Aspden; T. Stretch, Ormskirk; W. A Taylor. *c*, H. Lacy.

COCHINS.—*Black or Cuckoo.—Cock.*—1, J. Walker 2, G. Forty, Shrawardine, Shrewsbury. *hc*, G. W. Hibbert, Godley, Manchester; W. Whitworth, jun. *c*, T. Aspden. *Hen*—1, N. Cook, Chowbent. 2, W. G. Holt, Stanhill, Oswaldtwistle. *hc*, J Walker; T. Aspden (2).

BRAHMAS.—*Cock.*—1 and 2, F. Ansdell. 3, J. F. Smith, Cherry Mount, Sheffield 4, W. H. Crabtree. *hc*, J. Finchett, Llanerst; T. F. Ansdell; J. F. Smith; G Maples, jun., Wavertree, Liverpool; W. Whiteley, Sheffield. *c*, J. Lyon, St. Helen's; A. Bamford, Middleton; J. H. Picklea, Formby, Liverpool. *Hen.*—1, T. F. Ansdell. 2 and 4, J. H. Pickles. 3, C. Holt. *hc*, Rev. A. G. Brooke, Shrewsbury; T. F. Ansdell; J. F. Smith, Sheffield; W. H. Crabtree. *c*, B. B. Glover, Newton-le-Willows; A. Crossley, Todmorden.

DORKINGS.—*Cock.*—1, J. Walker. 2, W. H. King, Sandfield, Rochdale. *hc*, D. Gellatly, Meigle; T. W. L. Hind, Kendal; H. Feast, Swansea. *c*, J. H. Pickles. *Hen.*—1 and 2, J. Walker. The whole class highly commended.

SPANISH.—*Black.—Cock.*—1 and 2, H. Beldon, Goitstock, Bingley. *vhc*, J. Boulton, Bristol. *hc*, E Allsopp, Worcester; J. Walker, Wolverhampton; R. Newbitt, Epworth. *c*, J Powell, Bradford *Hen*—1, R. Newbitt. 2, J. Powell, Bradford. *vhc*, J. F. Sillitoe, Wolverhampton. *hc*, J. Clews, Walsall; E. Allsopp; J. Thresh, Bradford; J. Bantams.—*Any other variety.*—*Cock*—1, A. Greenhalgh, Huncoat. 2, N. Cook, Chowbent. *hc*, A. & W. H. Silvester; T. P. Carver. *Hen.*—1, N. Cook. 2, T. Fell, Blackburn. *hc*, J. Walker; N. Cook; A. & W. H. Silvester; T. P. Carver.

Bantams.—*Local Class.*—*Cock.*—1, G. Birtwistle & T. Whittaker, Haslingden. 2 and *hc*, E. Walton.

PIGEONS.

Carriers.—*Cock.*—Cup, P. R. Spencer, Hereford. 2, H. Yardley, Birmingham. *hc*, J. Walker; E Horner (2). *Hen.*—1, W. Nottage, Northampton. 2, P. R. Spencer. *hc*, J. Walker; E. Horner.

Pouters.—*Blue or Black.*—1, W. Harvey, Sheffield. 2, E. Horner. *hc*, J. Hairsine, Hull. *c*, W. Nottage; P. R. Spencer. *Any other colour.*—1, L. & W. Watkin, Northampton. 2, W. Harvey.

Tumblers.—1, J. Gardner, Preston. 2, W. Brydone, Dunse. *hc*, E. Horner. *c*, T. Kirby, Rochdale.

Barbs.—1, H. Yardley. 2, J. Stanley. *hc*, J. Walker; E. Horner (2).

Owls—*Foreign.*—1, T. W. Townson, Bowdon. 2 and *hc*, T. Kirby, Rochdale. *English.*—Cup, T. W. Townson. 2, J. Gardner, Preston. 3, T. Charnley, Blackburn.

Fantails.—1, J. Walker, Newark. 2, T. S. Stephenson, Newbiggin, Beverley. 3, W. J. Warhurst, Stalybridge. *hc*, W. Lumb, Rochdale.

Turbits.—1, T. W. Townson. 2, T. S. Stephenson. 3, W. Brydone. *hc*, H. Yardley; E. Horner (2).

Magpies.—1, E. Horner. 2, J. Richmond, Oswaldtwistle. *hc*, M. Ord, Sands, Sedgefield.

Nuns—1, J. B. Bowdon. 2, E. Horner. *hc*, J. Richmond; E. Horner.

Dragoons—*Blue or Silver.*—Cup, R. Woods, Mansfield. 2, R. White, Manchester. 3, R. Woods. Extra 3, F. Eastwood, Littleborough; R. Woods. *hc*, W. Smith, Walton, Liverpool; J. Holland, Manchester. *Any other variety*—J. J. Stanley, Blackburn. 2, F. Graham, Birkenhead. 3, R. Woods; J. Holland. *hc*, T. Charnley; F. Woodhouse.

Jacobins.—1, W. Brydone. 2, G. Richardson, Oulder, Rochdale. 3, W. Lumb. *hc*, S. Lawson; J. Richmond; E. Horner.

Antwerps.—Cup, F. Eastwood. 2, R. Brierley, Bury. 3, W. Harrison, Burnley; W. Harvey. *hc*, H. Yardley; J. Wright, Manchester. *c*, J. Stanley; A. Bingham, Manchester.

Birds for Flying Purposes.—1, J. Wright 2, T. H. Holden, Haslingden. Extra 3, B. Rawnsley, Bingley (2). *hc*, R. Brierley.

Any other Variety.—1, W. Harvey. 2, T. W. Townson. *hc*, J. B. Bowdon; A. & W. H. Silvester. *c*, A. & W. H. Silvester.

Local Class.—*Any variety.*—1, G. Fielding, jun., Haslingden. 2, J. S. Titherington, Haslingden.

Selling Class.—1, J. B. Bowdon. 2, W. Dugdale, Burnley. *hc*, W. Brydone. *c*, R. Brierley.

RABBITS.

Lop-eared.—*Buck*—1, A. Hudson, Hull. 2, T. Schofield, jun, Cheetham. *vhc*. Mrs H. Duckworth, Spalding. *Doe.*—Cup and 2, J. Irving, Blackburn. *hc*, T. Schofield; A. Hudson.

Angora.—*Buck or Doe*—1, A. Atkinson, Huddersfield. 2, J. Orden.

Himalayan.—*Buck or Doe.*—2, A. Atkinson. *hc*, J. G. Meadowcroft, Rochdale; B. Hopkinson, Fishpool, Bury. *c*, R H. Greenwood, Rochdale.

Silver-Grey.—*Buck or Doe*—1 and *hc*, A. Hudson. 2, Miss Mortimer, Reed-Hall, Ross.

Any other Variety.—*Buck or Doe.*—1, A. Hudson. 2, J. E. Pilgrim. *hc*, J. Irving; A. Hudson.

Selling Class.—*Buck or Doe.*—1, A. Simpson, Rochdale. 2, J. Ogden.

Judges.—*Poultry:* Mr. Hutton, Pudsey. *Pigeons:* Capt. Heaton, Worsley. *Rabbits:* Mr. J. Boyle, jun., Blackburn.

BEES IN A CHIMNEY—INTRUSIVE LETTERS.

"W. J. M." asks how a swarm can be expelled from a chimney very difficult of access? It is very difficult either to expel or hive a swarm from a chimney. If a hive of combs could be placed within a few feet of the swarm before the bees commence to build combs of their own they would readily take to combs, but after they have commenced to build they would not leave their own combs for those in the hive. In the attempts to hive swarms in chimneys there are the difficulties of ascent, the risk of being well stung, and the uncertainty of success after all. Smoke from corduroy or tobacco will disperse the bees somewhat for a little while, but will not dispel them.

If "W. J. M." wishes to take the bees alive out of their present position, we would advise him to throw a wet sack over the top of the chimney with a view to bring them all down on to a sheet spread over the grate by chloroform or puff-ball. If the powers of either of these can be applied to the bees they will fall down the chimney with all their powers paralysed, and may be gathered into a hive before they recover their senses and activity. Afterwards the bees would naturally fly back to the chimney, and they might induce the queen to go with them; hence in hiving a swarm from a chimney it is desirable to send the swarm to a distance of two miles for a week or two. If "W. J. M." wishes merely to clean his chimney, and cares nothing about preserving the lives of the bees, he could destroy them by casting a wet sack over the top of the chimney, and applying the fumes of brimstone from below. By leaving them where they are for two or three months he might obtain all the honey they may gather. If any of the combs remain in the chimney after the bees shall be expelled, they would attract another swarm.

The hive where the bees are hanging out but still without drones is all right and will swarm. The absence of drones is simply an indication that the hive has very little drone-comb in it, or what little it has is filled with honey. The absence of drones is rather a favourable symptom than otherwise.

Will the readers of this Journal please to remember that I have not time to answer private communications? From twenty to thirty letters of inquiry every week are being sent to me. If many of the letters were answered through the columns of this Journal hundreds of readers would derive the benefits of the answers as well as the parties putting the questions. My time is fully engaged with my business, and it would take a clerk half his time to answer all the letters received here.—A. Pettigrew.

[Readers who write to our correspondents privately in defiance of the notice we permanently publish requesting that they will not do so, act discourteously and do as they would not like to be done by. We beg of Mr. Pettigrew and of all of our other correspondents that they will never reply to such intrusive letters. All applications for information should come to our office.—Eds.]

SWARMING.

As the A B C and multiplication table have to be gone over many times before young people can fairly master them, many of the simplest lessons in bee-management have to be repeated often before beginners can fully understand them or put them in practice; and many young bee-keepers, liking example better than precept, assert that if they could only see someone else carry out the lessons, they would do them afterwards. They lack confidence in their own ability and not in the truth of the lessons taught. As we are now in the midst of the swarming season, and have so many apiarians around us seeking information, we may here help some of them by going over again ground often trod.

A lady called to ask why a first swarm of hers had issued three times, and always returned to the old hive. She had seen no queen in front of the flight-board, and said she would gladly pay for a cab to carry me to her garden if I would consent to go there and tell her why the bees always went back. Her garden was visited, when all her hives were found healthy and ready for swarming. I swarmed them artificially for her, and showed her the queen from the hive that had had three miscarriages in swarming. Why the queen declined to go with the swarm three times in succession is very unusual, but no one can account for her refusal.

Another lady writes to ask why her swarm left a new hive after it had been in it four or five hours. Bees have likes and dislikes, whims and fancies, which no one can explain. We have had a swarm so fastidious and whimsical that it would settle in no hive we could give it. It forsook three new hives in twenty-four hours, became fugitive at last, and was lost.

"Two queens went with my first swarm," says one correspondent; and another says, "My bees piped this year before they swarmed. How is this to be accounted for?" In both cases the hives had lost their old queens and had bred young queens. When these came to perfection the bees swarmed, as in the case of second swarms. Two young queens sometimes go with second swarms. Queens twelve months old never pipe before swarming. So far as the present season has gone bees swarm readily. In many cases they have set queens and swarmed before they were well filled, and in almost all cases second swarms are sent off at the proper time afterwards. Some seasons bees seem to hesitate a long time about swarming, and many hives never swarm at all. Some seasons are remarkable for the abundance of swarms. First and second, and in some instances third, swarms issue readily, and in such seasons early first swarms send off virgin swarms.

The readers of the *Journal of Horticulture* are aware that for profit from bees, and to possess and keep the apiary full of strong healthy hives, I prefer the swarming mode of management to any other; but many bee-keepers prefer the non-swarming system. We take all the first swarms we can till the end of

June. In ordinary seasons they fill their hives, and many of them fill supers as well. Most of them become too heavy for stocks—that is to say, are too well filled with honey for keeping. Hives beyond 80 lbs. each are put down for honey. Those beyond 60 lbs. yield to the comb-knife 10 to 15 lbs. of honeycomb each, and make stock hives afterwards. In favourable seasons for honey almost all the first swarms become too full of honey for keeping. Hives in which the bees have been fed during the winter months, and with 20 or 30 lbs. to spare in spring, do not yield large swarms, but the honey in them is as good the second year as it is the first.

Second swarms or casts are taken from all stock hives that swarm in May. These make excellent stocks for another year, and their mother hives become quite strong enough without them. If second swarms are not taken from early swarms they become too heavy for stocks, even if supers be filled on them. From late swarmers we do not take second swarms; but when they are heavy at the swarming season the bees are generally turned out of them into empty hives three weeks after they swarm, and the honey taken from them. Sometimes the bees are driven ont of light swarmers or stocks as soon as their queens are hatched, into empty hives, and re-peopled by later first swarms before their brood cools. The queens of first swarms are then laying so many eggs that the combs of the hives thus re-peopled are filled at once with brood, and continne to be filled with brood till the end of the season. The reader will at once see that this stratagem gives a great lift to late swarms, pntting them on a par with earlier swarms.

Some six weeks or two months ago we expressed our fears that many hives would this season be affected with foul brood, the very cold weather of March having been of such a chilling character. We have lately smelt foul brood in several stock hives. Hives affected with this disease can never prosper or be cured. As soon as they can yield moderately-sized swarms they should be made artificially and put into empty hives, for small swarms will do better in empty hives than all the bees would do amongst the foul brood. All the bees of course could and should be removed from foul hives three weeks after their first swarms. Swarms from foul hives do not carry the disease with them. By the swarming system of management the apiarian may stamp out this terrible disease from his apiary, and stamp it out by increasing the number of his stocks and taking the honey from all his affected hives.

Three days ago we swarmed two hives artificially standing together. The bees of one of the stocks commenced to set queens as soon as the swarm was taken from it; the bees of one of the others remained in a state of grief and commotion for more than two days, searching hither and thither for their lost queen before they began to set eggs in royal cells. I have never witnessed greater consternation and commotion among bees bereft of their queen that had eggs to set. To-day they set eggs in royal cells. No one can tell why the bees of the one hive acted so differently from those of the other.

Yesterday I saw a second swarm begin to issue from a hive when I went near to watch the queen come out. She was nearly the last bee in the swarm to leave the mother hive. While the queen was on the flight-board a worker intentionally caught her by a leg, but whether the bee meant to say "good-bye" or "don't go" no one can tell. I put two young queens and a second swarm into an empty hive. In about five minutes afterwards the queens met and fought. It was a short but fatal battle, for one of them was mortally wounded in a twinkling, and almost dead before her victorious and triumphant sister was scared off by my hand put forth to save her.—A. Pettigrew.

OUR LETTER BOX.

Crowle Show.—Our reporter omitted to notice that Mr. W. Whitworth, jun., obtained a first and special prize for White Cochins, and second prize for Houdans; and that Mr. W. H. Crabtree obtained a second prize for Dorkings, first for Light Brahmas, third for Dark Brahmas, and highly commended for Crêve-Cœurs.

Dari.—Miss E. W. Bireley, Telegraph House, Great Yarmouth, wishes to know where she can procure Dari for her poultry.

Bone Meal (*W. Hayser*).—It is chiefly used mixed with food for chickens. The phosphate of lime in the meal is believed to promote the formation of bones and feathers.

Driven Bees (*Triceps*).—We think you drove the queen with the bees into the bottom hive, which, if we understand you rightly, acts as a nadir. The use of nadirs very often, but not always, do prevent swarming. A few dozens of dead bees around a hive may often be seen when all in it is going on healthily.

Hives (*T. R., near Birmingham*).—The hives you refer to are made of straw in a dry state and split canes. During both summer and winter they should be covered sufficiently to protect them from rain. Swarms put into empty hives in September may be well and rapidly fed, and thus made into strong stocks, well able to live over the winter. The bee-keepers in your neighbourhood, or any other who kill their bees to get the honey, have a lesson or two to learn.

Preventino Swarming (*A Novice*).—No kind of hive prevents swarming. Bees naturally swarm when their houses, whatever be their structure or shape, become full. But generally speaking they may be kept from swarming by enlarging their houses from below—that is to say, by eking or adding to their hives, and thus making them one-third or fourth larger at a time. In favourable years for honey several such ekes may be required, and it is better and safer to apply them before the hives are overcrowded.

Crested Norwich Canary.—"I notice under the heading of 'Our Letter Box' in last week's Journal Mr. W. B. Hovell, of Norwich, says:—'Mr. Geo. J. Barnesby is not correct in his description of fig. 92 when he says Messrs. G. & J. Mackley's Crested bird was the bird which took first prize last year at the Crystal Palace Show.' Mr. Hovell certainly charges me with an assertion I never made, and which charge is not true. Upon referring to p. 381 of the Journal Mr. Hovell will find that what I stated was that 'the specimen shown by Messrs. G. & J. Mackley, Norwich, in Class 13 (No. 437), at the last Crystal Palace Show, stood at the head of forty-eight others.' This assertion I repeat. As to the bird's performances, and whether the same bird did or did not take first or second at Yarmouth or Lowestoft, is quite immaterial so far as I am concerned. I beg to enclose Messrs. Mackley's letter (not a private one to me, as the contents were for publication), stating where and what prizes their Crested bird had won, and upon the faith of which letter I remarked.—G. J. Barnesby."

REMARKS.

9th.—Fine early; but stormlike by noon; frequent thunder after 2.30 P.M., but neither near nor loud; the evening cool and pleasant.

10th.—Cloudy and rainlike all day; frequent slight showers, one heavy one, but of short duration, about 5 P.M.; fair night.

11th.—Fine at 9 A.M.; but nearly half an inch of rain had fallen in the early morning; very windy, with showers, during the day; but fine at night.

12th.—Fine but cloudy early; showery all the after part of the day. The rain at times rather heavy.

13th.—Rain more or less all day, sometimes heavy.

14th.—Very windy, with frequent showers; warmer towards night.

15th.—Still very windy and showery, the wind at times unusually high for the time of year, but much brighter than it has been for several days.

The mean temperatures, except that under ground, and the shade maximum about 4° below last week; the former fell 1° only, and the latter 12°. Very windy and much rain.—G. J. Symons.

COVENT GARDEN MARKET.—June 16.

We are now getting rather heavily supplied with outdoor produce, and also from the Continent, but as the Kent goods now comprise Early White Cherries and Dukes from standards, we must expect a diminution in the consignments. With some sunny weather we may expect in a few days large quantities of Strawberries from the adjacent parts of London. Potatoes maintain last week's rates.

From observations taken near London during forty-three years, the average day temperature of the week is 73.4°; and its night temperature 48 8°.

SEMI-NATURAL FLOWER GARDENING.

SOME writers go into raptures about "the pathless woods." They are certainly very enjoyable on a hot summer's day, provided the underwood is not too thick; but I think one of the most enjoyable spots on earth is that which is half wood, half shrubbery, carpeted with low-growing plants prodncing a succession of flowers through the four seasons, and with a well-drained walk, not too trimly kept, but such as can be used in all weathers, where there are gigantic timber trees to shelter from sun or rain, and rustic seats at intervals on which to rest while listening to the music of the birds and inhaling the odours of the flowers. If ever I make a spring garden in accordance with my own ideas it will be in such a spot as this; aye, and my summer, autumn, and winter gardens shall be there too, for I will have a perpetual succession of flowers from the Winter Aconite to the Christmas Rose—not in ribbon borders and carpet patterns, but in humble imitation of Nature's own sweet ways. I have never yet seen a spring garden that I thought even worth calling pretty; I have not seen many, it is true, but I do not think it possible for Daisies, Primroses, and such-like plants to look well in straight lines and formal beds: they have such an uncomfortable look, as if conscious of being out of their proper place, and cut about as sorry a figure as I should expect a journeyman chimneysweep to do at Her Majesty's Drawing-room.

The handsomest of deciduous underwood is, I think, the Hazel. One peep where the plants are rather thin gives you a sight of the Grape Hyacinth, studded like jewels in the green of the Dog Mercury reaching away far into the wood, and ending you know not where. So much the better, the imagination can do the rest. A little further on are Primroses by the acre, and yet there is not a plant too many; place a fourth of that quantity anywhere else but in a wood, and you would not care to look at them a second time. There are other grand masses composed of such things as the Wood Anemone, the Foxglove, Bugloss, &c.; these are perfect in themselves and cannot be improved on, the only thing to do is to take care they are not too much hid by the underwood; they are better for being partially hid—beauty is best appreciated when it is half veiled.

But there are spots near the walk where there are plants of an objectionable nature, or where the ground is altogether bare, and filling these with appropriate plants is most interesting, and perhaps requires a greater amount of taste than any other kind of ornamental gardening, unless it be the planting of large-growing trees. We are so apt to overdo it. It is very little that is required, and I should advise anyone who is not an adept at tree art to do that little very gradually indeed. Every existing feature should be turned to good account. Do not make any great changes without thinking the matter over many times in different moods of mind. We are not always in the right mood for arranging things of this sort. The poetic part of our nature will not always come forward to order; we must wait, and not attempt to force it. Perhaps some fine morning, if we rise at the same time as the cuckoo does, and take a walk to the spot before we face the dozens of failures and vexations we are sure to meet with in the garden, the happiest of thoughts will flash across our mind, and the note-book is all that is required.

Too much formality must be avoided, but the thought has often struck me what a very little removed from regular lines are our best landscape effects. In trying to make new planting appear natural we are apt to make it too irregular; and it is the same in making rockwork and other imitations of Nature. A certain amount of ruggedness gives grandeur, as does the discordant seventh in a musical arrangement when judiciously introduced, but repeat that discordant combination too frequently, and it has anything but a grand effect.

There are many handsome plants which will take care of themselves as well as do the commonest weeds, and which may be introduced into our shrubberies and woodland walks, adding a great charm to them, and yet looking so natural that anyone not well acquainted with plants might think they were wild. This is the very object to aim at. The greatest art lies in concealing art. If I am asked concerning a plant, or a mass of plants, which has only been in position a year or two, "Did you plant that, or was it always there?" I feel it is the greatest compliment I can receive on the score of good taste.

Have you a spot where nothing will grow—say stiff clay, and very much shaded? That is the place for Tussilago fragrans; it is nearly always green, and has flowers in winter scented like May blossom. The Periwinkles are all handsome and will take care of themselves; the larger green-leaved species, Vinca major, will overrun most weeds, and kill them in time. Its variegated variety (V. major variegata, syn. elegantissima) is equally hardy, and is one of the handsomest variegated plants we have. V. minor, V. minor alba, and V. minor variegata are all useful; these are not so robust as the first named.

There is a bank shaded but not overhung with trees—the very place for British and North American Ferns. If the soil is too heavy the plants must be merely placed on the top of it, and surrounded with some of the leaf mould to be found in the neighbouring hollow. Near by is a handsome Rhododendron, very attractive while in flower, but rather dull-looking in autumn; we must light this spot up by placing a Torch plant (Tritoma) in front of it. The Tritoma looks handsome as a specimen on the grass, but to see it in perfection it must be backed by a dense green bush. T. uvaria glaucescens flowers in September; T. grandis and other varieties a month or two later. Russian Violets must not be forgotten for flowering in the winter: I think the old small variety is the hardiest. I have tried The Czar for this purpose, but it did not answer my expectations.

Climbing Briars are very handsome, finding their own

way up the stems of old trees, and hanging in natural wreaths from the branches. Gloire de Dijon Rose may also be used for this purpose, as also may Honeysuckles and the gorgeous Clematis; while for carpeting there are Golden Thyme, Stachys, Musk, St. John's Wort, London Pride, variegated Coltsfoot, &c. Specimens may include Spiræas, Fuchsia Riccartoni and others, Anemone vitifolia and Honorine Jobert, Martagon and other Lilies, and Pæonies. Bulbs, too, will make a pleasing feature, and may include Snowdrops, Snowflakes, Daffodils, Narciseus, and Jonquils.

One thing I recommend specially to be avoided in all shrubberies, that is not to plant flowers in continuous lines along the edges of shrubs, as was very commonly done in the London parks a few years since; but plant in irregular masses between and outside of the shrubs, covering all the soil so that not a particle of it is visible. If turf is used between the shrubs and the walk it should not be cut to a line next to the shrubs, but should lose itself in them.

Deciduous shrubs should not be trimmed up to look like an exhibition Azalea, but when too thick some should be cut clean out, or at least so managed that they will not show they have been cut. Evergreen shrubs are not so objectionable-looking when cut in shape, but even these should not be trimmed too much.—William Taylor.

LATE PEAS.

Seed sown at once will produce a crop of Peas in the autumn, and a most valuable crop it is. For some years I have in the north of England gathered Peas throughout November from seed sown from the 20th to the 27th of June in each year, and I know of no crop which has been more serviceable and more prized. Owing to hot weather there is generally a dearth of Green Peas towards the autumn; the plants, when in bloom and podding, cannot sustain the drought, but in a younger state they may be carried through, and will swell to perfection with the autumn rains. Three things must be borne in mind in preparing for this latest crop—viz., a hardy vigorous sort must be selected, the seed must be sown in trenches, and several rows must be sown at the same time.

The sort I have found the best for late autumn use is Ne Plus Ultra. It resists mildew, is a continuous grower and podder, and is of good quality. Other sorts will produce Peas in the autumn; but I have found none in all respects so good as this fine old sort. It sets its flowers well in wet weather, and is of good flavour, even if the haulm is browned by frost. As a dwarf variety Hair's Mammoth is good for late use; but where sticks are plentiful I commend Ne Plus Ultra. In October, if growing very vigorously, it is advisable to pinch-off the tips of the growth, for at that season the late flowers cannot perfect peas, and the lower pods will be accelerated in the swelling.

They must be sown in trenches, or they may languish in the tropical weather of July and August. If on the level it is impossible to give them sufficient water, but if in trenches it is easy to give a thorough deluge once a week. The trenches should be as wide apart as possible, and be dug-out much the same as for Celery, and have some manure dug-in deeply. If the rows are close together the flowers will not set in the autumn, for the haulm then grows exuberantly, and is long-jointed and sparse of bloom if lacking air. Rows of Ne Plus Ultra for this latest sowing should be 8 feet apart.

A large breadth should be sown. It must be remembered that there can be no succession to this sowing, and that the crop itself will not bear a third of the produce it would if sown in February or March. The crop will yield its own succession so long as open weather continues. I have in an exceptional season gathered from the same rows in October and in December. Suppose three rows to be sufficient in the ordinary Pea season, nine rows will be necessary to give ample gatherings so late as this crop will be. But what of the ground? Well, it is generally as easy to find ground for nine rows now as for three rows in March or April. Rows of early Potatoes can be taken out where the Peas are required, or the Cabbage or late Broccoli ground is vacant.

Perhaps the early Potatoes may not be sufficiently ripe to dig up by whole rows at a time for table use, but they are ripe enough for seed. These unripe Potatoes make the very best of seed. I cannot say why it is, but many years' experience enables me to vouch for the fact that Potatoes which are taken up when in an unripe state will yield crops fully as early and quite as heavy as will those which had been left in the ground to become matured. In fact, I have found after repeated trials that the unripe seed is the best. It is also the only means I know of resisting the disease.

Now, if an abundance of Green Peas can be produced in the late autumn months, and at the same time a supply of sound early Potatoes are provided for planting, the work is surely recommendable. Every fourth row of Potatoes taken up and the ground thoroughly soaked with liquid manure—say guano water of a strength of 1 to 2 ozs. per gallon—will afford space sufficiently enriched for the growth of Peas. This plan is merely suggested as affording room for the Peas when other ground is not vacant, and because the practice has been tried and has answered well. By the time this late crop of Peas requires support sticks from the earlier crops will be at liberty, and only need to be removed from the dying rows to those which are in full and vigorous growth. The early sorts of Peas are often sown at this season, and occasionally yield useful produce; but should a term of tropical weather set in when they are 6 inches high it is almost impossible to prevent them from flowering, and their produce is then neither late nor bountiful. Marrows, and especially the sort named, will, on the other hand, pass through the drought under which weaker sorts succumb, and will give a supply of Peas of good quality even when the rows are white by frost.

Occasionally an early and severe frost has spoiled a quantity of Peas on these late rows; but more than once I have been sufficiently wide awake to gather them on the approach of danger, and by sticking the full pods closely together in wet sand and out of the reach of frost the Peas have been kept for a fortnight as fresh and good as if growing on the haulm. By that means I have been enabled to supply an occasional dish of excellent Peas when the ground has been covered with 6 inches of snow, and once to a dinner party where the guests had sharpened their appetites by an afternoon's skating on the lake. The verdict was that this dish of Peas was decidedly late and undoubtedly good. They were Ne Plus Ultras.—A Northern Gardener.

BUTTON-HOLE ROSES.

Before answering the query of "H. M. H." I must make a few observations. For button-holes I think handsome buds with fine sepals and good foliage, or partially expanded Roses of the globular form, are best. In hot weather expanded Roses, if the petals are flimsy, will soon be withered. We want more silica (flint) in our petals. Moss Roses are best in their unexpanded form, for when fully expanded they lose their mossy character. I will give a list of Roses suitable for the purpose among the summer and autumnal Roses.

Summer Roses.—Moss, Common Moss, the Created, and Vandsë.

Variegated Roses.—Œillet Parfait, Madeleine, and Tricolore de Flandres. These must be expanded to see their beauty.

The following Roses should be only partially open—Coupe d'Hébé and White Provence.

Autumnal Roses.—These should be in bud form, or only partially expanded. Jules Margottin, fine sepals; Madame C. Joigneaux, Claude Levet, most beautiful red-currant crimson and nicely scented, which is not the case with Etienne Levet, which is otherwise very good. The next are in the line of yellow, and are good; Maréchal Niel, Gloire de Dijon, Céline Forestier, and Triomphe de Rennes. The above are best for the purpose when only partially open.

Tea Roses.—Devoniensis, Souvenir d'Elise Vardon, and Madame Willermoz.

Bourbon.—Souvenir de la Malmaison, best in the autumn. The following Hybrid Perpetuals may be expanded fully:—Charles Lefebvre, Sénateur Vaisse, Madame Victor Verdier, Cécile de Chabrillant, Duke of Edinburgh, and Marguerite de St. Amand. Madame Knorr is most beautiful in bud form. The next lot are high-coloured, varying from crimson purple to maroon, and should be expanded when used for the button-hole. They are beautiful. The two first I name are new and admirable Roses, both by E. Verdier—John Harrison, Theodore Buchelet; Abbé Bramerel, Maxime de la Rocheterie, Baron Chaurand, most beautiful; and Dr. Jamain, very beautiful. The next is a new Rose, fiery crimson, good, and good for the purpose when fully expanded—Firebrand (W. Paul).

I regret that some of our late and good Roses have no scent. I thank Mr. Camm for calling attention to that excellent quality, in which the Bourbons and China Roses are deficient. Souvenir de la Malmaison is the only scentless Rose named above.

Lamarque is the finest scented, and Goubault the most peculiar in its scent.—W. F. Radclyffe.

EXPERIMENTS IN STRAWBERRY CULTURE.

It is well known that the young Strawberry plant will thrust its roots into the hardest soil—*i.e.*, a garden walk, in which it especially seems to luxuriate. I placed thick squares of turf 9 by 9 inches to the amount of several hundreds on the Strawberry beds, and three good runners on each turf. By the end of the season these plants were as large as those of a year old. These were planted out at the usual distance, and are now equal to plants of two or three years old, and bearing a crop quite equal to those of that age. As there were more plants than were required, several were left lying about on the surface, and were not planted out till late this spring. This late planting has not at all retarded their growth or lessened the crop. About the middle of March some of these plants that had been lying about were brought into the hothouse, and ripened a very fine crop of Sir J. Paxton.

For forcing there is no occasion to pot these plants, they will grow as well on boards if treated thus: Cover the boards with a layer of turf, grass side downwards, free from wireworm (which can be effected by scalding), on this turf place some rotten dung, and then the square of turf with the plants on the top of this. They may be grown in Vine borders if placed close to the glass. By the above plan Strawberries may be grown on fresh land every year to great advantage.—Observer.

AURICULA SHOWING.

The letters which have appeared on this subject have especially interested one who looks back to the time when the Auricula held as high a place in the estimation of metropolitan florists as it seems now to do with our northern friends; when good old John Dickson of Acre Lane was in full force, and amateurs who have long since passed away or retired from active service used to throng the tables at "The Horns" and the Surrey Gardens; and if any of them had been told that the day would come when their beloved favourite should be allowed to go with a wooden crutch, or a plant with three or four trusses of bloom be considered "the thing," they would have opened their eyes with astonishment. As a disciple of (in florists' flowers) George Glenny, and as an unworthy successor of the amateurs I speak of, I must side with Mr. Horner in the view he has taken on page 448, and indeed in the different views held by north or south I hold in many points with the northerners. I maintain that above all things refinement is the quality for which the Auricula grower should win. I know it requires good moral courage to maintain this when large and most vigorous plants throw your smaller ones into the shade, and when in the eyes of nineteen-twentieths of the visitors these are unquestionably regarded as the best. And here let me distinctly state that in saying this I do not for one moment mean to maintain that I had any chance this year in our metropolitan exhibition. I was never worse off; all my best plants were not in bloom, and some of those that were shown had been kept too close in order to get them in. I had one plant which I regarded as a true sample of my collection. It took the first prize in grey edges; it was small in foliage, but it was a refined plant of Richard Headly. With this exception I had not one plant that pleased me thoroughly, so I write without prejudice.

As to the number of pips, I do not hold with the northern estimate, and think that no plant should have less than five. I am not disposed to limit the number, although I believe that a plant with seven good ones is about the perfection of truss. When they go to eleven or thirteen there are always sure to be defective ones; still, if a truss of that size can be had in which the pips are all correct I quite agree with the dictum that it should have precedence. It is however, I believe, very rare to find it when measured by the strict rules of correct Auricula judging.

I cannot hold with the opinion that the Auricula should be shown with a stake. It is done in the south; I do it myself because others do, but I should be glad that it were dispensed with. It might never be required; and if a truss is top-heavy it may probably be an indication that it had better not be quite so large. We have in our Society made a rule against more than one truss. I fear "An Old Fancier" will, alas! yet see his rule against stakes rejected. Auricula growers in the south will have to be educated to it.

I do not agree with the prejudice that some of the northern growers have against violet or lilac body colour, and where it is associated with other qualities the prejudice ought to be overcome. What more beautiful than a well-bloomed plant of Maria? I know it has a poor tube, but so have many flowers that hold a good place, but what a lovely colour it is! Col. Champneys is without doubt a very striking flower but a very defective one, yet will it always down south throw others into the shade, which, although not so brilliant, are yet more refined. The tube is washy, the colour too deeply laid on, and the pip too cupped; but what a grower it is, and how showy on the home stage! but who for a moment would place it in the same category as George Lightbody, or Richard Headly, or Robert Traill? By-the-by, both Mr. Douglas and Mr. Horner speak of flowers with this blue, lilac, or violet body colour as if they were called by the Lancashire growers *chancy*. I thought it was *chancy*, a corruption of china, used in derision on account of their various colours, like a piece of coloured chinaware.

All these discussions on the subject of the Auricula make me hopeful of a return to the popularity that this flower once enjoyed. It is one which, as I have said, holds a strange fascination over its lovers, and I only wish that they were more numerous down in these southern regions.—D., *Deal*.

AUTUMN-SOWN ONIONS.

What is the best Onion for autumn sowing and early spring use? My attention has been drawn to this subject by Mr. Luckhurst in the Journal, page 404, of May the 27th. It led me to examine my own plot of autumn-sown Onions, which include Globe Tripoli, Flat Tripoli, and last, but not least (this is not the Queen, but still it is a queen in its way, and if I might be allowed I should like to call it Silver Queen), the old Silver-skinned variety, which is usually sown for pickling purposes.

I measured one of the Silver-skinned bulbs, its circumference was 9 inches. The other kinds, comparatively speaking, were not worth any special notice; as a rule they were thick-necked, and the bulbs not very large, so that I did not measure them, but to-day (June 14th) I have done so, and the following is the result:—Globe Tripoli, 8½ inches; Flat Tripoli, 8 inches; and the Silver-skinned, 9½ inches, showing an increase of half an inch since the first measurement. This variety, I think, possesses all the good qualities desirable in an Onion. It is mild in flavour, a quick grower, thin-necked, has a small top, and is perfectly hardy.

I may state that the seeds were sown on the 14th of August, in drills 9 inches apart on a south-west border. I usually transplant in March or April, but this year I did not do so, as the plants came up rather thin in the autumn, and the spring being cold and dry I let them remain in the seed-bed, merely weeding them when they required it. Owing to the late dry weather the Silver-skinned variety is showing signs of ripening and is ready for pulling-up, while the other sorts are still growing, the Globe Tripoli being the worst in the lot, thick-necked and inclined for seeding. I do not know what induced me to sow the Silver-skinned variety in the autumn, but I have done so for the last three years with the same good results. I think this an invaluable variety. I have not seen anything in the market this season to equal it.

I do not know anything of the Queen Onion, but from the description given by Mr. Luckhurst I am quite prepared to believe it to be a good variety.

I may state that in the measurement of the bulbs of the Silver-skinned many of them were so equally balanced in size that there was some difficulty in selecting the largest, while in the other kinds no difficulty was experienced, as large bulbs were few and far between. As the Onion-sowing period is approaching I would advise the old Silver-skinned pickling and the new Silver-skinned Queen to be sown side by side.—G. R. Allis.

BORDER PLANTS—GARLAND FLOWER.

I would direct attention to Daphne cneorum, "Goddess of the Woods or Meadows," as its name implies. If not strictly speaking a spring-blooming plant, it is sometimes seen in flower under favourable circumstances during spring and early summer. It is of trailing habit—a very accommodating evergreen shrub on the rockery or in the border. With care it makes a good edging, and, what is better, if thought desirable it

can remain permanent. It may be turned to good account in various ways, being perfectly hardy. It thrives well in sandy loam and peat in equal quantities, and should have good drainage, yet should not be allowed to suffer for want of water. It is increased by division and layering during the summer. When used as an edging it requires pegging. It may be turned to good account for indoor decoration, and grafted on Daphne Mezereon grown in pots may be made to assume a weeping habit, or any shape the operator pleases. The common Spurge Laurel (Daphne Laureola) may also be used as a stock for grafting on. It might be worth the trouble to graft the three different-coloured Daphnes, Mezereums, and D. cneorum on the same stock. In my mind the white, pink, and nearly crimson, with the evergreen cneorum, would have a very good effect in a cool greenhouse during the winter and early spring, when flowers in many places are none too plentiful.—VERITAS.

THE ARRANGEMENTS OF COLOURS

IN THE BEDS OF THE LONDON PARKS AND GARDENS.—No. 2.

DESIGNS FOR FLOWER AND CARPET BEDDING ON GRASS.

THE circle is the most simple form, and when planted in harmonious proportions and tints is most pleasing. I shall now detail how to plant on the carpet-bedding mode. Various plants, a great proportion of them new, are adopted to show that the Geranium and Calceolaria are not the only candidates for popularity in the summer garden. I admit there are few plants that will look more showy than those named; nevertheless, it is desirable that others of equal brilliancy were more generally made use of. For carpet bedding plants require to be selected not only for their suitable colours but their duration and height.

I have confined myself to low-growing plants, but there is no reason why tall-growing plants should not be used, or annual or perennial flowers, also spring flowers and bulbs. A common plan is to contrast the tints of adjacent blooms, never to let blues stand close to blues nor reds be next to reds; or they might be planted on the principle of blending the colours, four or five rows to consist of various shades of the same colour. Again, a rich effect is obtained by following the order of the prism colours—having all the flowers at one end or side dark purple and violet, and at the other dark reds, the purples to be followed by blues and light porcelains till you come to white. Next the white should follow the yellows, after them pink, then full reds, then dark crimson.

I will now add a small list of annuals which I know are lasting and effective. Annuals are a beautiful and extensive tribe of plants and worthy of the best treatment, and their service is essential in most gardens. I shall therefore make a few remarks on the method of raising and their successful culture—first, hardy annuals, which stand all weathers; second, half-hardy, which can bear no frost; third, tender, which will not thrive in the open air. These divisions, however, run into one another by imperceptible gradations, for several of these rank among tender annuals yet may be planted outdoors during the summer months; and the hardy annuals are the better if treated as half-hardy, so the one treatment will suffice. Besides, transplanting is in most cases an advantage, and secures health and vigour to the plant providing it is properly done. Raise the seedlings upon a gentle hotbed, and when they are strong plants remove them to their destination; but one of the chief points in the cultivation of annuals is to have the seeds germinate well and quickly, and to have the plants into their second leaf. If the seeds are sown the fore part of April they will be ready for the beds the latter end of May; and if it is showery weather when you turn them out the plants will not receive any check. Do not plant them very close, for then their beauty is not seen. I have selected only those which grow compact and which continue long in bloom. As they are to adorn designs their size and habit must be studied. Many of these annuals may be pegged down with advantage, the Phlox Drummondii for instance. When treated this way the beauty of it is much enhanced.

The contrast of colours I shall leave to individual tastes, but I may just repeat that the rules of contrasts and harmonies of colour are derived from Nature. Yellow, red, and blue are contrasts in all their shades, and the tints formed by the union of any two of these form harmonious colours. In the following list the six first-named are foliage plants:—

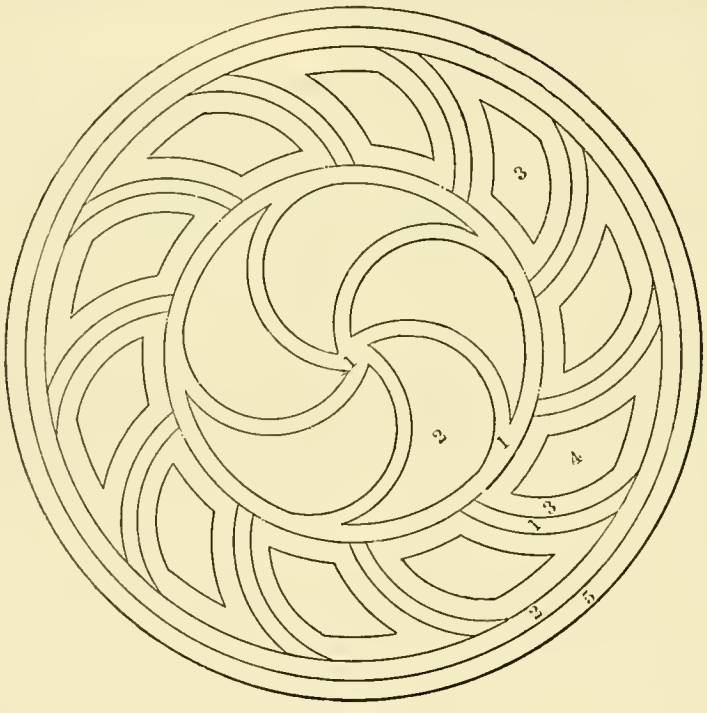

Fig. 113.—BED A.

Amaranthus melancholicus rubar.
Atriplex hortensis rubra. This will require pegging down.
Celosia Huttoni, new, bright crimson and claret colour.
Golden Pyrathrum.
Perilla nankinensis.
Tagetes signata pumila.
Ageratum Imperial Dwarf, blue.
Asperula azurea setosa, blue.
Aloosoa Warscewiczii compacta, scarlet.
Alyssum maritimum, white.
Bartonia aurea, bright yellow
Clarkia alba, white, red, rose, violet.
Convolvulus minor, white, blue, dark violet.
Clintonia pulchella, blue and white.
Eschscholtzia croces, orange and white.
Godetia, rose, purple, white.
Lupinus nanus albus, white.
Marigold, French Miniature, brown and yellow.
Malope grandiflora, crimson, purple, white.
Mesembryanthemum, rose, purple, white.
Nasturtium Tom Thumb, rose, crimson, scarlet, yellow.
Nemesia compacta, blue and white.
Nemophila, purple, white, blue.
Petunia, many colours.
Phlox Drummondii, purple, rose, pink, white, crimson.
Saponaria calabrica, rose, white, pink.
Senecio, crimson, red, purple, white.
Viscaria, scarlet, rose, white, crimson.

BED A.

1. Cineraria maritima compacta. A new and almost pure white, a great improvement on Cineraria maritima. It is nearly hardy, and strikes freely from cuttings at all times.

2. Golden Pyrethrum. It is uniform, neat, and compact, forming an equal surface. Sow the seed in March in a greenhouse or frame, or outdoors on a warm border. Small plants at bedding-out time are better than large plants, as they are not so apt to run to seed as are older plants or cuttings.

3. Lobelia Blue King. A light sky blue and free-flowering variety, constant in bloom until the frosts cut it down. It makes a charming groundwork for bright colours.

4. Alternanthera amœna spectabilis. Of all the new and ornamental-foliage plants for the flower-garden decoration throughout the summer months the Alternantheras are the most useful. It is essential in forming brilliant combinations; its colour, brilliant magenta red, being invaluable for contrasts in designs. It is a marked improvement on A. amœna, brighter in colour and stronger in growth. Propagate in heat in March and April, grow on in heat, shade from the sun, and the greener they are the faster the plants will grow. Let them have air and sun a week before they are planted out, and they

will soon colour and make a fine feature in panel and geometrical groundwork.

5. Echeveria glauca metallica. A very distinct and valuable addition to this class of summer bedding plants. A deep glaucous green with a bronze hue, large showy leaves, free and dwarf grower. Propagated by offsets and seed.

BED B.

1. Golden Pyrethrum.

2. Lobelia Stonei, new, and producing a profusion of dark blue flowers. A very compact and upright-growing variety; a marked improvement on the speciosa section; it is the desideratum in the Lobelia group. Cuttings in March or April make nice plants by the 1st of June. Grow them on in heat the fore part of the time.

3. Alternanthera paronychyoides major, new, orange and carmine. It makes a beautiful contrast with the blue Lobelia. It has proved one of the distinct and attractive bedding plants of the past season, so it can be recommended on its merits; in a word, it is an exceedingly pleasing acquisition.

4. Alternanthera magnifica. Orange and red. We use this sort very extensively in the London parks, and with great success. It is most highly ornamental, and rather a vigorous grower, but still close and compact. This beautiful variety will be found as effective in tone of colour for elegant contrasts as others in the same group.

5. Echeveria secunda glauca. The utility of this plant for bedding purposes is well known—for margins of beds it is extremely effective; indeed, it is one of the most attractive and useful bedding plants in Hyde Park, where there is an immense quantity of it used.

6. Alternanthera amœna. Colour magenta.

7. Stellaria graminea aurea, a new and elegant little golden plant. It is exceedingly useful and ornamental. It is a valuable addition, and is very effective as a margin, and the closer it is kept clipped the brighter it becomes in colour. It is worthy of a place in the most select designs. It is hardy, and may be propagated by pulling it into small pieces. It contrasts beautifully with the grass, and shows the bed to perfection.—N. Cole.

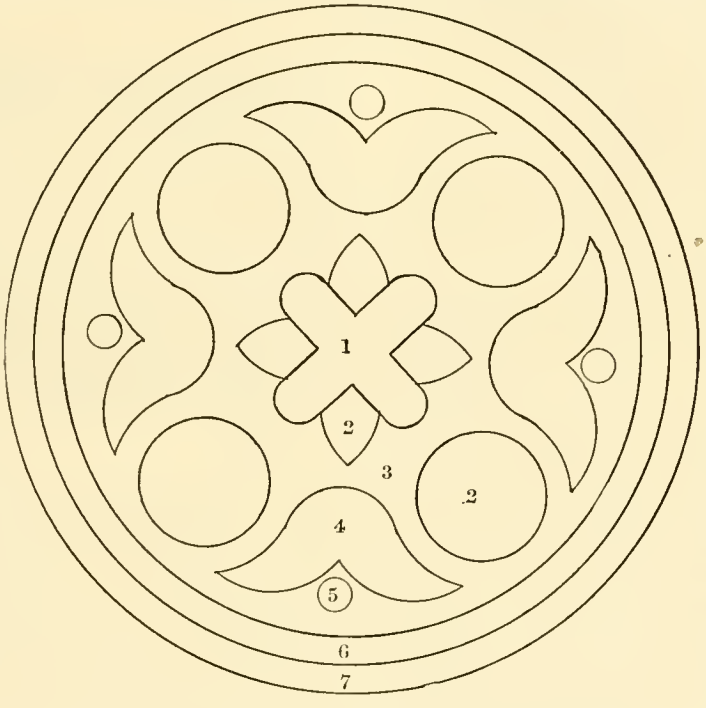

Fig. 114.—Bed B.

IN THE WEST COUNTRIE.—No. 1.

THE EXETER ROSE SHOW.

The first gage in the great tournament of 1875 was thrown down as it is fitting in the fair capital of the west, and right well (notwithstanding the really awful weather of the past week, when storm, and hurricane, and rain seemed to be striving for the mastery), was the contest upheld; and yet it was not a little strange that the only exhibits in the large classes amongst nurserymen came from Slough and Cheshunt, while Exeter, Torquay, and Hereford were unrepresented; and although the first prize amongst amateurs fell to Mr. Baker of Heavitree, yet the second prize was carried off by Mr. Gould of Reading, in the large class. It was indeed a marvel that such flowers could be staged after such weather as we have had. Doubtful indeed must have been the thoughts of the indefatigable Secretary of the Exeter Society when, the day before, rain and sunshine alternated throughout the day, and happy must he have felt as the day broke with a fine clear sky, and a really perfect day for a show day succeeded the stormy and chilly one of Thursday; and as he looked through the tents and saw the trays of bloom that were all ready for the fray, Mr. Gray must have felt that the growers had well supported him in his time of need.

The contest in the nurserymen's class lay between Messrs. Paul & Son and Mr. Charles Turner—close enough in the class for seventy-two, and so close in that for forty-eight trebles that the Judges were compelled, after much hesitation, to place them equal Messrs. Paul & Son's were a more even lot, and Mr. C. Turner's bore the palm in size. In the collection of the former the following were particularly good:—Madame Charles Wood, Dupuy-Jamin, Reynolds Hole, Fisher Holmes, Robert Marnock, Marquise de Castellane, Wilson Saunders, Cheshunt Hybrid, Marguerite de St. Amand, Louis Van Houtte, Prince de Portia, Madame Lacharme, Etienne Levet, Camille Bernardin, M. Hippolyte Jamain, Général Jacqueminot, The Shah, La France, and Thomas Mills. In Mr. Turner's the following were especially fine:—Nardy Frères, La France, Xavier Olibo, Abel Grand, Ferdinand de Lesseps, Devienne Lamy, Monsieur Boncenne, Centifolia Rosea, Senateur Vaisse, Charles Lefebvre, Marie Van Houtte, Mrs. Baker, Madame Lacharme, and Mona. Boncenne. And here let me say that it is my decided conviction that I ought to advise (save that I am a man of peace), my good old friend Lacharme to indict that reverend libeller the Rev. J. B. M. Camm and other offenders for a libel on his wife. No names were too bad for her—"coarse as a navvy," and "dirty as a scullion" (pretty well that, I think, for a mild man), had I not then a grim satisfaction in taking this reverend calumniator by the ear (metaphorically), and bringing him over to these blooms and making him confess that as a white Rose she is utterly unrivalled. It is said she requires fair weather (well, we have not exactly had fair weather lately), and so do other high-prized Roses—Mona. Noman, Mdlle. Eugénie Verdier, and others; yet no one abuses them, no! Madame Lacharme is the best white pot Rose we have, and I would fain believe we have none to equal her for outdoor work. In the class for forty-eight trebles Mr. Turner and Messrs. Paul & Son were, after a very close contest, placed equal first. In Mr. Turner's were good examples of Baronne Rothschild, Devoniensis, Alfred Colomb, Maréchal Niel, Madame Lacharme, without a tigne of blush; Louis Van Houtte, and Etienne Levet. In Mr. Paul's were Marquise de Mortemart, Cheshunt Hybrid, François Michelon, Madame Lacharme, The Shah, Beauty of Waltham, Eugénie Verdier, Reynolds Hole (very good), Senateur Vaisse and Marquise de Castellane.

Amongst amateurs Mr. R. G. N. Baker of Heavitree was pre-eminently first, and some of his blooms could not be surpassed for colour and form. I have never seen, I think, Duke of Edinburgh so thoroughly and intensely scarlet without an atom of shading, while such a box of Charles Lefebvre as he set up I have rarely if ever seen. Among his forty-eights the following were very fine—Madame Caillat, Alfred Colomb, Duke of Edinburgh, Ferdinand de Lesseps, Catherine Mermet, President Thiers, Senateur Vaisse, M. Noman (very fine), Fisher Holmes, Souvenir d'Elise Varden, and Marquise de Mortemart. In his twenty-fours I noticed Madame C. Wood, Baronne Rothschild, Madame Victor Verdier, Duke of Wellington, Marie Van Houtte, Horace Vernet, Marie Baumann, and Souvenir d'un Ami. In the class for eighteen trebles Mr. Baker was again first, amongst others with grand blooms of Mad. Eugénie Verdier, Xavier Olibo, Baronne Rothschild, Marquise de Mortemart, Ferdinand de Lesseps, Duke of Edinburgh, and Lord Macaulay. In the class for twelve Roses of any one sort the first prize was awarded to Mr. Baker for Charles Lefebvre, and the second to Comtesse de Paris, bright crimson rose, unknown to me, but as shown

here was exceedingly bright and good. In the class for new Roses Messrs. Paul & Son were first with Wilson Saunders, very fine; Capitaine Christy, good; Madame Nachury; Ingenieur Madele; François Courtin; Robert Marnock, good; Annie Laxton; Sultan of Zanzibar, good, and as dark as Mons. l'Africane can desire; and Mdlle. Marie Finger, very like Mdlle. Eugénie Verdier. Mr. Turner was second with Jules Favre, Miss Hassard, Oxonian, Warrior, Peach Blossom, Rev. J. B. M. Camm (good), Wm. Gates, Beauty of Thame (dark and fine), J. S. Mill, General Chanzy, and Beauty of Slough, a promising full rose. Want of space compels me to pass over the other classes.

A tent was set apart for Table Decorations, which, as they always are at Exeter, were very good. The prizes were awarded by a lady who has been herself a most successful exhibitor, and yet some of the decisions were much questioned. The first prize for three stands, which was awarded to Miss E. Wish of Broad Clist, was far too large in the base—there would have been room for nothing else on the table; while we thought that had Messrs. Veitch taken away the Anthurium Scherzerianum from the top they would have been far the best. There was one single vase which obtained the second prize, which was charming; it contained some sprays of Spiræa, Rhodanthe, Clerodendron Balfourianum, and some Grasses. The stands of wild flowers were also very good.

The Show was a very successful one, and all who had to do with it may be congratulated on a result which at one time seemed doubtful. For myself I can only tender my hearty thanks to all those brethren in the craft who gave me, as they always do, so kindly a welcome, and make my Exeter trip one of the pleasantest I have in the year.—D., *Deal.*

NEW DISEASE AFFECTING AMERICAN POTATOES.

I, WITH yourselves, regret this disease, though I feel glad that the warning came from the right men in the right place. Early this spring it was fully expected that my position here would have been disturbed, but I took the precaution to rent some garden ground at Old Woodstock, in which to grow and make sure of my new seedling Potatoes. An extra plot also I took to my aid, on purpose to grow the modern Americans, a piece of ground noted for the good products of our English esculents. But about three weeks ago I observed something was going wrong amongst the Yankees. I mentioned this by writing to my chief Potato-cultivating friend who grows them, asking how his were "coming up." The answer was, "fairly well." Now my disagreeable information is that three parts of my American sorts are "gone off," and that just after their appearance above ground, something after the fashion which used to occur in our younger days called "bobbin jones," resulting from heap-storing, frequent spurting and cutting the seed—viz., young shoots struggling just above the soil, then to curl up within, and be seen no more. The present complaint could not be from the cause of "bobbin jones," for I had petted the sets and kept them in single layers in wooden trays, and not a shoot on them was suffered to take any bruise, excepting that I felt compelled to cut what Mr. Radclyffe has christened the "whoppers!" But I dusted lime over their incised surfaces before planting. However, the curling kept on; my men said it must be the continued moulding slightly over head and ears, to guard against night frosts the Americans did not like; but I felt confident it was not that, so about ten days ago I stayed all "fretting" and ordered every shrivelled-foliaged set to be forked up, and at once sowed some Beck's Improved Snowball and Orange Jelly Turnip seed on their sites on the ridges. My surmisings by this procedure were at once clinched, and I await for a further knowledge of the cause from Mr. Berkeley.

The cut sets as dug up were as sound as they well could be, after being some weeks buried within the soil, but the uncut tubers were as sound apparently as when they were planted, so much so that I presented them to my landlord's pigs. But the young shoots? They were withering away, having a brown sere appearance just up to 2 inches from whence they issued from the sets, and tubers. That was the cause of the mischief, But what caused that? At any rate it will prevent me achieving a crop of "whoppers."

The sorts I have this season are Extra Early Vermont, Snowflake, Late Rose, Brownell's Vermont Beauty, Willard's Seedling, and Thorburn's Paragon. Of the crops of my neighbours the freest from the contagion are Bresee's Prolific and Early Rose, two sorts, luckily for them, most in cultivation hereabouts, and I hope all those that mean to die off have done so, though my whole planting of Brownell's Vermont Beauty are looking very uncanny after having arrived at a foot or more in height; even some of the stools of Thorburn's Paragon are dying away, imported seed of this season (?) Bresee's Prolific and Early Rose, being some of the first importation, are *perhaps* acclimatised.

I will write to you again when I have experienced the worst that is likely to happen this season. News has just arrived to me from Banbury that the contagion is there, so I fear we shall hear of its becoming general. I hope and trust our "cousins" will not introduce here their Colorado beetle.

Our English Potatoes about here, including all my new seedlings, are looking unexceptionably well and robust. One of my friends says he is digging Mona's Pride "as big as his fist," and that is none of the smallest. I have not seen them—that is, the big tubers, but his growing crop above ground certainly gives augury for a fine produce, though should the present tempests and the electrical state of the atmosphere continue I shall have to write you ere long to complain about them becoming diseased also, by which you will observe that I still stick to my creed. Well, nothing would give me greater pleasure than to shake "our Editors" by the hand, and to chaperon them over my crops, and a few other things besides Potatoes, which they would feel an interest in should they shape their course this way.—ROBT. FENN.

THIS seems to be prevalent in nearly all parts of the country. I left a bundle of haulm at the office (171, Fleet Street) on the first week in June: some of it was from the gardens at Loxford, and the other portion was brought to me by an amateur. It has appeared here only on the American sorts; a small patch of Extra Early Vermont in the middle of a field has it bad—nearly half destroyed. On the warm sheltered borders it is the same. Myatt's Prolific on one side and Veitch's Royal Ashleaf on the other are sound, while the American is badly diseased. The disease may not be infectious; if it is, it will be a great pity that any of the American varieties were introduced. The experience gained at Loxford is all against them. A high price was paid for Early Rose, and after growing it for two or three seasons it was rejected as a miserable failure. We have now tried what was thought the next best red early sort—the one named above—and it cannot this year be distinguished from Early Rose either in haulm or tuber, and the disease to boot; it will probably go to the pigs like all the rest of them. No more Americans if I can have my way.—J. DOUGLAS.

[Since the announcement made last week we have examined more closely the Potatoes growing, or rather dying, in the gardens of the Royal Horticultural Society at Chiswick. There can be no question but that the disease now established there is exceedingly virulent and destructive, and, like all other new diseases, mysterious. This new disease is not now seen for the first time at Chiswick, and we had no difficulty in recognising its identity with occasional and limited examples of an affection pertaining to the Early Rose which we have seen in different parts of the country during the past two or three years.

We think many cultivators must, in past years, have observed in their vigorous plantations of the variety named a root here and there wither and die. The foliage becomes spotted, the stem discoloured, and in a few days not a vestige of green is left; in fact, to use a familiar term, which is exactly appropriate and expressive, the plants have "damped off." When this occurs, which is commonly the case when the young tubers are just forming, the crop is necessarily ruined, not because the tubers necessarily decay, but because their growth is stopped before they have attained a size fitting them for any useful purpose. Now that (of which isolated instances will have occurred and be in the recollection of those who have cultivated this variety from home-raised seed tubers), is the identical disease which has spread so extensively as practically to destroy the crop at Chiswick.

Mr. Barron might, as a matter of curiosity, have directed attention to the disease existing to a limited extent in previous years, but, as a practical man, he was cautious in raising a feeling of alarm, and wisely waited for evidence. This evidence is now forthcoming, and proves beyond any manner of doubt that the American varieties of Potatoes grown from home-raised or English seed are specially liable to a visitation which may, as instances at Chiswick prove, render the crop worthless. The information we gave was not a moment too soon, for the disease is an established fact, not as a pathological

discovery merely, but as a destructive agent jeopardising the crop of a valuable esculent.

At Chiswick we note three distinct circumstances—viz., First, that the disease is extensive; second, that English varieties are perfectly free; and third, that it is nowhere present in the crops of American varieties from imported seed.

The disease is not in one part of the garden alone, but in every part where American varieties are grown. In one quarter we find rows of Regents, every plant of which is in perfect health, and the next row of Early Rose is practically ruined. Some roots are fresh enough, but for twenty roots together decay of the haulm is complete. On another border which is devoted to the trial of several kinds, we find amidst Mr. Fenn's seedlings (which are uniformly healthy and in a high degree promising), six rows of American Snowflake with ten sets in each row. Out of these sixty sets there are just six healthy plants, the rest not being slightly affected, but the haulm absolutely decayed and the produce worthless. Again, we find rows of American Breadfruit, imported seed supplied by Messrs. Carter & Co., perfectly healthy, and Snowflake by their side from English seed extensively diseased. The disease is thus limited to American varieties from English seed, the garden affording no instance of an English variety being affected, nor yet an American variety from imported seed.

Having noticed the incidence and peculiarities of the disease we glance at its characteristics. So far as we could see, the main—visible—seat of the malady is the stem of the plant just at or very slightly within the surface of the soil. It is best explained by the perfect analogy afforded by a decayed post; above ground it is sound, and below sound, but between these points it is decayed.

Out of dozens of stems we pulled up not one of them but was most affected at the point named. Some were absolutely rotten, and affording a feeding ground for grubs and fungi; while others only slightly affected were merely discoloured and partly shrivelled, precisely and exactly as are plants which are "damping" or "fogging off." The old sets of some were perfectly sound and healthy, and were even pushing out fresh growth; and some of the stems which above ground were rotten, below it were pushing fresh white rootlets. Is the fungus which takes possession of the plants the cause or the effect of the disease? That is an important point to determine; but taking a practical rather than a scientific view of the case, we cannot suppose it to be the cause. That, however, is the subject of special investigation.

The disease is distinct from the old murrain in appearance, and also in being affected by weather influences. The old disease spreads most rapidly with rain; the new increased the most quickly under the late dry sunny weather. Since the rains the progress of the malady has been slower, and the plants are generally more healthy and show fewer fresh outbreaks. It would appear that the real seat of the disease is in the seed tuber, and that when once acquired it is hereditary. Certain it is that in instances more or less frequent it has exhibited itself during the past few years, and, unfortunately, not much less certainly is it increasing in virulency. At Chiswick it is unquestionably severe, and the warning we have given is no hurried note of alarm, but a timely notice of an established outbreak. All the American varieties from English seed are affected except Alpha.

Although at Chiswick none of the crop growing from imported seed is attacked, Mr. Fenn's experience proves that such seed is not invulnerable to the inroads of the disease.—Eds.]

ROYAL HORTICULTURAL SOCIETY.

On the 16th there was a meeting of some of the Fellows at the Charing Cross Hotel, "to consider the present position and prospects of the Society." Mr. A. F. Godson, the Chairman, said the object was to prepare a practical scheme to extricate the Society from its difficulties. Mr. Shirley Hibberd said the Fellows could not sell their land, and they had no available assets. The arrangement must provide for existing covenants, to perform all duties prescribed by the charter, to make the best of the lease, the best of the Society's relations with the Commissioners of the Exhibition of 1862, and the very best of the local Fellows. To reconstruct the Society on a sound basis the London garden must be kept in the most perfect condition possible, and improvements should be made in the gardens by which the expenditure would amount to £17,000 per year. The subscriptions for the Fellows residing within a mile of the gardens at Kensington should be £10 10*s.* annually. The raising of the subscriptions would tend to enhance the value of the attractions by restricting the enjoyment of them to a select company. He believed this would raise the Society's income from subscriptions of Fellows alone to £20,000, which would leave something for the redemption of the debenture debt. Assuming that only 1000 Fellows joined at £10 10*s.* it would realise 10,000 guineas. The exhibitions, life compositions, admissions to the gardens, and miscellaneous receipts would bring the income up to £20,000, and, as the working expenses would be £17,000, there would be a balance of £3000 to pay off the debt. He moved, "That in any scheme which may be promoted with a view to the restoration of the Royal Horticultural Society to its original high position, the annual subscription of Fellows within one mile of the gardens at South Kensington should be fixed at a *minimum* rate of ten guineas, and that the Fellows' tickets should be used only by resident members of the families of Fellows." Mr. R. Dean, Dr. Denny, Mr. P. Barr, Mr. D. Wooster, and others addressed the meeting, and a general opinion was expressed that the failure of the Society was mainly due to bad management, caused by dissensions in the Council. The resolution was then carried, and it was decided that it be forwarded to the Council of the Society.

GROS GUILLAUME VINE.

Mr. Abbey is perfectly justified, according to his own experience with this fine Grape, in differing from me in common with the author of the "Fruit Manual" and Mr. Luckhurst, as to its being a shy bearer under the orthodox system of short-spur-pruning. With Mr. Abbey it has fruited freely under that treatment, and perhaps it may continue to do so, and—perhaps not. For the first few years of a Vine's life the orthodox form of close pruning is permissible with any variety, for so long as there is a yearly extension of cane which has not to be cut away, the system of cutting-in the side growths can hardly be called "close pruning." It is when there can be no further extension, but when every shoot, including the terminal one, is cut to within half an inch of the previous year's wood, that Gros Guillaume is so often shy in producing fruit, while other varieties yield Grapes in the greatest perfection.

Notwithstanding Mr. Abbey's experience to the contrary, I am of opinion that the shyness of the Grape in question under the common mode of pruning is to be attributed its absence from nine-tenths of the vineries in the country. If it is not generally shy why this significant absence? It cannot be that its quality is either inferior or its appearance anything approaching to poor, for to the eye it is fine and to the palate agreeable. For a few years it is common for this Grape to bear well, but after the Vine has filled its allotted space and close pruning in its integrity is carried out, then it is that failure has been so common as practically to banish it from many establishments. Had it been really a free bearer under the ordinary system of pruning its other good qualities must have ensured its increase; it would, like the Black Hamburgh, Alicante, and Lady Downe's Seedling, have been planted as a staple variety, whereas the rule is to limit its culture to a Vine or two in a place, just to "keep the sort."

The author of the "Fruit Manual" says the Vine is "a bad bearer except on poor soils," which amounts to this—that in ordinary soils it is of gross habit, and hence must not be mutilated so violently as those of moderate growth. Mr. Luckhurst has found that to be true. So have I. I have found the Vine to bear freely for half a dozen years, and then to cease showing fruit. I have seen it year after year under the hard pruning practically barren, and subsequently on affording it more room and an extension of cane again become satisfactorily fruitful.

I had last year opportunities, in at the least twenty instances, of seeing this Grape grown, but only in one place was it really satisfactory and relied on as the staple late Grape; and this case afforded a striking proof of the soundness of Mr. Luckhurst's views and my confirmation of them. There were twenty Vines in the same house and border, and of the same age. Some of these Vines and some parts of the others had been pruned closely in to the old wood, the rest and other portions being furnished with canes laid in thinly from the previous year's growth. The advantage of the long pruning was overwhelming, for there alone were the grand Grapes. I have experienced precisely the same results, hence it was that I was

glad to see Mr. Luckhurst treat of this fine Grape in, as I believe, so sound a manner.

I think I am right in regarding Mr. Abbey's success as an exceptional circumstance, and not to be laid down as a rule, that Gros Guillaume is as free as other varieties of Grapes under the ordinary system of culture. A local example or two of success does not in my opinion prove this Grape to be a prolific and generally free bearer any more than Mr. Hunter's honourable triumph proves that a general characteristic of the Black Hamburgh is the production of Brobdignagian bunches. I am glad the subject has cropped-up, especially if it results in a good Grape being better grown, as I think it might, by a relaxation of the orthodox rule of hard close pruning.—A Northern Gardener.

FORGET-ME-NOTS FOR SPRING GARDENING.

Very common is it for cultivators and admiring on-lookers to descant on the merits of these charming spring flowers when the beds and borders are made gay with them in their blooming period. When it is seen how effective they are many owners of gardens who have them not decide upon procuring them. That is one period when we hear much of the merits of Forget-me-nots, and the next period is in the autumn when summer flowers are waning, and when something must be found to take their place. But between these two periods these beautiful hardy spring flowers are seldom noticed; probably because summer flowers then absorb attention. Yet the period when Forget-me-nots are not to be seen—just after they have done their work and the plants are removed from the beds—is the most important of all times at which to direct attention to the usefulness of this attractive family of plants.

To enjoy them in fullest beauty in the early months of spring we must commence our preparations at midsummer. Because this is a busy period attention to these plants is too often postponed—preparations are commenced too late, and the plants are small in the autumn, and the bloom in the beds in the spring both late and unsatisfying.

If the seed is sown late the bloom is both late and weakly, and this is the position of, perhaps, nine-tenths of those who attempt to grow Forget-me-nots. Even in gardens where spring flowers are really desired and are specially welcomed, the practice is common to dib-in small plants from seed which had been sown late, and which is not doing justice to the plants themselves, and is also calculated to bring spring gardening into disrepute.

The few who grow these plants in the finest perfection in the spring are at the present time sowing the seed or dividing the plants. It is only by sowing the seed now that good plants can be had in the autumn of a size sufficient to produce an early and a fine display in the spring. Instead of the small seedlings which are set with the dibber we must have dense stocky plants 6 inches in diameter, and which will take up with a ball that can hardly be crammed into a 5-inch pot. Those are the plants to satisfy either for indoor or outdoor decoration. It is impossible to have them by the too common mode of seed-sowing in August. Such plants can be had by sowing the seed at the present time.

Take, for instance, the Myosotis dissitiflora, and what have we more attractive for indoor decoration in February and March, and for garden decoration in April and May, than well-grown plants of this fine Forget-me-not? Hardly anything can be more charming; but late-sown and weakly-grown plants are always disappointing. Whether M. arvensis, M. sylvatica with their white varieties are used, or the best of all the blues, M. dissitiflora, the seed must be sown at the present time. A moist shady border is the best place where to sow the seed and also to prick out the plants to grow on until they are required for the beds.

A portion of these plants if potted and brought on in a light greenhouse will make a beautiful display in the early days of spring. Plants which have bloomed may also be cut down and divided. If in a moist place they grow rapidly, and should be again divided towards the autumn, for very large plants do not flower well, as the central crowns are apt to be weak. But whether by root-division or by seed, it is an easy matter for all who choose to do so to have a supply of these charming spring-flowering plants in the best condition, providing the work of preparation is commenced at once.

Seed-sowing in June, a cool place for growth in summer, with room for each plant to develops itself and an abundance of water at all times, and especially as the flowering period approaches, are the principal requirements to have Forget-me-nots in perfection.—J., *Clapham.*

LATE-KEEPING GRAPES.

I have now growing in one house three varieties of late Grapes, two Vines of Black Alicante, four of Lady Downe's Seedling, and two of Mrs. Pince's Muscat. At this time (June 16th), Lady Downe's Seedling is scalding very much and has small bunches. The Black Alicante has very fine bunches, and to all appearance are likely to be a very fine crop, but they have not a good flavour when ripe, being washy and soft. Mrs. Pince has the finest bunches and has set the berries as freely as a Black Hamburgh. The berries are very fine. I find that to bring it to a good colour it is necessary to use some heat in the spring and to have it ripe before the autumn. As for flavour, neither Lady Downe's Seedling nor the Black Alicante are nearly so good.

I should recommend anyone making a new border to use plenty of bones, charcoal, and some rich turf mixed with lime rubbish and broken bricks. A border 18 feet wide, I should give 9 feet furthest from the roots plenty of good spit manure, let it lie a twelvemonth, and then turn it over and give the border a good dressing. The roots the second year will find the benefit of it. This I have done, and find it to produce fine healthy canes.

I find the Grapes of Mrs. Pince keep the best of the three. —T. L.

THE ROYAL HORTICULTURAL SOCIETY.

Permit me through the columns of your Journal to point out to those of your readers who are Fellows of the Royal Horticultural Society, the baneful effect of the Parthian shot of Lord Bury at the last adjourned general meeting of the Society. If Lord Bury's reiterated recommendation to divide the Society into South Kensingtonians and horticulturists be carried out, then this Royal Society will soon dwindle down into utter insignificance. One reason why the horticulturists consented to occupy the South Kensington ground was because Chiswick had been found too far from town, and now the advice is to go back to a place that has been reduced one-half its size, and that half the most attractive one. Another and a special reason for coming to the present site was to afford an opportunity to a much larger number of people to take an interest in horticulture as a science, instead of being mere lovers of flowers. As no learned society can be supported by its scientific members alone, it becomes necessary to attract as well as instruct the unscientific public, and for our science no spot could be better suited than South Kensington; but if these beautiful gardens are to become a mere square and nursery for the surrounding housee, then as one of the public I say the Royal Commissioners would not be justified in retaining so valuable a building site for such a purpose, and I should consider it my duty to instruct the members for the county to inquire why such property should not be applied to scientific purposes, and so benefit the whole of the people instead of a few.

Had we a good and an organising brain at the head, this science of horticulture, which is most useful to mankind, would very soon find itself in a most flourishing position; for not only would it be well supported by the London world, but Fellows out of every town and county would come forward to help our well-loved science, and £20,000 a-year would be more easily raised than the present income of £6000.—A Country Fellow and an Amateur Horticulturist.

POROUS GARDEN POTS.

I venture to detail a few items of my experience, having used porous pots for a considerable time for greenhouse plants from the thumb-pot up to the 12-inch. They are so porous that before potting I put them into water to saturate them if they have not been used before or have been stored some time. After being washed clean I find I can grow any greenhouse plant in them tolerably well. Fuchsia and Geranium leaves large and healthy, trusses good. Balsams and Tomatoes most splendid in 9-inch pots. Indian Corn from 10 to 12 feet high in 9-inch pots, with beautiful corn cobs. Hyacinths, Tulips, Ixias, and Liliums, Rhododendrous, Azaleas, &c.—in fact, anything I put into them seems to thrive.

My idea of a porous pot is that when a plant in it is watered the pot absorbs much of the water and gives it out again,

when the soil begins to become dry. I also find the fibres adhering to the inside of a porous pot more than to that of a non-porous pot; also a plant potbound in one of them will be better in health than in a non-porous pot, for the fibres will suck the moisture of the atmosphere through the pores of a porous pot condensed on the outside. I also find cuttings strike more freely in them than in a non-porous pot; they also hold out longer when dry, and a plant is not so soon injured in them as in non-porous pots. Further, I never find the soil become sour in them if overwatered by an inexperienced hand.

I shall be glad if anyone using porous or non-porous pots would state their experience.—J. McAfee, *Gardener, Ireland.*

CYTISUS ADAMI.

It seems strange that in the numbers of June 12th of the *Gardener's Chronicle* and of *Sieboldia* (a Dutch horticultural paper, edited by Mr. H. Witte, Curator of the Botanic Gardens at Leyden), notes are inserted about the same subject—Cytisus Adami. In both papers it is mentioned that on Cytisus Adami both yellow and violet spikes can be seen, and, which is more curious still, that both violet and yellow flowers may be observed on the same spike. Some of your readers may be interested to hear that the latter fact has recently been seen in Mr. R. J. Blaann's garden at Zuidbroek, Netherlands.

Flower spikes of Cytisus Adami have been observed producing both yellow and violet flowers. Mr. Blaann sent one of those spikes to Mr. Witte, who says the following about it in *Sieboldia*:—"The spike which lays now before us is not one of the largest, and already shows by its development to keep a medium between the spikes of Cytisus Laburnum and C. purpureus. It bears fifteen flowers. Examining them from the base of the spike, they are arranged in the following order:—

1 yellow flower	1 violet flower	1 yellow flower
2 violet ,,	2 yellow ,,	1 violet ,,
1 yellow ,,	1 violet ,,	5 yellow ,,

Consequently we find five violet and ten yellow flowers. This fact is so striking that one can scarcely believe it. We do not now again mention the origin of this tree, on which so much has been written. A clear explanation of this fact is until now always a wish which very likely will not be so soon accomplished. For the present we content ourselves with this note, thanking Mr. Blaann very much for his kindness in sending the spike."—A. M. C. Jongkindt Coninck, *Tottenham Nurseries, Dedemsvaart, near Zwolle, Netherlands.*

NEW BOOKS.

The Potato Disease, &c. By Eccles Haigh. G. Philip & Son, Fleet Street, London.

We fail to discern anything novel in this pamphlet, and our readers may judge for themselves when we quote the following as embodying Mr. Haigh's opinion as to preventing the disease:—

"Regenerate through the seed two or three times, and abstain, as nearly as practicable, not only from nitrogenous artificial manures, such as guano, sulphate of ammonia, rape-cake, and nitrate of soda, but also from strong farmyard manure, such as stable manure and that produced by cattle fattened on such food as oil-cake; that furnished from dairy establishments and cow byres approaches to the type of what I would recommend."

Compendious Statement of the Nature and Cost of Certain Sewage Processes. By Major-General Scott, C.B. Scott's Sewage Company, 26, Great George Street, Westminster.

So strongly do we feel convinced from long experience of the vast fertilising power of house sewage that we have published more than one work on the subject, and recommend strongly General Scott's pamphlet to our readers.

EARLY WRITERS ON ENGLISH GARDENING.

No. 5.

JOHN PARKINSON.

Usually, but very undeservedly, our early herbalists are ridiculed, and their researches called "old women's lore." Quite the reverse is my estimate of them and their labours; and all gardeners ought to coincide with me, for the herbalists of the sixteenth and seventeenth centuries were the men who first largely introduced plants worthy of cultivation in our gardens. It is true that they travelled far, and examined them sedulously to obtain from them medicinal aid. In that also they were marvellously successful; but they learned to admire the plants and to cultivate them for their beauty, and they imparted them to others who coveted them only for their beauty.

Prominent among these herbalist-gardeners was John Parkinson. He was born in 1567, for the inscription on his portrait, published in 1629, states that he was then in his sixty-second year—"LXII ætatis annum agentis."

The place of his nativity is not known, but Nottinghamshire was probably the county, for thither towards the close of life it has been stated he travelled to recruit and renovate his strength for his professional duties as an apothecary. There is no room for doubting that Parkinson resided in the parish of St. Martin-in-the-Fields. In his "Theatrum Botanicum" he very frequently speaks of plants that were growing in his "garden here in London," and that it was in Long Acre. Among the State Papers of the time of Charles II. there is a petition dated in September, 1660, from John Chase, His Majesty's apothecary, for a lease, on rental of 20*s.*, of a small parcel of land next the Tennis Court in St. James's Fields, granted by the late King to John Parkinson, his botanist, as a garden for plants, toward the enclosing of which and erecting a house there the petitioner's father advanced £100, on condition of being joined with Parkinson in the grant, but was prevented by the civil war troubles. Now Long Acre and St. James's Fields were both in the parish of St. Martin's. The latter were westward of its church, and were not made a part of the parish now known as St. James's Piccadilly until 1684. Long Acre was not so called previously to 1612, when building had reduced it to a long narrow slip. It had been a much larger vacant space, earlier known as Seven Acres and The Elms. In his "Paradisus" he tells that he had spent nearly forty years in "travell," or as we now spell it "travail," to acquire a knowledge of plants, and, not satisfied with his own researches, he contributed to the expenses of one botanist to enable him to search some parts of Europe for new plants. Parkinson was reasonably displeased with him. The offender was Guillaume Boel, who, says Parkinson, "going into Spaine almost wholly on my charge brought me little else for my money than seeds of Chiceling Peas." Yet he gave seeds to others, so that "I beate the bushe and another catcheth and eateth the bird."

The vicinity, the northern bank of the river, seems to have been long preferred for garden grounds. Even in Domesday Book a vineyard belonging to the King is mentioned as situated in Holborn, and in the period we are now considering we have, in a line along the same elevation Johnson's physic garden on Snow Hill, Gerarde's in Holborn, and Parkinson's in Long Acre. Those gardens were enriched by contributions from our merchants and gentry, several of whom are immortalised in the pages of those three herbalists as lovers and collectors of plants. The following extracts record some of those who thus benefited Parkinson:—

"Mr. Nicholas Lete, a worthy merchant and a lover of all faire flowers."

"Mr. John de Franqueville imparted to me many good things."

"Mr. John Gordier (Goodyer), a great lover and curious searcher of plants, who hath found in our countrey many plants not imagined to grow in our land. I wish there were many more of his minde, that not hindering their affaires at spare times would be industrious to search out and know what the ground bringeth forth where their occasions are to be."

Of the Sea Pea he says that Dr. John Argent brought a whole plant from Lincolnshire, and "gave it to Dr. Lobel in his lifetime to be inserted in his workes, but he, prevented by death, failing to performe it, I have by purchasing his works with my money here supplied."

The desire for new plants and fruits was not confined to men of science and merchants, and one instance is Richard Brown, writing from Paris to Secretary Dorchester in 1631, tells him how he purposes spending the £300 for fruit trees for him, chiefly Pears, Nectarines, and Grapes. Among the Pears are the Summer and Winter Bon Chrétien, Bergamotte, Messeur Jean, Rousselet, and de Beurré. Among the Nectarines the Alberge, Peche cerise, Violette, Blane and Jaune. —(*Col. of State Papers.* Bruce.)

Notwithstanding his pre-eminence as a botanist and his intercourse with the encouragers of science who were his contemporaries, no letters from or to him are known to be in existence, nor any relative MSS. either in the British Museum or Lambeth or Bodleian libraries. I have searched them, but in vain.

The profession of apothecary and herbalist does not seem to have been in those days either honoured or lucrative, as there is no record of correspondence with men of position, nor of a will being proved, or of letters of administration being obtained by the representatives of either Gerarde or Parkinson.

I will now proceed to notice the two publications by which Parkinson is so favourably remembered. Most of my readers will have failed to observe that in the title of the first of those works, *Paradisus in Sole*, is intended a witty translation of Parkinson—Park-in-sun. I will copy fully the title-page because it tells the contents of the work, and the volume has this transcendant merit, it is the first original work on English gardening. The details are full, are the records of the author's practice, and in every department impart sound instruction.

"PARADISI IN SOLE.

"PARADISUS TERRESTRIS.

"A garden of all sorts of pleasant flowers which our English ayre will permitt to be noursed up: with a Kitchen Garden of all manner of herbes, rootes, and fruites for meate or sause used with us, and an Orchard of all sorte of fruit-bearing trees and shrubbes fit for our land, together with the right orderinge, planting, and preserving of them, and their uses and vertues. Collected by John Parkinson, Apothecary of London. 1629."

Fig. 115.—JOHN PARKINSON.

The frontispiece represents the garden of Eden. Adam seems to have gathered the last fruit from a tree, and Eve is attending to some flower. In the foreground is more than one Sunflower, but Tulips, Martagon Lilies, Cyclamens, the Pine Apple, and Carnation are conspicuous. It is dedicated to the Queen, evidently Henrietta Maria, whom he knew "delighted with all the faire flowers of a garden." The address to the reader demonstrates that Parkinson was a well-educated and well-thinking man. "Some through an evill disposition and ignorance have so far traduced me as to say this was rather another man's worke than mine owne, but I leave them to their folly." He adds that he always had "a naturall inclination" to such pursuits, and evidently was referring to the "Herbal" he subsequently published when he says that he has a work "larger, as time may suddenly, by God's permission, bring to light." If the work was successful it would "hasten the fourth part—a Garden of Simples, which will be quiet no longer at home then that it can bring its master newes of faire weather for the journey." That weather came in 1640.

He recommends Box as an edging, as yet "only received into the gardens of those that are curious." He denied the moon's influence over garden operations, for, after many experiments, "I could never see the effect desired." So grafting the Rose on the Broom to obtain yellow flowers, and many other follies, he firmly adds, "I assure you they are all mere idle tales and fancies." "I have of Roses to furnish this garden thirty sorts at the least, every one notably different from the other both for colour, form, and smell." They were—1, White English Rose, single and double; 2, Carnation Rose, pale blush and very double; 3, English Red Rose, "more frequent used in England than in other places;" 4, Damaske Rose, "of most excellent sweet pleasant sent;" 5, Great Double Damaske Province or Holland Rose, "that some call Centifolia incarnata;" 6, Red Province Rose, "called Centifolia rubra;" 7, White Province Rose, "whereof I am not oculatus testis;" 8, Party-coloured Rose, "of some York and Lancaster;" 9, Chrystall Rose, striped as "the Chrystall Gilloflower," dark stripes on pale ground; 10, Dwarf Red or Gilloflower Rose; 11, Franckford Rose, pale red; 12, Hungarian Rose, pale red; 13, Velvet Rose, single and double, "like unto crimson velvet;" 14, Rose without Thornes, single and double, pale red; 15, Cinamon Rose, single and double, pale red, with "small sent of Cinamon;" 16, Single Yellow Rose; 17, Double Yellow Rose, "few abiding whole and fair in our countrey, the cause whereof wee do imagine to bee the much moisture of our countrey;" 18, Muske Rose, single and double, "creame colour;" 19, Double White Damaske Muske Rose; 20, Spanish Muske Rose, white with a blush; 21, Great Apple Rose, deep blush; 22, Single Eglantine or Sweet Briar bush; 23, Double Eglantine; 24, Evergreen Rose, white, "of a fine sent; leaves abide for the most part all the winter."

"Gilloflowers" were then "the pride of our English gardens." Of Tulips he had 160 varieties, and "scarce any lady of worth but was a delighter in them."

In the Kitchen Garden he gives full and correct directions; but many observations, such as that Cabbages were eaten chiefly by "the poorer sort of people," are evidence that animal rather than vegetable diet prevailed. He has the merit of having introduced the Rhubarb plant, it being sent to him "from beyond sea by Mr. D. Matthew Lister." In the Fruit Garden he gives good directions for the culture and propagation of all the species now its tenants, but want of space prevents me making more than this extract, "Nectarines have not been with us many years." Although he dedicated the volume to the Queen he did not accept the Roman Catholic faith, for he condemns most strongly its priests for their false statements about the Passion-flower.

In 1656, six years after Parkinson's death, a second edition of the "Paradisus," "much corrected and enlarged," was published. After the lapse of eleven years his principal and only other work was published entitled, "Theatrum Botanicum: the Theater of Plants, or an Herball of a large extent." The title-page states much more of what the pages contain—"Collected by the many yeares travaile, industry, and experience in this subject, by John Parkinson, Apothecary of London, and the Kings Herbarist. Published by the Kings Majestyes especiall priviledge." 1640. He dedicated "this manlike worke of herbes and plants" to the king, as he formerly did "a feminine of flowers" to the queen. The civil wars, or, as in the preface he terms them, "the disastrous times, but much more wretched and perverse men" had hindered the publication. It "hath changed the note" and certainly increased its value, for instead of "a Physicale Garden of Simples" it was now "a Theater of Plants."

Parkinson wrote unjustly when he expressed himself sneeringly about "Master Johnson" for hastening to edit a new edition of Gerarde's Herbal. The work was needed, and Parkinson tells us that he should have published his "Theatrum Botanicum" at the same period had not the civil wars interfered. Johnson, writing in 1633, speaks more generously, saying, "Mr. John Parkinson, an apothecarie of this city (yet living and labouring for the common good) hath not superficially handled these things."

The contents of the "Theatrum," being entirely botanical, I will not detail, but I cannot resist quoting one sentence. In speaking of one of our native plants he says it grows "on the backeside of Grayes Inne, where Mr. Lambe's Conduit heade standeth." We here see the derivation of the name of that well-known street.

Writing in the April of 1640 Dr. Mayerne mentions that the king had recently made Parkinson "Chief Royal Herbalist," and this is the latest notice of him that I have met with previous to the record of his death. The register of burials in the parish of St. Martin-in-the-Fields contains this entry—"1650, Aug. 6, John Parkinson sepultus." Guided by the inscription on his portrait we thus learn that his death occurred in his eighty-third year.

During the Protectorate I find no notice of him, but among the State Papers of the date of May, 1660, there is an order for a grant to Dr. Robert Morison of the offices of botanical physician and chief herbalist to the king (Charles II.), in the place of Matthias de Lobell and John Parkinson, with the

physical garden in St. James's Fields for medicinal plants; also of overseer, director, and gardener of Hampton Court and the privy gardens at St. James's.

TREE FERNS.

This is a family of plants of undeniable beauty, and which contribute a distinct effect to any suitable structure in which they are cultivated. The New Zealand species of these fine Ferns cannot be too highly prized, as they combine with a decidedly tropical appearance the power to flourish in a cool temperature. This is a great advantage, for while it was thought necessary to provide a high stove temperature to enable tree Ferns to flourish, it was practically to debar many from attempting their culture; but since some of the species are found to be comparatively hardy, they supply a want in occupying space ornamentally in many cool conservatories.

It cannot be denied that in many structures devoted to the display of plants a special want is often felt. Plants on stages are arranged in flat formality, and which at first are imposing by their massiveness, but a desire for a more cool, quiet, and natural form of ornamentation is eventually felt. Smooth banks of flowers, globular Camellias, and stately Azaleas are beautiful, but are infinitely more effective if, springing from among them and towering aloft, are stately Palms and towering tree Ferns. In lofty conservatories there is a blank of unoccupied space between the climbing plants drooping from the roof and the flowering plants arranged on the ground or on stages which detracts from the furnishing of the structure. To supply this deficiency tree Ferns are admirably adapted. To appreciate the satisfying effect which is created by these noble plants, we have only to witness the well-arranged public exhibitions in which tree Ferns are used. These plants judiciously interspersed tone the overpowering sense of brightness of long banks of flowers, and relieve the monotony inseparable from the grouping of flowering plants alone.

Fig. 116.—Alsophila leichardtiana.

The time will come when the conservatory will not be composed of geometrical beds and longitudinal stages wherein and whereon plants are arranged to form a dense close mass having the main object to dazzle, but rather a free plantation of tropical aspect will be sought for, and which will afford a roomy promenade beneath cool canopies of foliage which only Palms and tree Ferns can provide. These stately plants carefully disposed, and brighter examples of decorative plants arranged in natural freedom at their base, will be the occupants, and the mode of associating them that will be recognised as the most suitable mode on which to furnish a conservatory.

The day of mere glare has passed its meridian, and the taste of the times is every day becoming more refined. Tree Ferns and kindred plants tower high above mere fashion, and their merits are being recognised, and they will be more esteemed in the future than they have been in the past. It is also satisfactory to notice, that as the taste is being moulded to appreciate more fully the grace of plants, so in the same proportion are these plants being provided. Trade enterprise in a great commercial country like ours will always expand with public demands, and experience is teaching—indeed has already taught, the best mode and time of importation of those plants from distant lands.

That tree Ferns are costly in comparison with a Pelargonium is a necessity, but each year as consignments of "trunks," as the dormant plants are expressively designated, are arriving in greater numbers and in better condition, so are they offered on less costly terms than heretofore. But the real question is not what a plant costs, but, Is it worth that cost? There is a cardinal difference to be borne in mind in assessing the value of a Pelargonium and a tree Fern. The former may be worth two guineas one year, but what is it worth the next? It necessarily declines in public estimation, becomes common and devoid of interest. It is not so with such plants as tree Ferns. These increase in interest, beauty, and worth with time and cultivation. These are plants which command admiration and attention, and their extended culture is worthy of being recommended. In the furnishing of conservatories they should never be lost sight of; their noble, elegant, and refreshing appearance contributing a feature for which there is no substitute. How many structures do we enter in which we involuntarily feel that to make them thoroughly enjoyable towering Ferns and Palms are the great desiderata?

The merits of these plants are not fully recognised, or, at any rate, their cultivation is injudiciously limited. Their first cost is now by no means ruinous, and there is nothing intricate or difficult in their cultivation. They demand no great yearly outlay in coals to preserve them in health; but good soil, pure water, and a pleasant genial temperature embrace all their requirements—that is, those species which are indigenous to temperate climes; those from warmer latitudes, of course, requiring special structures, of which they are emphatically worthy, and in which a collection has a grand effect. They may be either grown in pots or tubs or planted-out, and there are few conservatories wherein one or more pairs of these plants would not add greatly to their beauty.

Some of the temperate-zoned species which are distinct and moderate in price are Dicksonias antarctica and squarrosa; Alsophilas australis, excelsa, and Leichardtiana; Cyatheas dealbata, Smithii, and princeps.

Other distinct, rare, and beautiful species there are, both for temperate and tropical temperatures, which it is not necessary to enumerate. The above are only named as typical of these plants, and the figure we publish does not so much

convey an adequate and correct idea of a species as it demonstrates by a characteristic habit of growth how eminently suited are these plants for various positions and purposes of decoration.

A soil composed of turfy loam, peat, and silver sand, a sufficiency of moisture at the root and in the atmosphere, with moderate shade and a minimum temperatnre of 45°, are the requisites of the temperate species; those from tropical latitudes requiring a minimum winter temperature of 60°, with a corresponding increase in both cases during the summer months. The whole of the species are of easy culture.—W.

IRIS GERMANICA.

On page 237 I read an interesting article on this old and beautiful garden flower. Until then I was not aware what a rich variety there is in cultivation. German Irises have been exceedingly fine this year. I have seen them flowering profusely under trees in poor soil, and immense clumps in shrubbery borders. I have seen their bright heads adding cheerfulness to churchyards, and for the past month they have been the brightest of all flowers in cottagers' gardens. They seem, in fact, to flourish anywhere, in town or in country, in rich soil or poor, in sun or in shade. For cut flowers nothing can be more suitable, and this brings me to what I have to say.

Being in London recently I saw a splendid collection of thirty varieties in the Central Avenue of Covent Garden Market. Surely every tint and colour to be found in flowers were blended in that box of blooms—blues, pinks, crimsons in every shade, with yellow and white in purity and clearness. The reticulations of these flowers were most chaste, and the delicacy of the pencilling on many of them was exquisite. Of course I shall have some of them, as I find they are offered at a reasonable price. But why are not these flowers advertised? I never see them offered anywhere, and my neighbours, of whom I have inquired, were as ignorant about them as myself. There is much ado made of flowers of less beauty. When once the distinct and splendid varieties of this fine old garden flower are known they cannot fail to be inquired after and cultivated in many gardens where they have now no place.

While I can enjoy beautiful examples of bedded-out flower gardens as well as anyone, I am still glad to see that increased attention is being given to our hardy flowers, and amongst them few are finer than these Irises, and few are less understood than are their diversified beauties and advantages.—A Countryman.

PORTRAITS of PLANTS, FLOWERS, and FRUITS.

Kniphofia Macowani. *Nat. ord*, Liliaceæ. *Linn.*, Hexandria Monogynia. Native of South Africa. Flowers scarlet, tipped with yellow.—"We have several dried specimens of this pretty little Kniphofia, collected by its discoverer, whose name it bears, in grassy places of the Boschberg mountains in Somerset district, where it inhabits elevations of 4000 to 5000 feet. It was described from these by Mr. Baker, and flowered shortly afterwards in the Royal Gardens from roots sent by Professor Macowan. It is best treated as a greenhouse plant, though probably as hardy as the other species of the genus."—(*Bot. Mag.*, *t.* 6167.)

Crocus Crewei. *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia. Native of Greek Archipelago. Flowers creamy, striped with purple and yellow.—"It is remarkable that so distinct an undescribed plant should inhabit Syra, the best known of all the Greek islands, and one which has long been the coaling station for the Mediterranean steamers, whence the traffic diverges in one direction to Smyrna, and in the other to Constantinople and the Black Sea. This fact shows how much remains still to be done towards the investigation of the bulbous plants of the Levant, and especially in respect of such genera as Crocus, whose flowers are very fugacious.

"Crocus Crewei is a discovery of the gentleman, H. G. Elwes Esq., F.L.S., to whom horticulture is indebted for the introduction of many new Oriental bulbs. He collected seeds and corms of it on hills about 1000 feet high, growing with C. Boryi, and flowering very early, and transmitted corms to the Rev. H. Harper Crewe, who flowered them at the Rectory, Drayton Beauchamp, in March of the present year. At Mr. Elwes's desire I have named it after our common friend, Mr. Crewe, whose collection of Croci is the richest in Europe."—(*Ibid.*, *t.* 6168.)

Dracæna Smithii. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia. Native of tropical Africa. Flowers yellow.—"The precise origin of the handsome Dracæna here figured is unknown; it has been in cultivation for many years both at Kew and Sion House, and it appears to be so closely allied to D. fragrans that I cannot doubt its being an African species, and one probably introduced by Whitfield from the West Coast a quarter of a century ago. As it is, all trace of its history is lost in both establishments.

"Mr. Baker, who I follow in keeping it distinct from D. fragrans, has proposed that the name of the late and present able Curators of the Royal Gardens (both named John Smith, and unrelated) should be attached to this plant, which is the more applicable, inasmuch as the present Curator had charge of the gardens of his Grace the Duke of Northumberat Sion House, where, as well as at Kew, D. Smithii has been long in cultivation. It flowers in winter or early spring in both establishments."—(*Ibid.*, *t.* 6169.)

Balbisia verticillata. *Nat. ord.*, Geraniaceæ. *Linn.*, Monadelphia Decandria. Native of Chili and Peru. Flowers yellow; anthers and pistil red.—"This beautiful half-hardy shrub was introdnced into the Horticultural Gardens in 1825; but like so many other plants requiring occasional protection to insure its continuance in the open air, it soon was lost from out of doors, and coming from a dry cool climate it damped off when transferred to a pit. Such plants, indeed, can be secured only through a constant repetition by cuttings, and by more care than is usually bestowed on plants with unfamiliar names. When properly grown it is exceedingly handsome, flowering in August and September, and resembles a gigantic Hypericum more than an Œnothera, with which latter it has more usually been compared. The Chilian name is Flor de San José, and it has a wide range, both in Chili and Peru, growing on dry hills and ascending to 10,000 feet.

"Balbisia verticillata has been introduced for the second time by Messrs. Veitch."—(*Ibid.*, *t.* 6170.)

Masdevallia Estradæ. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Flowers purple and yellow.—"Though neither so rich in colour nor grotesque in form as the species of Masdevallia lately figured in this work, the present species promises to be a favourite with cultivators from its dense habit of growth, abundant flowering, and the delicate tints of the flowers. It is a native of New Grenada, and was, according to Dr. Reichenbach's statement in the *Gardeners' Chronicle*, first observed in the garden of a New Grenada lady, Dona Estrada, a skilful grower of Orchids. It was subsequently found by Mr. Patin, collector for Mr. Williams of the Victoria and Paradise Nurseries, through whom it was thus first introduced into this country."—(*Ibid.*, *t.* 6171.)

Viburnum Sandankwa. *Nat. ord.*, Caprifoliaceæ. *Linn.*, Pentandria Digynia. Flowers white and pinkish.—"A hardy evergreen shrub, cultivated in Japan, whence we have cultivated specimens gathered by Maximovicz at Nagaski, and native ones from the Loochoo Islands, gathered by C. Wright during the American North Pacific Exploring Expedition in 1853-6, and subsequently in the same island by Dr. Weyrich, communicated from the St. Petersburg Botanic Gardens.

"It has been long cultivated at the Scilly Islands, where the late proprietor, Aug. Smith, Esq., M.P., formed at Tresco Abbey a magnificent collection of half-hardy herbs, shrubs, and trees, principally procured (and this amongst them) from the Royal Gardens, Kew, and from Messrs. Veitch of the then Exeter Nurseries. This collection is now sedulously cared for by his heir, J. Dorrien Smith, Esq., who sent to Kew to be named flowering specimens of V. Sandankwa in March last. It is not a little remarkable that a shrub, native of the Loochoo Islands, which are but little north of the tropics and within the zone of the typhoons of the Chinese seas, should flourish in 52° N. and in the cool Atlantic Ocean. At Kew it has proved hardy planted against a wall in a very sheltered place, but has never flowered."—(*Ibid.*, *t.* 6172.)

Death of Mr. Rollisson.—We regret to have to announce the death of Mr. William Rollisson, the head of the old and well-known Tooting Nursery firm, on Friday last, the 18th inst., in the seventy-third year of his age.

NOTES on VILLA and SUBURBAN GARDENING.

The Vinery.—This house will now need considerable attention, for if the Grapes are forward and commencing to colour they may with advantage have more air admitted to them; the atmosphere should also be kept rather dry than otherwise, though in the early stages of colouring it will be safe to advise

that on hot sunny days the floor and stages of the house may be sprinkled two or three times. I advise this as a preventive against the inroads of red spider, which an amateur cannot so well eradicate as a professional gardener. I do not think it proper treatment to grow the Grapes in a moist atmosphere, and then when a few berries begin to colour suddenly to withhold the application of moisture, for the healthy foliage receives a check, and if there is a little red spider in the house it begins to thrive immediately. I think we cannot speak too plainly to an amateur upon these matters, because in his usually small houses it is a question of a crop or no crop. In speaking of applying moisture, even that treatment ought to be withheld within a reasonable time, say a fortnight after colouring; then if the leaves are healthy they will carry the crop to perfection. Grapes in the above ripening stage, if they are not admitted air all night, the house ought to be partly opened early in the mornings of sunny days, say by six or seven o'clock, to prevent the condensation of moisture upon the berries, which is injurious to them if they are required to hang long; it also detracts from their appearance, because the bloom runs off and they become spotty.

Having hitherto referred to forward Grapes, which is not likely to meet all cases, I will remark on late houses in which the fruit is but just set. Here, then, thinning must be quickly completed, and if the fruit is required to hang well on into autumn allowance must be made for this by cutting out more berries, and tying up the little shoulders, which both improves the appearance of the bunch and allows a circulation of air between the berries. At the same time keep the young growth pinched back at least once a fortnight up to the time of colouring, when it may be allowed to run more freely.

Maintain a growing atmosphere at all times, and if the roots of the Vines are inside of the house the borders must be well watered, that is, not to be satisfied with a mere sprinkling, but give a good soaking, and even the outside border will be the better of a supply, especially if the borders happen to be lightly made with an abundance of good drainage and porous soil. These borders whether inside or out will take large quantities of water at three or four different times during the summer, giving the last one just before the time for colouring, and then proceed as I have directed in the first part of these notes. As to temperature, if the Vines are Muscats they must have a heat of not less than 70° at night, which will be probably maintained by the summer weather, or, if not, a little fire heat at night must be applied. Black Hamburgh Grapes and some of the common White sorts will do with a heat of 65° at night at this time of the year, allowing 5° higher for all sorts in the day, with the addition of 10° for sun heat with air on.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

IN the last reference to kitchen garden work we had to complain of the want of rain; since that time an inch and a quarter has fallen with good results.

Early Potatoes and Peas are the most important crops. The Extra Early Vermont Potato has disappointed us this year, not perhaps so much because it is not quite so early or of such good flavour as the earliest English kidney varieties, but because of very nearly half of them becoming diseased. They started well on the early borders and a patch of them in one of the fields, but nearly half has gone off with the disease alluded to in last week's Journal, leaving ugly gaps in places a yard in length. If this new disease is introduced to our fields and gardens, and the Dalmahoys and Regents are decimated as the Early Rosea and Vermonts have been this year, many hardworking farmers will wish that our American cousins had kept their stock at home. Indeed, it is doubtful if any of the sorts that have crossed the Atlantic to England either have or will give universal satisfaction. They are very well as a trade speculation, and are no doubt adapted to those who crave for something new, but they are far behind our own Regents, and cannot be named with the white kidneys.

From Potatoes it is pleasant to turn to Peas. Our vegetable principles are inclined to conservatism, but our old favourite Taber's Early Perfection has probably been sown this year for the last time, and for the earliest crops nothing will be sown but the sorts raised by Mr. Laxton of Stamford. The first sowing has been gathered; it comprised William I. and Alpha, they were ready in the order named. William I. is not only preferred in the kitchen to Taber's Early, but it is by far the best early exhibition Pea. Dr. Hogg was sown on the 27th March, and on the 17th June it was quite ready to pick; it has very handsome curved pods of a deep green colour. Unique sown on the same date was ready a day or two earlier. This will be a very fine Pea for those who have gardens in exposed situations or who cannot readily obtain sticks for the taller sorts. It does not grow more than 1½ foot high; it has very fine-looking pods. Premium Gem is splendid this year. The later sorts are much improved by the rains, which have also kept off the thrips; this pest always attacks our Peas in the summer months, and is not easily destroyed. The hoe had been well kept at work amongst the crops, but after the rains the weeds could easily be discerned; when the surface had become rather dry the Dutch hoe was run through the rows again. Cabbage Lettuce is not grown, but the Cos variety Hick's Hardy White is certainly the very best selection of the Paris White; it has been very fine and has stood well through the drought.

The young Celery plants have been eaten very much by earwigs. Young earwigs burrow in the ground in clusters by day, and come out to the work of depredation at night. A good way to destroy them is to place some dry moss in the bottom of 60-sized pots, and lay the pots on their sides near their haunts; the earwigs will hide in them, and may be destroyed in the morning. As soon as Peas come in plentifully we discontinue cutting the Asparagus, and have now done so.

PINERIES.

Some allusion was made to temperatures two weeks ago; since that time the weather has been such that we could not dispense with artificial heat altogether, although but little has been required. On mild nights the temperature will be from 70° to 75° at 10 P.M. This must not be considered excessively high for a midsummer temperature; on very hot days we have often had it up to 80° and 85° without any artificial heat at that hour, but rather than this should be it is better to leave the ventilators open all night. So far it has not been necessary to do this. If some good strong suckers of Queens could now be obtained and potted in 6 or 7-inch pots, the pots plunged in a brisk bottom heat and a high temperature kept up, under good general management they would nearly all fruit next summer from June onwards. Succession Queens that have now nearly completed their growth should have air freely admitted by day, and be cautiously watered; in a word the growth must be well matured for starting early for early fruit next season. It is quite certain that Pines may be started for fruit as soon as the growths are matured, but they are not likely to give satisfaction unless they have a season of say two months' rest. All plants have a season of rest, and the gardener who carefully studies those periods and treats his plants in reference to them is sure to be successful.

CUCUMBER AND MELON HOUSES.

It is almost a question with us whether it is not desirable to grow the Cucumbers in frames during the summer. Good houses like ours are more useful for Azaleas, Camellias, &c., where they can be placed to make their growths and have their special wants attended to without interfering with any other plants, as is the case when they are placed in vineries, where the plants are too often the medium by which red spider is introduced to the Vines. In Scotland it is necessary to resort to linings of fermenting material to maintain a sufficiently high temperature in frames; but "down south" plenty of good Cucumbers may be grown with the glass protection merely, and many prefer the Gherkins that are grown in the open fields by the acre, and of which some of the large growers cut several tons weekly in the season. All the shelter they require is from rows of Rye sown at intervals across the fields to break the force of the wind.

Melons are nearly all cut, and if anyone is anxious to notice the amazing fecundity of the red spider, an excellent opportunity is afforded as soon as syringing is discontinued to allow the fruit to ripen. Though the leaves may appear quite clean, in a week the active little Acarus will be crowding them in every part. If it had been intended to put out another crop the plants would have been ready, but the house is useful for Azaleas making their growth, and will be utilised for that purpose.

PEACH HOUSES.

In the late houses fruit will be stoning, and in some instances, perhaps, making the second swelling; in either case let the syringe, or if the house is high the garden engine, be applied with vigour. Like the Melon, the Peach tree ought to be quite free from spider when the fruit is on the point of ripening, and this can easily be done by constant syringing from the first. The roots ought to have a thorough watering when stoning is completed. Dressing the surface of the border with rotted manure before watering is preferable to using manure water. Fruit that is ripening ought to be looked over daily, and all that parts freely from the stem ought to be gathered. Hexagon netting, or, indeed, any old shading, may be suspended underneath, into which the fruit will fall. Thoroughly wash the trees and water the borders, if root-watering is necessary, in houses where all the fruit has been gathered.

PLANT STOVE AND ORCHID HOUSES.

Young hardwooded plants, such as Ixoras, Gardenias, Bougainvilleas, &c., also Ferns growing freely that were potted in the early spring months, now require to be placed in larger pots, and if they receive a liberal shift no more will be required this year. Thus a plant in a 7-inch pot may be transferred to a 9 or 10-inch pot, and the more robust-growing specimens may be shifted

into 11-inch pots. We have cut-back the climbers closely. It is certainly a mistake to allow the roof of the house to be much covered; the best specimens are obtained where no climbers are overhead.

Poinsettia pulcherrima has been removed to a cool greenhouse; the plants may even be removed to a sheltered position out of doors with advantage during the summer months. Cuttings of some of the softwooded species were put in during the spring months. They have now been potted-off, and are growing freely. Attention is now required in regard to shading and ventilating; much injury results from not opening the ventilators early in the morning. Houses that catch the morning sun ought to be attended to before six in the morning in hot weather.

Many of the Orchids are now being repotted or placed in fresh baskets. Dendrobiums that have just flowered are starting into growth. As the growths advance fresh roots are thrown out; and this is the best time to repot, or, if this is not necessary, to add fresh peat and sphagnum to the pots or baskets. Cattleyas and all other Orchids may be seen to now, as nearly all the species are rooting freely. Red spider and thrips must be watched for on Dendrobium Devonianum and many others. It may be necessary to sponge the young growths with soapy water, but the plants may be syringed daily.

Some of the Cypripediums are very subject to the attacks of thrips, C. Veitchianum, one of the scarcest and best of the C. barbatum section, particularly so. The thrips attack the centre of the young growths, and it is very difficult to destroy them without injuring the plants. Puffing tobacco smoke in is as good a method as any. Many different species of Orchids are being imported at this season, and the plants require careful management at first. It is a good plan to pot Cattleyas and Lælias amongst clean crocks, adding the peat and sphagnum when fresh roots are formed. Saccolabiums and Vandas may be suspended from the roof until roots are thrown out. Cypripediums do well if laid out on clean moss, and all of them must be sprinkled with water once a-day at least.—J. Douglas.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Wellington Road, St. John's Wood, London.—*Stove, Greenhouse, and New Plant List.*

M. Alexis Dallière, Ghent, Belgium.—*General Plant Catalogue.*

Ant. Roozen & Son, Overveen near Haarlem, Holland.—*General Bulb Catalogue.*

HORTICULTURAL EXHIBITIONS.

Secretaries will oblige us by informing us of the dates on which exhibitions are to be held.

Stowmarket.—June 24th and 25th. Mr. S. Prentice, Hon.-Sec.
Crystal Palace Company.—Rose Show, June 26th; Autumn Fruit and Flower Show, September 7th to 9th—Sec., F. W. Wilson. Bees and their appliances, September 21st to 23rd—Sec., J. Hunter.
Reigate (Rose).—June 26th. Bushby Britten, Esq., Hon.-Sec.
Hereford (Roses).—June 29th. Rev. C. H. Bulwer, Hon.-Sec.
Wisbeach.—June 30th. Mr. C. Parker, Hon.-Sec.
Maidstone.—(Roses), June 30th, at Vinters Park. H. Benstead, Esq., Hon. Sec., Rose Club, Mill Street, Maidstone.
Norfolk and Norwich Horticultural Society.—Rose Show, June 30th. E. A. Field, Hon.-Sec.
Birmingham.—July 1st, 2nd, 3rd, and 5th. Mr. Quilter, Aston Park Sec.
Spalding.—July 1st and 2nd. Mr. G. F. Barrell, Hon.-Sec.
Tunbridge Wells.—July 2nd. Mr. E. F. Loof, Sec.
Marsden.—July 3rd. Mr. J. H. Edmonton, Hon.-Sec.
Brockham Rose Show.—July 3rd. Rev. Alan Cheales and Charles Mortimer, Esq., Hon.-Secs.
Southgate.—July 3rd. John Miles, Esq., Hon.-Sec., Southgate, N.
Grantham.—July 6th and 7th. Schedules, &c., from Mr. Lyne, Bookseller.
Huntingdon.—July 7th. J. Oldman, Esq., Hon.-Sec.
Durham and Northumberland.—To be held at Elswick Park, July 7th and 8th. Mr. R. Revely, Sec.
Leicester.—July 7th and 8th. Mr. W. C. Marris, 8, New Street, Sec.
Wintebton.—July 7th and 8th. Mr. McCallum, Sec.
Frome (Rose).—July 8th. Mr. A. R. Baily, Hon.-Sec.
Kilsby.—July 8th. Sec., Mr. C. E. Bracebridge.
Richmond.—July 8th. Mr. A. Chancellor, Hon.-Sec.
Nottingham.—Rose Show, &c., July 8th, 9th and 10th. Apply to Alfred Kirk, Municipal Offices, Nottingham.
Oxford (Roses).—July 9th. Mr. C. R. Ridley, Hon.-Sec.
Grange-over-Sands—July 9th. Mr. Thomas Ashley, Sec.
Heworth.—July 14th. Mr. R. H. Feltoe, Heworth, York, Hon.-Sec.
Ogndle.—July 14th. Mr. Alfred King, Sec.
Tonsbridge.—July 14th. Mr. W. Blair, Free Press Office, Hon.-Sec.
Wimbledon.—July 14th and 15th. Mr. P. Appleby, 5, Linden Cottages, Sunnyside, Wimbledon, Hon.-Sec.
Darlington.—July 16th, at Southend. William Hodgson, Sec.
Bramley.—July 19th and 20th. Mr. R. Fox, Sec.
Brecon.—July 22nd. Mr. W. J. Roberts, Sec.
Helensburgh, N.B. (Rose Show).—July 23rd and 24th. Mr. W. Ure, Waddell, Sec.
Cleckheaton.—July 24th. Mr. S. H. Williamson, Hon.-Sec.
Bridge.—July 28th. Mr. E. Hardeman, Hon.-Sec. [Hon.-Sec.
Preston.—July 28th and 29th. Mr. W. Tronghton, 4, Church Street,
Shrewsbery.—July 29th and 30th. Mr. H. W. Adnitt, Hon.-Sec.
Southampton.—July 31st and August 2nd. Mr. C. S. Fuidge, 32, York Street, Lower Avenue, Sec.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Seedling Flowers (*R. N.*).—O! such withered specimens we can only say that the Ivy-leaved Pelargonium is darker than the parent flower, and that the Rose in form has no special merit. No useful judgment can be formed of any flower unless the habit of the plant can be seen.

Selling Garden Produce (*T. H. T.*).—We advise you to have no consideration of what you in other years sold the produce for. If you were the incoming tenant you would not submit to anyone intruding upon the ground and gathering the crops.

Osmunda regalis (*R. F. B.*).—The name "Royal" applied to this Fern is a translation of the specific name "regalis," and was evidently applied to it because it is the tallest and most handsome of our European Ferns. It has the same name in most of our continental languages. In Dutch and German it is Konigliche, king-like; in Danish, Engelregne, of similar reference; and in Spanish and Portugese the name real, kingly, is applied. Osmund in Anglo-Saxon means "house-peace," and the combined names, "House-peace royal," may have had reference to the wound-healing powers our ancestors ascribed to it.

Foreign Florists (*C. K.*).—Write to M. Vorschaffelt, 134, Faubourg de Bruxelles, Ghent, and M. M. Jules Margottin, à Bourg-la-Reine, Paris.

Strawberries Unfruitful (*T. C. J.*).—The plants not having been planted until last autumn we are not surprised at some of them not showing fruit this season, the crowns not having been sufficiently developed for flowering. We should leave them until another year, when they will probably fruit; but if you want runners for a new plantation we should take them only from fruitful plants.

Read's Melon (*R. A. W.*).—In a house this Melon does not show nor set its fruit so freely as a majority of Melons, but in a frame it shows abundantly and sets freely. We think in your case there has been a deficiency of moisture at the roots, and that the atmosphere has been too moist. It requires a rather high and dry atmosphere to secure a good set, with a good moisture in the soil. It is a fine Melon, one of the finest-flavoured of Scarlet-fleshed kinds.

Constructing a Greenhouse (*J. P.*).—You do not give us any data as to what height you can take the back but we presume it may be 13 feet, in which case we should have the width 12 feet, having 2 feet 6 inches of front and end walls above ground, and 3 feet of lights in front and the ends above the wall glass. The rafters for such a house should be 7 inches by 2½ inches, and chamfered on the under side to half their thickness, and these may be fixed 3 feet apart, and between each we should have two sashbars 2½ inches by 1¼, and chamfered on the under side to one-third the thickness. The ventilation we should provide in the upper part, having a light the whole length 18 inches wide, and made to open with crank and lever, and the whole of the front lights should be made to open. As to glass, 21-oz. sheet thirds quality is best, having the squares of 30 to 36 inch in length, and with laps not exceeding a quarter of an inch. You may have five Vines at 6 feet apart, which will not shade the house too much for plants, being no more objectionable in that respect than any other climber. Plant the Vines inside, having at least a 3-feet width of border to plant them in, and have the front wall arched so as to allow of the roots passing from the inside to the outside border.

Climbers for House (*J. C.*).—For the south-east Cydonia japonica and var. princeps, Glycine (Wisteria) sinensis, Jasminum officinale grandiflorum, and Tea-scented Roses Sombreuil, Niphetos, and Maréchal Niel, to which may be added Clematis Lucie Lemoine, Lawsoniana, and Henryi. For the west—Capriolium flexuosum, Lardizabala biternata, Jasminum revolutum, and Tea-scented Rose Maréchal Niel, and Noisettes Céline Forestier, Cloth of Gold, Lamarque, and Rêve d'Or. It may be that you want evergreens which are of neater growth, such are for south-west—Ceanothus floribundus, C. integerrimus, C. Veitchianus, Escallonia macrantha, E. glandulosa, Garrya elliptica, Berberidopsis corallina, and Magnolia grandiflora Exmouth variety. South-east, Berberis Darwinii, Cotoneaster microphylla, Crataegus Pyracantha, and Ligustrum japonicum. The best material for walls is the diamond-wire trellis fixed at from half to three-quarters of an inch from the wall, the nearer the better, providing it will allow of the tying material being passed around it.

Ferns not Thriving (*M. P.*).—The fronds you sent us were scorched, and no wonder when you have for a cold house 80 feet long only three ventilators of 4½ feet each, the temperature rising to 90°, and 100° in hot weather. The Ferns are simply roasted. It is indeed a higher temperature than is needed for stove Ferns. The ventilation you name ought to have extended the whole length of the house, and at this time of the year be left open day and night, having over the opening some wool netting, which would prevent injury from a drying current of air, as would be the case were its force not broken by some obstructive yet open material. The burrs are not good. A porous material is preferable, but it would not prevent the Ferns from growing satisfactorily, providing the rockwork is so constructed as to allow of the water escaping. It would not do any good to cement them over, only it would add immensely to the appearance. Watering with the garden engine is too heavy, and will cause them to brown under so great a heat. Whatever watering is required should be done with a watering pot or with a hose pipe, and not overhead, and the moisture for the atmosphere should be maintained by sprinkling the path, the rockwork, and other available surface morning and evening, which with the shade you name will give you all the moisture required. Ferns require a moist soil without sodderiness, and moist atmosphere, cool and shaded.

Budding Roses (*Committeeman*).—We prefer removing the wood from the shield. No. 561 contains the rules you mention. You can have it if you enclose four postage stamps with your direction.

Reinette du Canada and Northern Spy Apples—Exquisite Peach (*J. E.*).—The first-named Apple is good alike for culinary or dessert use, and Northern Spy is first-rate for cooking, but is seldom used for that purpose, it being considered too good. Exquisite Peach ripens about the middle of September, and is large and excellent.

Fuel for Stove—Tank-heating (*Idem*).—The stove you mention will burn any kind of fuel, but prefer coke or cinders, the latter or both mixed with a little small coal, or the coke broken up rather small. The stove boiler would answer well to heat a tank of the size you name, and in reference to the tank it is manifest the "flow and return should be on opposite sides of the division," which you have accurately described in your sketch.

Removing Vine Tendrils (*F. I.*).—They, as the Vine shoots are secured to the wires or walls, are of no use to the Vines, which is that of enabling them to support the shoots, hence in cultivation there is no need of this appendage, and they are, therefore, removed quite as much for appearance as for any benefit conferred by their removal. Remove them at once.

Berries of Muscat Grapes (*Six-years Subscriber*).—They are attacked by "spot," as gardeners call this ulceration. You have neglected the disease until it has become the worst instance we have seen. It is caused by defective root action. Pick-off all the diseased berries, and water copiously with tepid weak liquid manure. A Grape-grower to whom we have shown the berries says it is "scald" as well as spot, and that you must admit air very early in the morning, indeed leave on a little all night. Both roots and atmosphere are at fault, and you must be prompt in remedying both or your crop will be ruined.

Vine Leaf Spotted (*W. G.*).—There is not much the matter, but the leaf demonstrates that the foliage has received a check by a low night temperature, which has occurred possibly some weeks ago. With a genial atmosphere, damping the house several times a-day, and careful attention to ventilation, especially admitting a current of air all night, your Vines will prosper. The crushed state of the footstalk of the leaf we assume was caused in transit through the post office; beyond that there are no serious symptoms.

Vine Leaf Stained (*H. A. P.*).—The leaf sent is very deficient in substance, and cannot withstand the rays of the sun. It is suggestive also that a high night temperature has been maintained. Apply to the root tepid manure water, do not force the night temperature above 60°, leave on a chink of air at the top of the house all night, increasing it gradually as the temperature rises in the morning; close the house entirely for an hour or two each afternoon, sprinkling the floor with guano water of a strength of 1 oz. to a gallon of water, and shade slightly until the Vines gain vigour. The temperature of the house should not rise beyond 80° after being closed. The scrap of Fern was insufficient to determine the name.

Seakale Treatment (*A Regular Subscriber*).—If the stalks have been cut after blanching they will not require to be cut again during the summer, only if any show flower-stems those should be cut away as they appear. If it has not been blanched and cut as before stated it will only require to have any flower-stems removed, and those just level with the crown, from the side of which will come leaves, and crowns be formed for next year's produce. Keep clear of weeds, and water liberally with liquid manure, slops from the house highly diluted with water being very beneficial to it and Asparagus during growth.

Gosforth Horticultural Show (*Fairplay*).—There is nothing in the rules to prevent your exhibiting in either the open or the cottagers' classes, if your account of yourself is accurate.

Suspension Bridge (*W. E. B.*).—We have had no experience in erecting such a bridge, but any civil engineer could carry out your intention.

Propagating Clematises (*Forester*).—Besides grafting, they are increased by cuttings of firm side shoots—short stubby shoots taken off with a heel, and inserted in light soil in a shady position and covered with a hand-light. From now to the middle of August is a good time to put in the cuttings. The surest mode, however, is by layers in September, not detaching them until the following autumn. Another mode is to lay a ripe shoot about an inch below the soil, and from every eye almost will come a shoot, and they will form roots beneath the soil and become individual plants. The layer must not be separated from the plant. The shoot is the better of a notch about halfway through just below each eye. All the Clematis are sufficiently hardy for bedding out.

Seedling Cyclamens (*Idem*).—After they are potted off singly they should be placed in a frame having a gentle heat, or in a house with a moist heat, sprinkling overhead twice a-day, keeping them near the glass to prevent drawing, and having only moderate ventilation. This should be continued until September or October, and then, if grown in frames, the plants may be removed to a house having a warm greenhouse or cool stove temperature, keeping the plants moist, and shifting them into larger pots as required. By November they will require 5-inch pots, and in February a majority will, the treatment having been liberal, be showing flower. When in bloom they may be removed to a cooler house.

Heating Pit from Kitchen Boiler (*H. W.*).—Your boiler having a hot-water cistern at the top of the house to supply a bath-room, &c., with hot water, will not heat satisfactorily a forcing pit, the flow and return pipe for which are upon the same level as the boiler, or but slightly above it, for the hot-water cistern being at a considerably higher elevation, the water as heated will pass to the cistern, and not circulate, or very sluggishly, in the pipes of the forcing pit. You may, however, heat your house very satisfactorily by taking the return pipe from the cistern instead of directly to the boiler through your forcing pit, and with a gradual decline through the house to the boiler, the pipe not being taken below the boiler. In this way you may heat your house and always have hot water in the cistern for domestic purposes, the forcing pit being heated by the return pipe.

Names of Plants (*W. H. S.*).—Veratrum album, very vigorous. (*C. B.*).—1, Callistemon; 2, Lychnis diurna flore pleno(?); 3, Hieracium aurantiacum. (*H. H.*).—A species of Iberis, probably Garrexiana. (*J. W. S*)—Maurandya Barclayana. (*J. C. H.*).—1, Muscari comosum; 2, Orchis tephrosanthos (?). (*Mac.*).—1, Crataegus coccinea; 2, An Euonymus. (*Maurice Irwin*).—2, Pteris squilina; 3, Blechnum occidentale; 4, Cystopteris bulbifera; 5, Polypodium aureum; 6, Aspidium falcatum. (*D C., Bailey Hill*).—1 Saxifraga nizoon; 2, S. sponhemica; 3, Spiræa; 4, Alyssum. (*J. H.*).—1, Spiræa chamædrifolia; 2, Lychnis viscaria; 3, Scilla nonscripta flore albo; 4, Asplenium Adiantum nigrum; 5, Cystopteris fragilis. (*Rev. S. A. B.*).—We cannot name the Clematis from the flower only. The other plant is Anthericum liliago. (*Ladybird*).—1, Pteris cretica; 2, Davallia tenuifolia; 3, A species of Osmunda. (*Adams*).—1, A Rubiaceous plant, genus not determinable from the specimen; 2, Brassia verrucosa. (*Robert*).—Staphylea pennata, Saxifraga granulata, S. aspera, and an Acanthaceous plant not determinable. (*Amicus*).—1, Erigeron sp.; 2, E. speciosum; 3, Centaurea montana; 4, Hemerocallis flava; 5, Tradescantia virginica; 6, Iberis sempervirens. (*J. Y. J.*).—2, Myoperum; 3, Gesnera; 4, Ceratochloa unioloides; 5, Omphalodes; 6, Dicksonia. (*Henderson*).—Epidendrum virens. (*A. B.*).—We cannot name plants from their leaves only. (*M. C.*).—1, Acer saccharinum; 2, A. Pseudo-platanus; 3, A. campestre.

POULTRY, BEE, AND PIGEON CHRONICLE.

MIDSUMMER-DAY.

To-day is midsummer-day, and this is our midsummer number. We can see our chickens as we write, roaming here and there for insects, and we sigh when we think that this time last year we could have counted our chickens by scores where now we do so by half-dozens. We know other breeders are sighing too; for, in spite of those happy individuals who insist upon letting the world know that they have had better luck than ever this season, we know that it has been a bad season, and that even in very many cases where there is quantity, the quality of last year does not exist. But to-day is midsummer-day, and we will cease from any more melancholy retrospections, and bid

"Good morrow to the golden morning,
Good morrow to the world's delight."

Let us look forward rather, and speak a little of the future, and think over on this midsummer morning what we had best do to make the most of the chickens we have, be they late or early.

Recently we have had showers—almost storms of rain, which, though deadly to the rose blooms, have refreshed the earth and brightened-up the chicken runs. We suppose, however, we shall sooner or later have some of that broiling summer heat which comes in fits and starts during our changeable summers—that heat which plays the "old gooseberry" with the chickens. All have not free range for their birds, and many have not grass runs even, and when the scorching sun dries up their yards the chickens fare but badly. We would recommend such runs being plentifully watered every evening. It is surprising how it cools the ground and helps the birds. We know this idea is not new, for Mr. Wright suggested it some years ago in this Journal, and we know of many who have benefited from it.

Let us think now, too, what we will feed our chicks upon, this being most important. We are convinced change of food is a great benefit. Birds fed one week on one kind of ground food, and another week on another mixture, we find thrive admirably. We use Spratt's food extensively; but we would urge its being used judiciously with early chickens. Nothing can surpass it for giving birds a start and pushing them on; but we find when used in too great quantities it makes the combs develope too quickly, and the birds mature and so become set before they have attained the desired size. It promotes laying, too, in the pullets at too early an age. We speak here of the larger breeds, Dorkings, Brahmas, and Cochins; for the smaller varieties these results would probably not be of such consequence. We find for feeding nothing equals ground oats, ground barley, and best sharps for soft food, with Spratt's food mixed at the discretion of the feeder. We ring the changes on these, and the birds do wonderfully well. For whole corn we like wheat best, nothing surpasses a good sample of this grain for feeding. Barley and buckwheat make a good change, but wheat has our preference. Bone dust we never have used; it is, we believe, in great demand, and so we suppose is of much value in making specimens large for exhibition and pushing them on for the early chicken shows; but from such fed birds deliver us in the breeding pen. Meat, too, is no doubt used extensively in many establishments. This we have tried, but whether we went to work foolishly or not we cannot say; anyhow, after two months we gave it up, for though the birds liked it amazingly, it spoilt their taste for other foods, and, what is much more important, brought on leg-weakness. Many valuable birds while fed upon it entirely lost the use of their legs, and recovered again slowly after its discontinuance. Those who would wish to give meat a trial, or are now using it, we would recommend to make a soup of it, and then mix up the soft food with the broth; but we do not believe this extremely forcing food is at all necessary. We have had our neighbours' share of large chickens and prizes from birds solely fed, but regularly, on sound and wholesome ground and whole corn.

As regards the liquor department of our chickens, a frequent and plentiful supply of pure water is indispensable. We often dissolve a small piece of Walton's paste in the water with a very beneficial effect, and we also often mix up the soft food with boiling water in which a piece of this paste has been dissolved.

Those who have unlimited grass runs and shade of living underwood and large trees really have all that can be wanted. If they do not succeed it is their own fault. They have means and opportunities which those who only have limited and enclosed yards dare not even dream of. We do not here write for

them, but for those who have small bare yards without shade, and exposed to the rays of the sun all day. They can make good living shade by planting or sowing sunflowers and Jerusalem artichokes; it is surprising how quickly they grow, and what splendid shelter they afford. Those who keep the light-coloured breeds which are so liable to tan and burn, such as White Dorkings, White Cochins, and Light Brahmas, cannot do without some shade in the summer. Shelter afforded by doors and posts is almost useless. We want the shade of living undergrowth, beneath which the chickens can creep and rest. The sun has the same browning effect on hackle feathers as it has on the leaves.

Chickens, again, must be occupied. Those runs which are only a few yards square, and which are daintily swept over every day to make them look tidy for visitors, are useless for chickens. Nothing can grow or keep healthy in those smooth billiard-table-like runs. Chickens want to be occupied and must be kept busy. The runs must be dug up, and piles of the loose dirt thrown up one day on one side and one day on another, and the chickens will delight in levelling these. A capital way of keeping chickens on the scratch is to throw their whole corn always down among loose dirt or a lump of straw.

The sexes, too, must be separated in good time. Some breeds are more precocious than others, and so we can fix no positive date for this separation; it must depend on the breed and the breeder's experience. There is, however, another point which we think quite as important—namely, moving every little while the pullets of the larger breeds, where size is a desideratum, from yard to yard, for we are convinced it retards maturity and laying at an early age, and so greater size is procured.

Lastly, one word on exhibiting at the early chicken shows. We know when we have some promising early chickens how very tempting it is to send them to these exhibitions. The pleasure of winning is of course great, but that is nothing to the honour of being well to the front in chickens. We are certain—and we speak from experience—these shows have ruined many a noble chicken. We have had the most promising cockerel of the year literally stop growing from the date of his first show; his comb and his hackles matured, and he became set, increasing in neither weight nor size from that time. This is not a single instance; we wish it was, for hundreds can testify to the fact, and we only introduce it here as a warning to amateurs not to be too eager when they have a good chicken to have it earning its living.—W.

GRIEVANCES AND CORRESPONDENCE.

Fully agreeing with your article of last week that a great deal of unnecessary and foolish correspondence is sent to editors and secretaries, yet there are real grievances which ought to be published as a deterrent to malicious injury, and for the protection of exhibitors. Such a case, I think you will agree with me, is the following:—A friend of mine had a beautiful Game cock. It had taken several local prizes at country shows, and he was induced to send it for trial at one of the more pretentious exhibitions. He did so, and was rewarded by its taking first honours in the class for single Game cocks amongst many competitors. You will easily imagine that such an unexpected result was proudly received by my friend, and he eagerly looked for the return of his treasure, feeling that as the season was still young many subsequent triumphs awaited him. Imagine, if you can, his chagrin and vexation when, on taking the bird from the hamper, the sickle feather was found to have been broken—broken past recovery for that year. Imagine, too, his indignation when a close examination disclosed the too palpable mark of a human thumb, a certain indication that the injury had been wilful and malicious. Complaint to the committee of the exhibition brought no satisfaction. "The bird was right when put into the hamper." Amidst the doubt as to the perpetrator of the outrage, and the uncertainty as to when and where such was committed, I refrain from giving the name of the exhibition, but I can guarantee the facts to be as above stated, and, if necessary, send you the name should any doubt be thrown upon the statement.—Beta.

[The difficulty in such cases is proving who was the delinquent. The only preventive is having travelling baskets with lids so formed and padlocked that no feather can be exposed or fingers inserted.—Eds.]

HANTS AND BERKS SHOW.

Certain spots are haunted, and there are few to which reminiscences do not belong. They may be forgotten for a time, but when we see them again memory goes back, and the past returns fresh as a thing of yesterday. It was so when we approached the showyard at Portsmouth. We recollected some years since the thirty thousand people who thronged the showyard on Thursday, and as we talked of it one remarked "In spite of bad weather." That caused an "ugly pause." We had travelled to the trysting place in wind and rain. We had hoped as we journeyed things would improve, but we hoped in vain, and as we entered Portsmouth it rained faster than ever. It also blew a hurricane. We said to ourselves, "The elements will wear themselves out, and to-morrow all will be calm." The morning brought no change. We have seldom seen such a hurricane as it blew on Tuesday morning. Tents and screens were blown down, strong men could hardly stand against it, and it seemed the sole occupation of many to run after their respective hats. It is, however, the good fortune of those who have the control and management of this Show to have only recollections of success. Nothing disturbs them. Like the Captain of the Trirene, "if the wind blows hard the shorter will be the voyage; if the weather be calm it will be safer." None of the officials seemed to have any misgivings.

It is true there were large puddles of water in places, and that everything that was not protected was blown away, but the Show went on as if in halcyon times. The Judges worked in cloaks and great coats, giving their backs to the wind, and the "Royal Counties" Exhibition was, as usual, a fine display. What a change from the time when a show was held for a few hours in a field at Basingstoke! Now there were flowers, dogs, instruments of all kinds; not merely agricultural and useful, but all sorts of things of luxury—cement that made broken china stronger than it was before, hand machines that put out a fire before it had time to burn up, steam engines that could do anything but clean the drawing-room windows, seed establishments that were of themselves an exhibition, cunning contrivances of marionettes, some rowing boats, some fishing, some ringing bells, some walking about—*i.e.*, as soon as the spectator chose to obey the civil address to be read at the bottom—"Please to put in a penny, and set the machinery in motion." "*Vivat Regina*, and no money returned" thought we. Capital appliances for the gardens—terra cotta lions, Barberini and Portland vases, mignonette boxes, greenhouses that may be turned inside-out by the judicious use of two or three ropes, hand-glass frames and bells that were in reality small hothouses, tents for lawns in hot weather (glass at 48°, and wind blowing a hurricane), we could not help asking where the fireplace was; carriages so light they wanted no horse to draw them, churns that would do more with milk than ordinary ones with cream; in fact, there was everything wanted, and everything besides; a good experienced staff, and every man at his post.

The prize-list we publish will tell the names of the winners in the poultry department. Our task will, in consequence, be confined to a running comment on the different classes. *Dorkings* have fallen off in numbers, because they have improved in quality. Paradoxical as this may seem, it is not the less true. Very few agriculturists could hope for success in competing with Mr. Burnell, but we did think they could make a better fight for it. A Show of this kind should be not only an exhibition, but it should be a saleyard where profitable birds may be bought. Another, and perhaps a still more useful view of it is, that it affords an opportunity of comparing our own birds with those of others.

There were very good specimens of *Cochin-Chinas*, and the four colours—Buff, Partridge, White, and Black—were well represented. Our experience of the Blacks is not favourable. We bred these many years ago. We have tried them since. We have no difficulty in keeping Black hens, but we cannot keep a Black cock; they moult either red or white feathers. The *Game* fowls were perfect; we use the word advisedly. We have seen much worse classes at larger shows. It may be used for the Black Reds, Brown Reds, and Duckwings. Some White Game were shown, but they are never equal to their coloured brethren. Using a power placed in his hands by the liberal managers of this Show, the Judge awarded extra prizes both to Game and Cochins. The *Polands* were weak classes, but the quality of the Silvers was good. There were average specimens of *Spanish*. Among them there was the present trouble of birds with cauliflower faces that wrinkle and grow till they shut out daylight from the eye. We believe a smooth face to be one of the signal merits of a Spanish cock. The Golden-pencilled *Hamburghs* were excellent. The first-prize was almost a faultless pen. These birds are always good in these counties, but the Silvers have become worse and worse till they have suffered extinction so far as the prize-list is concerned. On this occasion both prizes were withheld. The Golden-spangled were very good. The Silver-spangled deservedly gained an extra prize. It will be seen the Spangled varieties distanced their Pencilled brethren. We are sorry for it. There is room in the United Kingdom for both breeds, and when we think on what has been done we cannot help feeling disappointed that no one will rescue these useful and handsome birds from their present neglected and retrograde position.

Brahmas, both Light and Dark, brought large classes, and many of the pens were made up of excellent birds. They had size, weight, and form. These valuable fowls have held their own during many years, and will continue to do so. They have the qualities that should commend them to every farmyard where a good hearty fowl is wanted—one that will

lay and rear and give no trouble. Game *Bantams* very good. These seem to have done much to "snuff out" the Sebrights; only one pen was shown, and that was obliged to take refuge in the Variety class. It was an excellent pen of Silvers; the dead white ground was perfect. *French* fowls were represented in each variety; good specimens of each. The Various class was strong; Dumpies, Andalusians, Silkies, Black Hamburghs, Black Polands with white tops, Malays, Indian Game, and a species of Juugle Fowl we must call "indescribable," yet we will attempt some of its leading features. First it speaks an unknown tongue more akin to a grunt or growl than we ever before heard from a fowl. The face and crown naked and the skin very red and shining; the eye dark and very small, being to all appearance partly concealed by the skin of the face being stretched over it; the beak and the appearance of the head suggesting a *mésalliance* between a Puffin and a fowl; dark plumage; the crown of the head having a seam that would seem to point to an operation such as dubbing, and we are not sure they had not been somewhat trimmed. Hen and cock very much alike. Ronen *Ducks* very weak; Aylesburys good in quality, but shown in small numbers. The Variety class deserves mention only because it contained a pair of Shovellers in good hard condition. It was formerly thought a feat to keep these alive. *Geese* were good, but it is not the time of year to show *Turkeys*.

Pigeons were strong in numbers and quality. Among the Fantails they were unusually good. Magpies deserved and received an extra prize. Some of the Homing birds were very good. The Varieties were showy, and they received an extra prize; the Barbs among them were very good.

The foreign Rabbits were more numerous than any others. The Hare Rabbits were better than common.

Dorkings.—*Coloured.*—1 and 2, T. C. Burnell, Stratton, Micheldever. 3, Mrs Radclyffe, Hyde, Wareham. *Silver-Grey or White.*—1 and 2, O. E. Cresswell, Early Wood, Bagshot. 3, Withheld.

Cochins.—1, S. R. Harris, Cusgarne, St. Day. 2, R S. S. Woodgate, Pembury, Tunbridge Wells. 3, Mrs. Radclyffe. Extra Prize, G. Parker, Fareham. *c*, H. Gibson. Brockenhurst.

Game.—*Black-breasted and other Reds.*—1, E. G. Farquharson, Blandford. 2, T. Faulkner, jun., Merston, Isle of Wight. 3, W. W. Pyne, South Lancing. *hc*, Miss S. M. Osborn, Yarnton, Oxford; J. T. Browne, St. Austell. *Any other variety.*—1, J. Beattie, Southsea, Portsmouth. 2, E. G. Farquharson. 3, J. T. Browne.

Polands.—*Golden.*—1, C. Hannen, Gosport. 2, G. J. Leony, Lewes. *Silver.*—1 and *c*, J. Hinton, Warminster. 2, G. J. Leony.

Spanish.—1, W. Bubb, Southsea. 2, E. Creese, Southsea.

Hamburghs.—*Gold-pencilled.*—1, T. Faulkner, jun. 2, G. M. Rolls, Monmouth. *hc*, J. Long, Bromley; G. F. Wheeler, Portsea.

Hamburghs.—*Golden spangled.*—1, G. M. Rolls. 2, J. K. Harris, Warminster. *hc*, J. Carr, Swansea. *Silver-spangled.*—1, J. Long. 2, J. Carr. Extra Prize, S. R. Harris, Cusgarne, St. Day. *c*, Miss E. Miller, Woodlands, Erleigh, Reading.

Brahma Pootra.—*Light.*—1, Horace Lingwood, Creeting, Needham Market. 2, T. Smith, Charlbury, Oxon. 3, H. M. Maynard, Holmewood, Ryde, Isle of Wight. *c*, J. Long, Bromley; H. M. Maynard; W. E. Fitt, Winchester; T. Smith. *Dark.*—1, Horsea Lingwood. 2, P. Ogilvie, Hambledon. 3, J. R. Way, Southsea. *hc*, Capt. A. R. Warren, Elmsworth. *c*, Miss Pasley, Moorhill, Fareham; Mrs. Dowse, Buckland, Portsmouth.

Bantams.—*Game.*—1, W. Adams, St. Clements, Ipswich. 2, F. Fielder, Southsea. *hc*, — Campbell, Furness, Westbourne; W. W. Gladwin, Tunbridge Wells; W. Adams. *Any other variety.*—1, Rev. G. F. Hodson, North Petherton, Bridgewater. 2, H. M. Maynard.

French Fowls.—*Crève-Cœur, La Flèche, or Houdans.*—1, J. H. Ward, Gussage, Salisbury. 2, Mrs. Dowse, Buckland, Portsmouth. 3, Rev. N. J. Ridley. *hc*, J. H. Ward; G. W. Hibbert.

Variety Class.—1, T. P. Edwards, Lyndhurst, Hants (White-crested Polands). 2, Rev. N. J. Ridley, Newbury (Malays). 3, J. Long, Bromley (Black Hamburghs). *hc*, Mrs. Dowse (Andalusian); O. E. Cresswell (Silkies); T. P. Edwards, Lyndhurst (White-crested Polands); W. Wildey, Cosham (Blue Andalusians); T. Norwood, Salisbury (Black and White-crested Polands); S. Howard, Southsea (Small Black Indian, Jungle Fowl); J. Hinton, Warminster (Malays).

Ducks.—*Rouen.*—1, T. Faulkner, jun. *Aylesbury.*—1, S. R. Harris, Cusgarne, St. Day. 2, T. Kingsley, Tring. *hc*, Mrs. Radclyffe. *Any other variety.*—1, L. W. Kelleway, Newport, Isle of Wight. 2, R. Wilkinson, Guildford.

Geese.—1, T. Kingsley. 2, Mrs. Radclyffe.

Turkeys.—1, Rev. N. J. Ridley.

PIGEONS.

Carriers.—1 and 2, H. M. Maynard, Holmwood, Isle of Wight. *hc*, H. Yardley, Birmingham.

Tumblers.—1, H. Yardley. 2, A. W. Pearce, Portswood, Southampton.

Fantails.—1 and 2, H. M. Maynard. Extra Prize, Miss J. Milward, Newton St. Loe, Bristol. *hc*, J. Hinton, Warminster. *c*, H. Yardley.

Tumpeters.—1, Withheld. 2, J. D. Blackman, Southampton. *hc*, W. Flanagan, Reading.

Magpies.—1, C. G. Hitchcock, Oxford. 2, A. P. Maurice, Bourton, Bath. Extra Prize, T. Homes, Lower Sydenham.

Homing.—1, G. Parker, Fareham. 2, G. H. Billet, Southampton. 3, H. Dacre, Winchester. 4, E. G. Charpentier, Portsmouth.

Any other Variety.—1, H. M. Maynard (Black Barbs). 2, T. Homes. Extra Prize, W. H. Boys, Fareham (Dragoons). *hc*, S. Howard, Southsea (Pouters); W. H. Boys. *c*, J. Lush, jun., Salisbury (Blue Dragoons).

RABBITS.

Longest Ears.—1, G. Hill, Winchester. 2 and *hc*, R. Bright, Reading.

Foreign.—1, P. Ogilvie, Hambledon. 2 and *c*, G. Hill. Extra Prize, J. Ellis. *hc*, F. Currey, Southsea; P. Ogilvie.

Any Variety.—*To include all points.*—1, R. Bright, Reading. 2, G. Newman, Winchester. *hc*, G. Hill.

Extra Stock.—*hc*, W. B. Boxall, Strathfieldsaye; G. Tubb, Basingstoke.

Judge.—Mr. J. Baily, London.

Preserving Eggs.—In America paraffin is now coming into use for covering the shells of eggs as a preservative. 2 lbs. weight of the paraffin are sufficient to preserve three thousand eggs for several months; the eggs must be operated upon when fresh; when they will shine like ivory. Not the slightest taste of the paraffin is detected.

THE THORNE EXHIBITION OF POULTRY AND PIGEONS.

Although this Show has been held annually for the last twenty-three years, there cannot be a doubt that for general good quality none have exceeded the one just concluded. The grounds in which it took place are exceedingly beautiful, and the arrangements were of a most satisfactory character, with the exception of the fact that the pens were placed entirely in the open field, consequently the poultry and Pigeons were quite exposed to the violence of the thunderstorms that prevailed at intervals throughout the day. The entry of poultry was about three hundred pens, and in this division of the Show Mr. Hewitt officiated.

There were some grand specimens of *Dorkings* shown, the dark-feathered birde being decidedly the most praiseworthy. The entries of *Spanish* were unusually good, even when contrasted with the classes of this fashionable variety as we find them at our largest poultry exhibitions. The first and second-prize Spanish cocks were a very close run; and in the class for Spanish hens seven or eight stood side by side that required a lengthy inspection by the Judge before the prizes were finally awarded. Strange to say, in the Selling class the winning birds were also Spanish, and of a quality quite equal to those just referred to. In *Cochins* many were grand specimens, the Buffs and Whites particularly so. Want of high condition, however, mostly prevailed among the Buffs, as might have been reasonably expected so late in the season. In the *Brahmas* the Light-feathered birds were decidedly bad; but the Dark birds made ample amends, more particularly the hens, and the pencilling of some of them was quite equal to that of any show of late years. *Game* fowls, throughout well shown, were very excellent even classes, the Brown Reds and Red Piles being especially fine-feathered, and the Black Reds were also in very high condition. A Variety class for cocks brought out a splendid Silver-spangled Poland, a Black Hamburgh, and a Golden-spangled Poland of highest character as the prizetakers, in the order named. The *Bantams* as a whole greatly lacked condition, with perhaps the exception of the Red Piles and the Black. A very good Pekin Bantam hen was shown among them, apparently in a dying state. The *Geese, Turkeys*, and fancy *Ducks* were superior, the latter especially so; Whistling Ducks, Mandarins, and Chilian Pintails taking the prizes in the order named, and but rarely are three pens so excellent seen together. This Show received a very general support from not only the residents but also parties from a distance.

Dorkings.—*Cock.*—1, J. Walker, Spring Mount, Rochdale. 2, W. Roe, Newark. 3, W. H. Crabtree, Levensbulme, Mancheater. *hc*, J. Blanchard, Driffield. *Hen.*—1, J. Walker. 2, W. H. Crabtree. 3, J. H. Rockett *hc*, W. Roe; R. Carr, Whitby. *c*, W. Harvey.

Spanish.—*Cock.*—1 and Cup, J. Boulton, Bristol. 2, H. Beldon, Goitstock, Bingley. 3, R. Newbitt, Epworth *hc*, J. Powell, Bradford. *Hen.*—1, R. Newbitt. 2, E. Brown, Sheffield. 3, J. Thresh, Bradford. *hc*, J. Thresh; R. Newbitt; J. Boulton; H. Beldon. *c*, J. Powell.

Cochins.—*Cinnamon or Buff.—Cock.*—1, Urwin & Iheston, Whitby. 2, Clark and Pennock, Whitby. 3, E. Winwood, Worcester. *hc*, J. Walker, Rochdale; R. P. Percival, Northenden (2); G. Blakey, Driffield. *c*, W. Mitchell, Birkenshaw. *Hen.*—1, W. H. Crabtree. 2, H. Robinson, Sheffield. 3, R. P. Percival. *hc*, J. Walker; A. Spencer; W. Harvey; G. F. Umpleby, Boroughbridge. *c*, J. North, Fartown, Huddersfield.

Cochins.—*Any other variety.—Cock.*—1, W. Whitworth, jun, Longsight, Manchester 2, W. H. Crabtree. 3, J. Walker. *c*, Rev. R. Story, Lockington Vicarage, Derby; Mrs. F. Bacon. *Hen.*—1, W. Whitworth, jun. 2, R. P. Percival. 3, Mrs. F. Bacon.

Brahmas.—*Dark or Light—Cock.*—1, W. Schofield, Birkenshaw. 2 and *hc*, T. F. Ansdell, Cowley Mount, St. Helens. 3, W. Whiteley, Sheffield. *Hen.*—1, Cup, and 2, T. F. Ansdell. 3, W. Whiteley. *hc*, R. P. Percival. *c*, W. H. Crabtree.

Game.—*Black Red—Cock*—1, E. Winwood. 2, J. A. & H. H. Staveley, Tipthorpe, Driffield. 3, H Walker, Gomersal. *Hen*—1, T. Sales & R. Bentley, Crowle. 2, J. Mason, Worcester. 3, E. K. Fox, Bradford.

Game.—*Brown Red.—Cock.*—1, F. Sales & R. Bentley. 2, H. E. Martin, Sculthorpe. 3, E. Winwood. *hc*, R. Pearson, Swansea; Webster & Adams, Beverley. *Hen.*—1, F. Sales & R. Bentley. 2, Dr. Cameron, Epworth. 3, W. Perrin. *hc*, C. H. Wolff.

Game.—*Duckwing, or other Grey or Blue.—Cock.*—1, F. Sales & R. Bentley. 2, J. Mason. 3, Webster & Adams. *hc*, J. A. & H. H. Staveley; W. Whitworth, jun. *Hen.*—1, F. Sales & R. Bentley. 2, Webster & Adams. 3, J. Wright. *c*, G. Holmes, Great Driffield.

Game.—*White, Pile, or any other variety.—Cock.*—1, Pickering & Duggleby, Driffield. 2, R. Walker. 3, H C. & W. J. Muson. *Hen.*—1, H. C. & W. J. Mason. 2, Pickering & Duggleby. 3, E. Winwood.

Hamburghs.—*Gold or Silver-spangled.—Cock*—1 and 2, H. Beldon. 3, J. H. Rockett. *Hen.*—1 and 2, H. Beldon. 3, Ashton & Booth, Broadbottom, Mottram.

French.—*Cock.*—1, W. Cutlack, jun., Littleport, Isle of Ely. 2, W. H. Crabtree. 3, W. Whitworth, jun. *hc*, G. W. Hibbert, Godley; D. Grant, Bradford. *Hen.*—1, W. Cutlack, jun. 2 and 3, H. Grant, Bradford. *hc*, G. W. Hibbert; W. H. Crabtree; E. Brown. *c*, W. Whitworth, jun.

Any other Distinct Variety.—*Cock.*—1, H. Beldon. 2, J. Kellet. 3, A. and J. H. Silvester. *hc*, S. G. Hepplethwaite; J. Jackson. *Hen.*—1, H. Beldon. 2, A. & W. H. Silvester. *hc*, P. G. Hibblethwaite.

Game Bantams.—*Black Red.—Cock.*—1, R. J. Hartley, Altrincham. 2, A. Sugden. 3, W. F. Entwisle, Westfield, Bradford. *c*, W. Roe; A. Smith, Northowram; E. Jennings, Stanningley. *Hen.*—1, Mrs. Dale, Rawcliffe, Selby. 2, A. Sugden. 3, R. P. Plumptree.

Game Bantams.—*Any other variety.—Cock.*—1, R. Newbitt. 2, A. C. Bradbury. 3, G. Dawson, Epworth. *hc*, W. F. Entwisle; G. Lewes, Swansea; F. Sales, Crowle; Bellingham & Gill. *Hen.*—1, W. F. Entwisle. 2, Bellingham & Gill. 3, Mrs. Dale.

Bantams.—*Any variety not Game.—Cock.*—1, J. Mays, Gloucester. 2, H.

Beldon. *s*, A. & W. H. Silvester. *he*, A. C. Bradbury. *Hen.*—1, H. Beldon. 2, A. C. Bradbury. 3, A. & W. H. Silvester. *he*, A. Smith.

DUCKS.—*Aylesbury or Rouen.*—1, E. Snell, Barrowden, Stamford. 2, J. Walker. 3, W. Fell, Adwalton. *Any other variety.*—1, H. Yardley, Birmingham. 2, A. & W. H. Silvester. 3, J. Walker.

GEESE.—1, J. Walker. 2, J. Hepworth, Hatfield. 3, T. J. Crowcroft.

GIBS.—1, G Fillingham. 2, O. H. Young, Driffield. 3, A. J Wells, Hatfield.

SELLING CLASS.—1, J. Fowell. 2, R. Newbitt. 3, H. Robinson. *he*, Rev. R. Story, Derby (2); T. C. Newbitt, Epworth. *c*, W. Mitchell; R. Newbitt; W. Perrin.

PIGEONS.

CARRIERS.—*Cock.*—1 and 3, E. Horner, Harewood, Leeds. 2, H. Yardley. *he*, J. Walker. *c*, H. Brown, Walkley. *Hen.*—1, H. Yardley. 2, E. Horner. 3, J. Walker.

POUTERS.—*Cock.*—1, W. Harvey. 2 and 3, J. Hairsine, Hull. *hc*, E. Horner. *Hen.*—1, W. Harvey. 2 and *c*, E. Horner. 3, J. Blanchard. *he*, J. Hairsine.

TUMBLERS.—1, H. Yardley. 2 and 3, A. & W. H. Silvester. *hc*, E. Horner; H. Yardley; Webster & Adams. *c*, Webster & Adams.

JACOBINS.—1, J. Blanchard. 2 and 3, T. Holt, Bradford. *he*, W. Harvey; J. Blanchard; E. Horner.

NUNS.—1 and 2, E. Horner. 3, T. Green. *he*, Rev. A. J. Brooke; H. Yardley. *c*, Rev. A. J Brooke.

TRUMPETERS.—1 and 2, W. Harvey. 3, E. Horner.

TURBITS.—1 and 3, H. Yardley. 2, G. Richardson. *he*, E. Horner; A. & W. H. Silvester (2).

FANTAILS.—1 and 2, J. Walker. 3, J. F. Loversidge.

BARBS.—1 and 2, H. Yardley. 3 and *hc*, E. Horner.

DRAGOONS.—1, 2, 3, and *vhc*, R. Woods, Driffield. *he*, H. Yardley.

ANTWERPS.—1, W. F. Entwisle. 2 and 3, W. Harvey. *hc*, E. Horner; W. F. Entwisle; H. Yardley.

MAGPIES.—1, E. Horner. 2, J. Blanchard. 3, M. Ord, Sands, Sedgefield, Durham.

ANY OTHER VARIETY.—1, E. Horner. 2, H. Yardley. *he*, G. Richardson; M. Ord; A. & W. H. Silvester (3); W. Harvey.

SELLING CLASS.—1, H. Yardley. 2, J. Blanchard. 3, A. & W. H. Silvester. *hc*, E. Horner; H. Brown; A. & W. H. Silvester.

Mr. Edward Hewitt judged poultry, and Mr. Cannon the Pigeons.

YORK BIRD SHOW.

YORK Summer Cage-bird Exhibition, the first Show of any great importance to fanciers since the one held at the Crystal Palace, took place in the Bootham Field, situated on the outskirts of the ancient city, on the 16th, 17th, and 18th instant. It is true that several bird shows on a less scale have recently been held at Epworth, Bedlington, Rugby, and Crowle, but at each the classes were limited. At York no less a number than thirty-seven classes were named in the very good schedule sent forth, which had the effect of bringing out of their shells some of the leviathan fanciers, who exhibited in full force, notwithstanding the enormous price of Canary seed. We could not help noticing that in a great number of the cages not a single grain of Canary seed was to be seen, and in other instances only a moderate supply, thus bearing out the remark we have before made, that Canaries and many other cage birds are not so much dependant upon Canary seed as was formerly believed. It was only in a very few cages that Canary seed was abundantly provided, and the birds appeared no better in health and condition than those having to content their appetites with millet, rape, hemp, linseed, groats, and cake.

The Show took place in a large marquee, and was well patronised by the fancy of York and surrounding towns. Some of the champion birds of last season were sent to the post, and succeeded in gaining further laurels. The portion of the Exhibition where the young birds were shown was very interesting, there being several very fine specimens present. Mr. Oxberry of Nunnery Lane, York, the winner of the extra prize, exhibited a fine, large, and elegantly-constructed breeding-cage, containing an interesting family of birds five days old. The old hen, without the least fear whatever, sat upon her young in the nest during the entire Show. The care and attention bestowed by the parents to the young brood during the time the marquee was thronged with visitors attracted a good deal of attention, and to the juvenile visitors especially was most interesting. Mr. Calvert of York also exhibited a curious specimen of an Indian cage, containing a couple of Java Sparrows. Mr. Wand of York also contributed a musical birdcage, which occasionally struck up "The Campbells are Coming," with the air of the tenant in the cage, whose periodical and somewhat incessant hopping caused a wheel to revolve and produce the tune. Another noticeable feature, and somewhat novel too, was a pattern show cage exhibited by a York fancier, whose name we failed to obtain. The cage was of the ordinary size for a show cage, and one very good point about it was that the front was so constructed that it could be slid upwards (an advantage certainly for cleaning the inside instead of unscrewing) without interfering with the two cross perches, which screwed into the back of the cage, each perch being secured at the behind part with a wooden nut. An upward sliding door or entrance was made at one of the sides, thus preserving the wired front of the cage from any impediment. Mr. Wilson, the Honorary Secretary, and his assistants did their duty well. The following are the awards :—

BELGIANS.—*Clear Ticked or Yellow or Buff.*—1 and 3, — Forth, Pocklington. 2, L. Belk, Dewsbury.

NORWICH.—*Clear Yellow.*—1, Cleminson & Ellerton, Darlington. 2, J. Calvert, York. 3, J. Stevens, Middlesborough. *Clear Buff.*—1, J. Adams, Coventry. 2, — Burton, York. 3, Cleminson & Ellerton.

NORWICH.—*Evenly-marked Yellow or Buff.*—1, G. Gayton, Northampton. 2, G. & J. Mackley, Norwich. 3, J. Bexson, Derby. *Ticked or Uneven-marked Yellow or Buff.*—1 and 2, J. Adams. 3, Cleminson & Ellerton.

NORWICH.—*Crested Yellow or Buff.*—1, G. & J. Mackley. 2 and 3, F. Woodward, Derby. *Even-marked Yellow or Buff.*—1, G. & J. Mackley. 2, Petty and Cuss, York. 3, R. J. Smith, York.

YORKSHIRE.—*Clear Yellow.*—1, J. Thackray, Great Horton. 2, J. H. Shepherd, Beverley. 3, G. Simpson, York. *Clear Buff.*—1, L. Belk. 2, T. Carliss, York. 3, — Burton, York.

YORKSHIRE.—*Evenly-marked Yellow or Buff.*—1 and 3, L. Belk. 2, W. & C. Burniston, Middlesborough.

CINNAMON.—*Jonque* —1, J. Adams 2, Cleminson & Ellerton. 3, S. Tomes, Northampton. *Buff.*—1 and 2, J. Adams. 3, S. Tomes. *Ticked or Marked Jonque or Buff.*—1 and 2, J. Adams. 3, R. Pearson, Whitby.

LIZARDS.—*Golden spangled.*—1, Holdsworth & Oliver, Harrogate. 2, S. Bunting, Derby. 3, Cleminson & Ellerton. *Silver-spangled*—1, S. Bunting. 2, Cleminson & Ellerton. 3, T. M. Reid, Halifax. *Gold or Silver-spangled with broken cap, &c.*—1, S. Bunting. 2, Cleminson & Ellerton. 3, J. Adams.

MULES—*Yellow or Buff Goldfinch.*—1, S. Bunting. 2, J. Stevens. 3, J. Adams. *Dark Goldfinch.*—1, R Hawman, Middlesborough. 2, S. Bunting. 3, J. Cowl, York. *Any other variety.*—1, J. Bexson. 2, J. Stevens. 3, W. & C. Burniston.

SELLING CLASS.—1, J. Adams. 2, F. Woodward. 3, S. Tomes.

BRITISH OR FOREIGN BIRDS.—*Best collection of not less than twelve varieties.*—1, Mrs. Calvert, York. 2, J. Calvert.

PARROTS.—1, Miss English, York. 2, S Bunting. 3, — Thorpe, York.

BRITISH BIRDS.—*Goldfinch.*—1, — Forth. 2, T. Cleminson, Darlington. 3, Cleminson & Ellerton. *Bullfinch.*—1, W. & C. Burniston. 2, — Burton. 3, Mrs. Bramley, York. *Linnet.*—1, R. Pearson, Whitby. 2, J. Dickinson. 3, — Batchelor. *Any other variety.*—1, W. Garbutt, York (Starling). 2, J. E. Barr, York. 3, W. & C. Burniston.

EXTRA PRIZE.—*Bird and Cage.*—1, — Oxberry, York.

BIRDS BRED IN 1875.

The following ten classes were devoted to Canaries bred during the present season, clothed in their nest feathers, and the competition in most instances was spirited. Many fine promising birds were exhibited :—

NORWICH.—*Yellow.*—1, J. Taylor, Hull. 2, W. Havers, Norwich. 3, G. & J. Mackley. *Buff.*—1, Harland & Son, York. 2, — Burton. 3, Miss Burton. *Even-marked Yellow or Buff.*—1, Mrs. Calvert. 2, T. Armstrong, Durham. *Dark-crested Yellow or Buff.*—1, S. Stratford, Northampton. 2, J. Smith, York. 3, R. J. Smith, York.

NORWICH.—*Nest of Yellow.*—1, T. Humphrey, York. 2, Harland & Son. *Nest of Buff*—1, T. Humphrey. 2, Harland & Son. 3, — Burton. *Nest of Crested.*—1, J. Jarvis, Scarborough. 2, W. Lazenby, York. 3, Harland & Son.

NEST OF LIZARDS.—1, S. Bunting. 2, Snowdon, Leeds.

CANARIES.—*Cage of Six Varieties.*—1, Mrs. Calvert. 2, W. Howard, Harrogate. 3, J. Jarvis.

JUDGE.—Mr. Geo. J. Barnesby, Derby.

SILVER-GREY RABBITS.

FOR the last few years the exhibition Silver-Greys have assumed a shade too dark, and many of them have had very dark heads, feet, and tail, which did not represent in colour and proportionately the true silver shade. Mr. Firth maintains, and I think he is right, that a Silver-Grey should not be of the dark shade, because that is not indicative of the silvery shade, and the difficulty is in producing the proper light silvery shade, whilst the dark shade is numerous.

Not long ago Mr. Hudson held a contrary opinion, but his specimens are none of the too light shade—an extreme as objectionable as the too dark shade, and the tendency of breeding the Silver-Greys now-a-days too light is through the instrumentality of Mr. Firth, although his specimen which successfully figured in the exhibition pen possessed, in my opinion, the exact proportionate blue tint throughout the silvery shade. I would recommend Silver-Grey breeders not to breed their specimens too light, but with the beautiful blue-tinted shade which by proper and judicious selection can be unmistakeably accomplished. Mr. Firth contends that a very dark Silver-Grey doe paired with a light-shaded buck will rarely if ever give offspring of the proper exhibition shade; but dark does, possessing the sharp, silvery, proportionate shade paired with a too light shaded buck, seldom or ever give offspring of an inferior shade, and this information coming from a breeder of experience should be of sufficient weight to encourage breeders to adopt such a selection of breeders.—G. R. SAVAGE.

THE CARRIER PIGEON—ITS INSTINCT.

THE Carrier Pigeon is becoming more than ever an object of attention, since the Pigeon societies have multiplied to that extent that nearly all our villages possess their own. Also one counts by hundreds of thousands the number of these winged messengers that from Belgium they annually transport to distances more or less remote. Monsieur Dr. Chapins, member of the Belgian Academy, has published upon this subject an excellent work entitled "The Instinct of the Carrier Pigeon, and the Means of Perfecting It."

By what means, by virtue of what faculties, are our aërial travellers able to regain their chosen home? Some have given it the name of instinct, which explains nothing; others have the idea that the Pigeon is endowed with a sensibility so great that he is able to find a guide in the difference of the density of the various currents of the atmosphere. They affirm that the Pigeon always directs itself from south to north, or better, that he rises to such heights that his sight determines his direction. These are the allegations that M. Chapins contests, without having, however, the pretence of giving the solution of the problem. In the end he treats of the organisation of the Pigeon, the capacity and delicacy of its organs of sense, and finally its faculties natural or acquired.

The organisation of the Pigeon is that of all birds in general, and in the natural order it forms the connection between Swallows and the gallinaceous tribe. It holds the first by its sustained flight, and the second by the facility with which it walks upon the earth. As to the organs of sense, one does not observe an essential difference between the Pigeon and other birds in general. The judgment and taste are with it little developed, and the same with sense of smell; but as to the hearing and sight, it is greatly favoured. However, does the perfection of its sight suffice of itself to explain the faculty of correctly directing its flight? In the examination of this last question he strives first to determine to what height the Pigeon takes its flight when set at liberty in a distant location, afterwards to discover if the objects are distinctly seen through the vapours that arise from the earth. Thirdly, the question is how it can discover often from a distance of 200 or 300 leagues, and if the curvature of the earth does not perhaps raise a barrier to the sight of a point to be obtained. It is true that a Pigeon liberated at some distant point rises from a general to a sufficiently greater height, and it is probable that it thus maintains itself in the course of its voyage. It is also probable that this height does not exceed 1000 feet, from thence what sight unrolls to its view? It results from the reasoning of the author (based upon the ascension of Mont Blanc), that supposing the Pigeon was able to elevate itself to 4810 metres, and that its sight equals that of man's aided by the best optical instruments, its view in a given direction does not exceed 52 leagues and 4 kilometres; but now we see that it does not attain even a fourth part of that altitude. Then it has for this distance much to overcome with the curvature of the earth, which we mentioned before as an obstacle to the sight, and it has again the clouds, the rain, &c, all causes which obscure the atmosphere. Therefore in the presence of these considerations we are separated from the suppositions that the sight alone directs the travelling Pigeon.

Here presents itself an objection, which is that those Pigeons before being transported to considerable distances have already made short flights, and that thus they are able very well, from point to point, to direct themselves by sight towards the goal to be reached. This objection fails with those Pigeons which have not performed the trial of some leagues, but are taken at once to points more distant, and from thence returned. On the other hand, we cannot admit that the Pigeon follows always the same route, considering that account must be taken of the influence of the wind on Pigeons the same as migratory birds.—(*American Fanciers' Journal.*)

THE BOSTON POULTRY EXHIBITION.

A GREAT deal of care and attention has been displayed by the Boston Committee in the arrangement of this year's Show. The tent was one of the best we ever saw, and the pens were so placed that an equality of light was enjoyed by every specimen. Every possible precaution was made against accidents of any kind, and no person under any pretence whatever was admitted during the time the Judges were making their awards.

Messrs. Simpson & Dodds and Mr. Crabtree had it all their own way in the Grey *Dorkings*, with very high-class birds. In *Cochin* cocks the cup-winner was a magnificent White shown by Mr. Whitworth, who also won first with a hen of the same colour. Light *Brahmas* were very good, but some of them were sunburnt. Dark Brahmas were unusually good in colour and also in feather for the season of the year, the pencilling of most of the hens being perfection itself. In so small a collection as the one at Boston we never remember seeing so much high quality in *Hamburghs*, the Spangled, both Gold and Silver, being shown in the greatest condition. Of the Pencilled birds, the Golden were unquestionably the most perfect. The *Game* classes afforded a perfect treat to visitors, as some of the best strains were entered, Mr. Fletcher winning the cup with a most valuable Black Red, Mr. Martin running very close with a Brown Red as second. Mr. Walton won first also with a truly hard-feathered Red Pile. The *Bantams* were strong in entries, and to a lovely Silver-laced Sebright hen the cup was awarded. Mr. Leno was the winner of this premium. There were separate classes for *Houdans* and *Crève-Cœurs*, and the cup for these breeds was won by the latter variety, the entries being both heavy and uniformly good. The *Spanish* classes were alone worth the trouble of a long journey by any amateur. Both the winning cocks were first-class birds, which did much credit to Mr. Newbitt's management, for they were in excellent plumage. The hens were a large class, and an equality of condition marked this class generally.

A lovely summer day ensured a large attendance, and no doubt exists that this will prove itself one of the most successful Shows ever held in Boston.

DORKINGS.—*Cock.*—1, Simpson & Dodds 2, W. H. Crabtree. *Hen.*—1, W. H. Crabtree. 2, Simpson & Dodds. *hc*, W H. Crabtree; W. Morfitt.
COCHINS.—*Cock.*—1 and Cup, W. Whitworth, jun. 2, W. H. Crabtree. *hc*, H. Tomlinson. c, C. Wilson; E. Walstow. *Hen.*—1, W. Whitworth, jun. 2, W. H. Crabtree. *hc*, C. Wilson H. Tomlinson

BRAHMAS.—*Light.—Cock.*—1, W. H. Crabtree. 2, P. Haines. *hc*, W. Harvey. c, C. Wilson. *Hen.*—1, J. Long. 2, Mrs. Peet. *hc*, P. Haines. c, W. Thorn.
BRAHMAS.—*Dark.—Cock.*—1, W. H. Crabtree. 2, Rev. J. D. Peake. *hc*, J. F. Smith. *Hen.*—1 and 2, Rev. J. D. Peake. *hc*, W. H Crabtree; J. F. Smith.
HAMBURGHS.—*Golden spangled.—Cock.*—1 and Cup, T. Blakeman. 2, J. Long. *hc*, H. Pickles. *Hen.*—1, T. Blakeman. 2, W. Driver. *hc*, W Tickner; J. Long.
HAMBURGHS.—*Golden-pencilled.—Cock.*—1, W. Tickner. 2, W. Driver. *hc*, J. Long. *Hen.*—1, C. Judson. 2, Smith & Taylor. *hc*, E. Ayre; — Driver. c, — Snell.
HAMBURGHS.—*Silver-spangled.—Cock.*—1, H. Pickles. 2, J. Long. *Hen.*—1, J. Long. 2, H. Pickles.
HAMBURGHS.—*Silver-pencilled.—Cock.*—1, H. Pickles. 2, No competition. *Hen.*—1, H. Pickles. 2, No competition.
GAME.—*Black or Brown-breasted Reds.—Cock.*—1 and Cup, J. Fletcher. 2, H. E. Martin. *vhc*, J. Jeken. *Hen.*—1, J. Fletcher. 2, H. E. Martin. *hc*, J. Jeken; J. F. Walton; R. Whitton.

SELLING CLASS.—1, W. Greenfield (Black Carriers). 2, C. Norman (Barbs). 3, J. T. Allen (Black Barbs).

Mr. Edwd. Hewitt was the Judge for poultry, and Mr. Massy for Pigeons.

BEE FEEDING; OR, SUGAR-AND-WATER VERSUS HONEY.

I HAD no idea when I wrote those few lines on the above subject that I should be handed over to the old veteran Pettigrew to be stung with his pen. However, I am not much hurt, for, like the bees, if they do sting now and then, we reap advantage from them; so I have from his remarks.

No doubt feeding is profitable at times, but with me I never began with bees for profit. I kept them because I liked to see them; I admire their industry. I never fed them as a rule, nor did I ever destroy them. I contented myself with a little honey from supers, but lately I have been forced as it were to read more about them, and seeing how much interest is taken in bees by so many, and the manis for new-fashioned hives, I have been a little drawn out. But when I read of sugar being made into honey I felt taken aback, and with Mr. Pettigrew's explanation I am no more satisfied than you can guard against foul play in competing for prizes, except, of course, it is admitted that any means may be used to produce results.

Mr. Pettigrew says, "Syrup made of sugar and water cannot be converted into honey." Naturally, perhaps, it cannot; but if bees are stuffed with it at all times what becomes of it? It is true he does say something of converting sweets into combs for breeding in; but the question is, Do they never store the syrup away with the honey?

I can plainly see that those who intend competing for prizes must work at feeding, and that to a very great extent if they hope to win.

On this question of bee-management either for pleasure or profit there is much to learn.—J. C., *Brentford.*

OUR LETTER BOX.

Non-sitting Fowls (*Fidgit*).—The vagaries you speak of do not belong to the non-sitting breeds. The first habit you mention may be attributed to the fact you mention. We cannot imagine the cause of the other unless she is in company of the more fortunate breeds, who are blest with "all a mother's gentlest cares," and plays at maternity. Feather-picking is common to Houdans in confinement at this time of year. The hen will shortly give up the habit, and will not take to it again till this time next year. If allowed her liberty she will never take to it at all. The laying you mention is excellent. Hens lay more eggs than it is supposed, but they do not always reach the right owners. You may introduce a new breed, and guard them with cerberean vigilance, but you will soon see them all over the country. This does not of necessity arise from dishonesty, but from hens laying about.

Poultry-yard (*T. K.*).—You do not give enough information. Does your place show all the space you have at command, or is there any outlet beyond the two roads that form your boundaries south and east? Assuming that there is not, we think you may keep a cock and eight hens. It would be necessary to their comfort to have the paving removed. Fowls will not do on paving stones; they get cramped and they cannot scratch. The manure heap is a help. If half the stone flooring of the barn were removed it would make a capital place for the fowls in wet weather, being earth covered with sand or grit. If they have any other outlet the numbers kept may be doubled or tripled. The essential is that they should have access to grass in some way, and that they should not be compelled to live on stones. Nothing is more useful for poultry than a barn, but it must have an earthen floor.

Insects in Hen House (*J. R. W.*).—The insects found in such quantities in your hens' nests and on the eggs, and hanging in clusters to the roof of your hen house, are the well-known Acarus (Dermanyssus) gallinæ, a fowl mite figured by De Geer MS., vol. vii., pl. 6, f. 13, and by Herrick Shaffer, No. 137, f. 14. The house wants thoroughly cleansing and washing with hot lime water. Gas-tar water and boiling water should also be freely used.—I. O. W.

Fowl's Legs Scaly (*I. C.*).—It is only of late years we have known the disease. It first appeared at Liverpool on a Cochin-China hen, at a time when the ground was covered with snow for some weeks. It was thought when the snow went the disease would go with it. It did not, for it was soon heard of in all directions. At first only old birds had it. Last year it appeared among chickens. Till that date only birds in confinement suffered from it, but now there are cases (few at present) among those at liberty. We have had to kill birds this year because the disease was so frightful. It is difficult to watch and treat it where many hundreds of fowls are kept, but we have made head against it in some instances by softening the legs and scales frequently with sweet oil or citrine ointment.

Rabbit's Eye Inflamed (*G. H. R.*).—Bathe the eye frequently with cold water.

Green Prize Cards.—Mr. Firth says that a green prize card *was* put into the basket with his prize buck and that the buck ate it, also that a Himalayan doe died from a similar cause. Let these facts warn committees from using green cards.

Taking Honey (*F. J.*).—Your idea of using an adapting-board above an eke cannot be carried into practice with advantage, for an eke is generally filled with broodcomb, and the honey goes to the hive above. Very little honey could be obtained from ekes cut from their hives, even in the best of seasons. Ekes enlarge hives and give the bees room to live and breed. If you use an eke 10 inches deep with an adapting-board it becomes a nadir, and may be used as such. The most of the honey will go to the upper hive, making it too heavy for keeping; but the nadir may receive all its bees and be kept as a stock hive. Eking is the simplest and best mode of enlarging a hive for honey; nadiring is adopted when both honey and a stock hive are wanted; and supering is resorted to for honeycomb.

Bees not Swarming (*C. M. Major*).—We advise you first to remove the super from your hive and drive all the bees out of it into the hive itself. Smoke applied at the top will drive the greater part of the bees down from the super before it is removed, or the bees may be driven by drumming after it is cut off, and then cast back on the front of the hive. If you want another super filled instead of a swarm, place a larger one on the hive to prevent swarming. If you prefer a swarm to another super, the removal of the present super will contract the space, and thereby tend to hasten the issue of a swarm. When bees hang long in clusters at the door of a hive they become in a sense morbid and inactive, and hence we prevent this by artificial swarming. If your gardener will summon courage enough to blow some smoke from old cotton rags into the hive, and then turn it on its crown and place an empty hive on and over it, rolling or tying a tablecloth round the junction of the two hives, and drum on the bottom one for four or five minutes, not more, you will have two hives which should be placed right and left of the present stand. If this had been done when the bees first began to hang out the swarm hive would by this time have been nearly filled with combs. The invention of artificial swarming is of great service to all who rightly practise it.

Bees Clustering but not Swarming (*A. C. N.*).—Take off the three glasses which are now full on your hive, and if you do not wish to take a swarm from it put larger supers in their places. As the bees are hanging outside it is very desirable to give them room enough inside. Wooden or straw supers are more readily entered by bees in a crowded hive than glass hives. If you wish to take a swarm no more supers should be put on. As the hive is probably well filled with honey, perhaps your better way will be to put a nadir below it, and take the honey from the top one in autumn, and keep the nadir for a stock hive.

Claiming a Swarm (*J. H. Howard*).—No man who has lost a swarm can compel a neighbour to give up a swarm that has settled in his garden, unless it can be proved that the swarm came from the claimant's apiary. In your case there were two strayed swarms settled in the same garden, and you could not point out either as yours. We knew an instance of a man claiming a strayed horse, not because he could identify it, but because he had lost one.

Drone Traps (*J. Hutchison*).—These are sold by the inventor, R. Aston, Upper Bar, Newport, Salop, at 2*s.* 6*d.*, or 2*s.* 8*d.* by post.

Bottles for Honey (*A. R.*).—Anyone who deals in preserve bottles and jars could supply you.

Young Linnets Plucking Young Canaries (*D. D. B.*).—It is not habitual with young Linnets to pluck or strip Canaries of their plumage the same as yours have done. Somewhat like Goldfinches, they are very handy with their "knives and forks," and if they see a misplaced feather, or one at all sticking out, they will have at it, a repetition of the plucking ensues, and frequent instances are known of birds being almost entirely stripped of their feathers. Canaries are at times equally culpable, both young and old birds. The Linnets may again repeat the mischief if the lot occupy the same apartment. The most effectual way to wean the depredators from plucking is to part them. You state you have "put the offenders into separate cages." You have acted wisely. There keep them, for it will check the propensity more than any other plan. As to placing them all together in the same cage for the more readily mating of them together when pairing time comes will not forward the birds. When you wish to breed with a pair (a cock Linnet and hen Canary), select a couple of healthy strong birds, and place them in cages side by side for a few days, after which, in the month of April, turn them into a breeding cage furnished with the necessary requirements for nest-building, and at the same time supply them daily with a generous diet, such as egg and bun crumbs and a mixture of seeds. This will tend to bring the birds into condition. A little extra attention in the way of keep, even before the two birds are placed together, will not be ill-bestowed.

REMARKS.

16th.—Frequent (and occasionally heavy) showers all the forenoon, but from 1 P.M. fine and pleasant the remainder of the day.

17th.—Morning fine and calm and till noon; frequent distant thunder in the early afternoon; slight thunderstorm with hail at 4 P.M., and short sharp showers all the afterpart of the day.

18th.—Rain in the night and early morning; distant thunder at 0.45 P.M., at 2.0, 2.15 and 4 P.M., with slight showers.

19th.—Thick fog in early morning, not clearing off till 10 A.M., after which time it was very fine and pleasant.

20th.—Wet till 10 A.M., afterwards fair, but not very bright, and looking very stormlike at 8 P.M.

21st.—A cold cloudy day.

22nd.—A very bright pleasant day throughout, but with a rather cold wind.

Another cool week, the 9 A.M. temperature about 3° lower than in the one preceding, but the mean of the maximum and minimum nearly the same.—G. J. Symons.

COVENT GARDEN MARKET.—June 23.

Very good markets now, outdoor produce being freely supplied, and Strawberries a lively trade, but prices rule low in consequence of the abundance and the heavy supply of Cherries from the Continent, which, however, will soon cease when the bulk of Kent produce is under consignment, as report speaks of heavy crops. The prices of Potatoes have slightly declined, although the Jersey supplies are nearly over.
